With the exception of the automatic feed all the above pumps are only worked for short periods at a time, they are therefore made as simple as possible, and doubtless are also very uneconomical as regards steam consumption, but there are three sets of engines—those for the dynamos, the refrigerators, and the fans—which work almost continuously, and waste a large amount of steam unless they are of the compound condensing type. The fans are of course only necessary where forced draught is required; they take up considerable floor space, and are rather bulky objects, but artificial draught seems to be growing in favour, and many modern steamers use it. On account of the high rotary velocity of the fan, its axis is subjected to severe stresses if placed athwartships, and if the vessel rolls quickly. These forces, due to gyroscopic properties of all fly-wheels, have caused frequent fractures of dynamo shafts, and such engines are now invariably placed parallel to the ship's keel, which plan ought also to be adopted with the fans. Refrigerating engines and chambers are now almost indispensable in passenger ships, and if to all the above mentioned auxiliary engines be added the steam-steering gear, which is frequently placed in the engine-room, it will be seen that the engineer of a good sized modern steamer may find himself responsible for the working of nine or more engines and appliances, half of which are constantly at work. In very large steamers many of these engines are fitted in duplicate, and in men-of-war their number is still further increased.

THE MANCHESTER SHIP CANAL, AND CANAL AND RIVER HYDRAULICS.

THE Manchester Ship Canal Company is promoting an omnibus Bill this session to obtain power to close the tidal openings in the estuary portion of the canal embankment; to amend the section compelling the discharge of the waters of the Weaver into the river Mersey by the Weaver tidal openings or Weaver sluices; to enable the company to raise about three acres of marsh land above the level of high water of spring tides; to extend the time for the construction of Warrington Dock; and for other purposes.

The Bill has been before a Committee of the House of Commons, presided over by the Hon. E. Blake, formerly a distinguished member of the Canadian Parliament, who now represents Longford as a Home Ruler, and three other members. The Bill occupied the Committee for fourteen days, and reminded the counsel and others who were retained of the fights of the last decade, when three years in succession the tenacious Daniel Adamson and his supporters came before Parliament and fought for forty days or twenty days as the case might be. They won in the first House in 1883 and 1884, to be defeated in the second, and failed to obtain an Act until 1885, by which time they had expended £150,000 in parliamentary and preliminary expenses.

This time the fight centred on the closing of the tidal openings. It will be remembered by our readers that it was contended by Liverpool in 1883, 1884, and 1885, that the scour due to the size of the receptacle for tidal water formed by the Upper Estuary was the factor to be relied on in keeping down the Bar, and so impressed were the Committee—of which the late Mr. W. E. Forster was chairman—of the advisability of maintaining as large an area as possible to be filled by the tide, that they caused the Ship Canal to be taken as far inland as the limits of deviation on the parliamentary plans allowed, and thus reduced as much as possible the amount of ultimate abstraction due to the river walls and embankments necessary for constructing the canal within the portion of the tidal limits through which it passes.

In 1883, and again in 1884, it was proposed to construct the waterway from Runcorn downwards by training and dredging a deep water channel through the estuary. The dread of accretion following on the stereotyping of a channel in the sandy upper estuary was understood to have been the chief reason for the ultimate rejection of the measure in those years. The Manchester case for relief from tolls and rates, which were said to be oppressive, was brought out so strongly during the proceedings, that, although the Committee of the Commons threw out the Bill in 1884, which had previously passed through the other House, they obtained an admission from the representatives of Liverpool that an alternative scheme was possible which would practically leave the estuary untouched. The promoters virtually adopted this scheme, and in order to allow the maximum amount of tidal water to flow in and out of the estuary on high tides, which all parties agreed were the important tides, for the purpose of scouring the channels and sandbanks of the Upper Estuary, as well as the Bar, only neap tides were excluded from the lowest reach of the canal. This reach is 21½ miles long, and its normal level was fixed at 14ft. 2in. above old dock sill at Liverpool, and tidal openings were constructed at that level, viz., 1ft. 4in. below the level of the average high water in the Mersey at Liverpool, which is 15ft. 6in above the old dock sill datum.

Three openings, each 600ft. long, have been constructed at Ellesmere Port, Weaver Mouth, and Runcorn, distant 3¼ miles, 10 miles, and 13 miles respectively, from Eastham. There are also two sluices at Eastham, ten at the Weaver, two at Old Randles, 15 miles above Eastham, all of which are 30ft. wide, and one at Walton Lock 20ft. wide, the latter being 19 miles from Eastham and close to Warrington. The top of the sluices, except at Eastham, are above high-water mark. The tide enters through the three tidal openings and the three locks at Eastham, the gates of which open automatically when the tide rises above the normal level of the canal.

It was supposed by many persons, having regard to the depth and capacity of the canal, that the tide would flow more rapidly along it than up the tortuous shallow channels of the estuary, and flow out rather than in through the tidal openings. Experience shows this supposition to have been erroneous, in spite of the depth of 26ft. and average width 160ft., although the sectional area of the three locks at Eastham is 4000 square feet, and of the canal 4134 square feet on the average. The tide reaches the sills of all the openings earlier from the estuary than from the canal, and continues to flow into the canal until after high water. At high water the gates at Eastham are closed, and the tide returns to the estuary through the three openings, and in order to lower the canal to the normal level rapidly, the sluices are lifted at Weaver and Old Randles.

A 21ft. tide opens the Eastham gates two hours and twenty minutes before high water. High water in the canal reaches the Weaver fifteen minutes and Walton Lock thirty minutes after high water at Eastham. The time of high water is a few minutes sooner at the various openings from Runcorn to Ellesmere Port in the estuary, but at Walton Lock it is thirty minutes later than in the canal.

The tidal openings have proved a source of great expense to the Canal Company, owing to the quantity of silt brought in by the tide and deposited in the deep water of the Canal. The dredging consequent on this silting is put at £30,000 a year, and it was stated that one-half of this was due to the tidal opening at Runcorn. The large number of craft employed in dredging and removing the silt was also complained of as impediments to navigation by trading vessels. The tidal openings are also objectionable, owing to the cross currents set up in the canal opposite them, both on the flood and ebb. The owners of large vessels will not allow them to navigate while the run of the tide lasts. For these reasons the Canal Company desires to close the openings.

The opposition to the Bill was based to a considerable extent upon the assumption that the company would raise the normal level of the canal, and thus deprive the estuary of additional scour, and injuriously affect the drainage of low-lying lands. At present the canal discharges automatically by means of the tidal openings; if they are closed the sluices alone are available. These are worked at the discretion of the company under the supervision of the Mersey Conservator. The company has submitted to a clause compelling it to lower the canal to the 14ft. 2in. level four and a-half to five hours after high water at the Weaver. This settles the question of level, but the question of loss of scour remains. The Ship Canal engineer stated that the total quantity of tidal water admitted into the canal on a tide flowing 20ft. 9in. at Liverpool was 11,022,302 cubic yards, and apportioned it as follows:—At Eastham, 3,157,090 cubic yards; at Ellesmere tidal opening, 885,214 cubic yards; at Weaver tidal opening, 4,924,927 cubic yards; at Runcorn tidal opening, 1,783,070 cubic yards. To this was added 1,000,000 cubic yards as the average contribution of fresh water from the rivers during the tide.

It was admitted that the volume of tide entering the canal after the closing of the openings through Eastham Locks, even if the sluices there are raised to augment the inflow and diminish the speed of the current, will not be more than 7,000,000 cubic yards, as compared with 11,000,000 cubic yards at the present time, and that, practically, high water at Eastham will be the high-water level throughout the canal, whereas now there is an increment due to the momentum of the tide of upwards of 2ft. It was contended that under the existing circumstances the tidal water taken into the canal was simply so much abstracted from the estuary, and that when the openings were closed the estuarial tide would rise higher and no scour would be lost to the channels. This view was urged more particularly in respect to the portion above Runcorn.

The Mersey Conservator, in his last and also in his penultimate report, quoting from figures with which he had been supplied, stated that the level of high water of spring tides at Warrington had fallen of late years by more than one foot. It was stated that this represented about 2,000,000 cubic yards in the estuary, and that 1,783,070 cubic yards was taken into the canal at the Runcorn opening. It was therefore assumed that the lowering of the tidal level was due to the tidal water being diverted into the canal, and that the supply from below is limited. On the other hand, it appeared, from observations taken of the tides during the current year, that the increment at Warrington was as high as of yore; and thus this assumption seems to be disposed of. In neither case were the observations made for a sufficiently long period to warrant the assumption that so great a change had been brought about in the *régime* of the estuary by any changes wrought by the Canal Company.

The capacity of the Mersey estuary is 960,000,000 cubic yards; this includes the water remaining in the deeps at low water, as well as the portion from which the tide has ebbed at the lower end before the period of high water is reached at the upper end. The inflow of a 21ft. tide is taken as 710,000,000 cubic yards; of the average tides, 495,000,000 cubic yards. Before the Liverpool bar was lowered and practically controlled by dredging, it was urged from time to time that the abstraction of a few million cubic yards from the highest tides might cause ruin to the port. This contention is vain at the present time, when instead of 10ft. or thereabouts, as was the case formerly, there is upwards of 20ft. over the Bar at low water. The case, however, is different in the portion of the estuary above Runcorn. The capacity of this is given as 23,000,000 cubic yards, and a loss of 1,750,000 cubic yards flowing through the Runcorn tidal opening is worthy of all consideration. The trade of the Upper Mersey is a large one, and at Weston Point, Runcorn, Widnes, and Warrington, will aggregate something like 2,000,000 tons per annum, a large portion of which is carried on the estuary. It is therefore necessary to consider in what way a change in the *régime* of the Ship Canal could be made so as to safeguard the interests of these ports.

It was proposed by the Canal Company that the works for closing the tidal openings should be of timber, and of a character to be easily removed if it was found that any damage accrued to the estuary which in the opinion of the Mersey Commissioners, represented by their acting conservator, Admiral Richards, could be traced to the alterations following upon the passing of the Bill.

The Committee were anxious to go further, and to make the erection of these works subject to the consent of the Mersey Conservator, but after hearing Admiral Richards they determined to pass the preamble, and that the works should be erected on the sole authority of Parliament.

Provision has also been made for the discharge of as much water as is practicable from the sluices above Runcorn.

As we have seen, high water in the Mersey at Walton Lock is half an hour later than high water in the canal. In order to discharge from the canal at this point, it is necessary to retain the water in the canal for half an hour before the river falls low enough to enable it to flow out of the sluice way. Twenty minutes later the sluices at Old Randles are to be opened and kept open until the canal reaches its normal level, the Weaver sluices being used in addition to those above mentioned, in order that the obligation to lower the water in five hours' time may be fulfilled. This is a beneficial arrangement, and if during low tide the fresh water is discharged from the sluices high up the estuary, a beneficial effect on the channels ought to be ensured.

There is one other point in connection with the closing of the tidal openings which is of great importance to the canal, and those who use the waterway, viz., the effect on the speed of the current which will follow when 7,000,000 cubic yards of water enters at Eastham and flows along the canal to fill its length of upwards of twenty miles to Latchford, and also the Weaver estuary, which from the large quantity flowing in through the Weaver opening, appears to demand a considerable volume of tidal water. The speed of the current will naturally be increased through the Eastham Locks, and as much of the traffic can only pass these at high water, the increase in speed will be objectionable, to say the least of it.

At the present time the Shropshire Union train of barges is not navigated through the locks at the time when the current runs strongest, but remains in the river until it has moderated, whenever the number of barges exceeds three or four. The currents in the canal at the present time are found to be as follows, viz.:—On a 15ft. 6in. tide the mean is 0·91 miles an hour, the maximum 1·10 miles an hour. On a 19ft. tide the mean is 1·13 miles an hour, the maximum 1·41 miles an hour. On a 21ft. tide the mean is 1·18 miles an hour, the maximum 1·50 miles an hour. It is calculated that these velocities will be increased on the closing of the openings, and will become:—On a 15ft. 6ft. tide there will be no perceptible increase. On a 19ft. tide, mean 1·66 miles an hour, maximum 2·06 miles an hour. On a 21ft. tide, mean 2·24 miles an hour, maximum 2·84 miles an hour.

The narrowest section of the canal extends for nearly half a mile in length through the rock cutting at Pool Hall, two miles from Eastham. Here the bottom width is 120ft., the surface width 129ft., and the sectional area at the normal level of the canal 3237ft. Under existing conditions on a 15ft. 6in. tide the mean velocity through this length is 1·61 miles an hour, and the maximum 2·61 miles an hour. On a 19ft. tide the mean is 2·05 miles an hour, the maximum 2·55 miles an hour. On a 21ft. tide the mean is 2·17 miles an hour, the maximum 2·86 miles an hour.

It is calculated that these velocities will be increased on the closing of the tidal openings, and will become:—On a 15ft. 6in. tide, no increase perceptible. On a 19ft. tide, mean 3·00 miles an hour, maximum 3·74 miles an hour. On a 21ft. tide, mean 4·12 miles an hour, maximum 5·13 miles an hour. The above figures are given treating the flow as due to current alone. It is hoped that the propagation of the tidal wave in the canal will be facilitated by doing away with the cross currents set up by the water flowing in through the tidal openings, and that the maximum velocity may be diminished owing to the acceleration of the tidal wave. In the event of the closing of the tidal openings, which will no doubt be done by degrees, it is to be hoped that careful observations will be taken of the effect on the currents in the canal. It is seldom that such an opportunity of testing the theory of hydraulics by experiment on a large scale occurs. The British Association has frequently done good service in matters of a somewhat similar character. We direct the attention of their Committee to the proposals of the Canal Company, in the hope that they will arrange that the opportunity of advancing our knowledge on the question of tides and currents may be utilised as fully as possible.

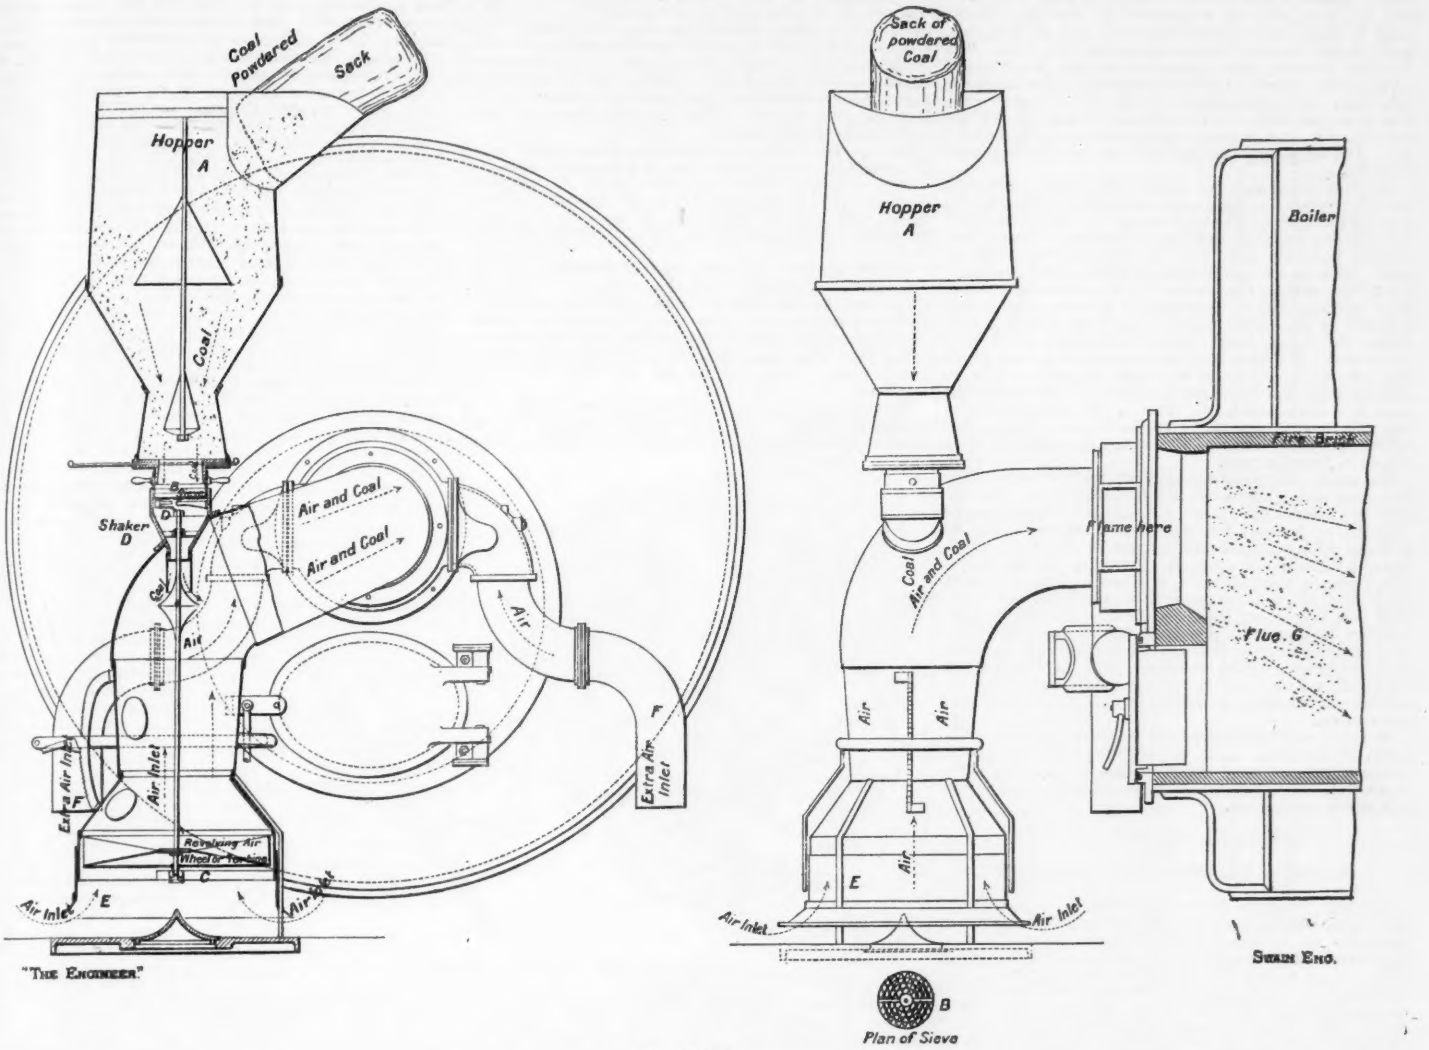
THE GENERAL POLICY OF THE AMALGAMATED SOCIETY OF ENGINEERS.

UNDER the above heading, in the forty-fifth annual report of the Amalgamated Society of Engineers, recently sent out to the members, Mr. John Anderson, the general secretary, offers some observations which are of interest. He states that during the four years of depressed trade much caution has had to be exercised to avoid ruptures with the employers.

To give the members an idea of the enormous expenditure incurred during 1893, 1894, and 1895, which caused the executive so much anxiety whilst having to resist numerous encroachments, no less than £842,324 was disbursed in the various benefits, £381,993 being required for donation alone, and £12,532 for contingent benefit, the latter amount clearly indicating that, although abstaining from an aggressive policy, all their energies had to be put forth to defend and maintain their position, and proved conclusively that the policy adopted was not a peace-at-any-price one. It was gratifying to know, however, that although such a vast amount—unparalleled in their history—had been spent, they had come through this anxious period practically unscathed, as at the beginning of 1893 their accumulated fund was £214,344, whilst last December the total worth was £206,115, or only £8000 less; and no doubt this would have been converted into a surplus but for the stirring events at Belfast and on the Clyde towards the end of the year, when the Council encouraged and helped forward the movement for a restoration of the wages in operation prior to the period of bad trade setting in, which policy had been initiated in other districts as well, owing to the returning prosperity about the middle of the year, and was now being pushed forward with

THE WEGENER POWDERED FUEL APPARATUS FOR STEAM BOILER FURNACES

MESSRS. BRYAN DONKIN AND CO., LONDON, ENGINEERS



Figs. 1 and 2

splendid results. The Society were now making wonderful progress, as in the three months from the closing of the year's accounts they had had a rapid influx of new members, and had now reached the grand total of 80,208 members.

WEGENER'S POWDERED FUEL BOILER FURNACE AND APPARATUS.

THE accompanying engravings illustrate a new form of apparatus designed by Herr Wegener for burning finely pulverised coal, and burning it in such a way that the quantity is automatically varied with the quantity of air admitted for supporting combustion. The apparatus has been in use some time on the Continent, and is now in use in the works of Messrs. Bryan Donkin and Co., where it has been shown in operation.

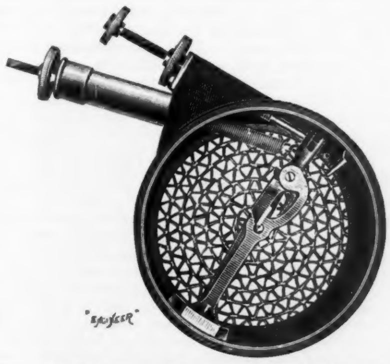


Fig. 3—WEGENER POWDERED FUEL APPARATUS

Our engravings show the apparatus in detail as applicable to any boiler, and it may be described with reference to its operation.

The small sacks of powdered coal, weighing about ¼ cwt., are put into a conical hopper A. The powdered coal gradually falls out of the sacks as required into the hopper, and then on to a sieve B, about 5½in. diameter, with small openings in it—see also Fig. 3. The powdered coal would not continue to pass through this sieve with certainty without continual tapping, and this is done in the following way:—

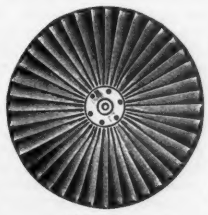

Fig. 4

Immediately beneath the hopper, and level with the boiler-house floor, is an air pipe E, about 20in. diameter, through which nearly all the air for combustion enters. As it enters, it is made to pass through the blades of an air-wheel or turbine C, and this passage of the air causes the latter to revolve like a smoke-jack. On the axis of this air-wheel there is a little knocker which taps the sieve from 150 to 250 times per minute, causing the powdered coal to descend vertically through the sieve, meeting the air for combustion as it ascends vertically. The powdered coal and air for proper combustion in this way get mixed thoroughly together, and pass on into the boiler flue, each particle of coal being surrounded by air. There is no grate, and there are no fire doors, and the stoking simply consists of putting a sack of powdered coal from time to time into the top of the hopper, and seeing that the right amount of air is going in for combustion. If there is not sufficient air for proper combustion entering through the main opening, as shown by a little smoke, there are two other smaller pipes where additional air can be admitted, each kind of coal requiring a somewhat different amount of air. The only object of the air-wheel revolving from 75 to 125 revolutions per minute, is to shake the sieve and cause the powdered fuel to go into the furnace in the quantity desired. When more steam and coal are required a greater knock is given to the sieve, and more powdered coal is burnt; when less is required a less shake is necessary. A screw adjustment for this knocking device is provided to regulate the amount of coal entering, which is done by turning a thumb-screw. The attendant can look after several boilers. An analysis of gases of combustion proves that the combustion is excellent and the amount CO_2 is higher than with ordinary furnaces.

Mr. Bryan Donkin made a careful test on a Cornish boiler at Berlin in March last, first with an ordinary grate and ordinary hand-stoking; and, secondly, a few days after, on same boiler, same conditions, and same coal, but with Wegener's patent system of powdered or molecular firing.

The following are the particulars and results of experi-

Results of Trials.

Trial.—			
Experiment number	I.	II.	Comparisons.
Date of experiment, 1895	March 29th	April 1st	
Conditions, with or without Wegener's apparatus	Without	With	
Duration of trial, continuous, hours	7·1	6·66	
Weather	Wet	Fine and dry	
Mean steam pressure (from tested Bourdon gauge every quarter hour), lb.	82	83·4	Same steam pressure
Coal.—			
Total coal burned, lb.	1600	1410	
Coal burned per hour, lb.	225	211·5	About same quantity coal
Coal burned per hour per sq. ft. of fire-grate, lb.	16·3	—	
Moisture in coal, per cent.	9·0	1·2	
Ashes and clinkers in coal, per cent.	14·8	Assumed at 15 to 19	
Water.—			
Mean temperature of feed-water entering boiler, Fah.	63°	48·2	
Total feed-water evaporated, lb.	7928	10,517	
Water evaporated per hour, lb.	1117	1,577	
Water evaporated per hour per sq. ft. heating surface, lb.	2·23	3·15	41 p.c. more water evaporated per sq. ft. per hour
Evaporation.—			
Lb. water evaporated per lb. wet coal, from temperature of feed, lb.	4·956	7·46	50 p.c. more evaporation with Wegener's app.
Lb. water evaporated per lb. wet coal, from and at 212 deg. Fah., lb.	5·90	9·00	52 p.c. more evaporation with Wegener's app.
Lb. water evaporated per lb. dry coal, from and at 212 deg. Fah., lb.	6·48	9·11	40 p.c. more evaporation with Wegener's app.
Calorific value of coal, lb. water per lb. dry coal, from and at 212 deg. Fah., lb.	12·00	11·85	About same heating power
Thermal efficiency of boiler = $\frac{\text{actual evaporation}}{\text{calorific value}}$, p.c.	54	77	42 p.c. more efficiency
Chimney and gases.—			
Mean position of damper	Full open	Full open	
Temperature of furnace gases at end of boiler tube, Fah.	above 750°	above 750°	
Temperature of furnace gases at base of chimney, Fah.	438°	418°	
Draught of chimney in side flue at front of boiler, inches of water	0·41in.	Water gauge oscillated from a slight pressure to a vacuum	
Draught of chimney at base of chimney, inches of water	0·61in.		
Mean analysis of furnace gases, taken every quarter hour: CO_2 p.c. by volume	8·73	15·35	Better combustion with Wegener's apparatus, more CO_2, less O and no CO
O ,, ,,	8·13	3·14	
CO ,, ,,	0·88	0·0	
Temperature of air in boiler-house, Fah.	54°	58°	
Smoke.—			
Total number of times smoke observed	70	7	See curve for details of smoke observations
Total duration of smoke, minutes	105	6	
Mean intensity of smoke (Mr. D. K. Clark's smoke scale) number	7	5	

In this experiment the bars were rather too wide apart for the small coal used to get the best results.

ments on a Cornish boiler, at the Artificial Stone Works, Berlin :—

General particulars.—Two experiments were made on the same boiler, at the same steam pressure, and with the same coal—powdered in second trial. The boiler is 5ft. 7in. dia. by 28ft. 4in. long, with one flue or tube 2ft. 7½in. dia. It was made in Berlin about November 1892; and all flues, &c., were cleaned about six weeks previous to the trials. The direction of smoke was—through tube, split to sides, and return under bottom of boiler to chimney. The latter was 82ft. high. The total heating surface was 500 square feet; and in the first trial with the ordinary furnace, the fire-bars were 5ft. 3in. long, making a total grate area of 13·8 square feet. The top of the boiler was fairly well covered to prevent radiation.

The first experiment was made on March 29th, 1895, with the ordinary furnace, using a very small English flaming coal —about ½in. pieces. The fire-bars were of the ordinary cast iron pattern, ¾in. wide, with $\frac{5}{16}$in. air spaces. The coal was weighed in sacks previous to the trial, and was stoked by hand. The fire was stoked thirty-five times and raked forty-eight times, making the opening of the fire-door eighty-three times in seven hours = once every five minutes. The fire was kept 2in. to 3in. thick; and the coal burned with a long flame. The fire was kept low at the beginning and end of the experiment. The feed-water was measured in a tank, which had been previously found to contain 132 gallons up to an overflow hole; and the height of water in the boiler was the same at the start and finish. Part of the steam generated was used for an engine, the remainder being allowed to blow off by the safety valves. The steam appeared dry when turned on from ½in. pipe.

The second experiment was made on April 1st, 1895, using the same coal as above, but very finely powdered. The fire-bars and furnace were taken out, and the boiler tube lined with 3in. of fire-brick for 11ft. 6in. from front of boiler, and provided with zig-zag baffles to prevent the flame going straight through—see drawing. The powdered coal was put in a hopper in front of boiler, and passed through a sieve, about 5¼in. dia, with triangular holes, about ½in. side. The sieve was tapped constantly by the axle of a revolving air-wheel or turbine, about 20in. diameter, which was driven by the current of air going through it into the boiler tube, to mix with the powdered coal for combustion. The speed of this air-wheel varied from thirty to eighty revolutions per minute, corresponding to 100 to 250 tappings of the sieve per minute.

Grinding coal into fine powder increases first cost of coal about 10 per cent. As to the economy with this system, compared with that of ordinary hand-stoking, this varies much with the different circumstances, kind of boiler, fuel, and rate of combustion.

MALLAIG RAILWAY AND HARBOUR.

THE new line to be formed from Banavie to Mallaig constitutes an extension of the West Highland Railway, and will act as an important feeder to that company's system. The district to be served by the new railway is at present wholly devoid of such facilities, and an important traffic with the island of Skye is assured, whilst from the fish conveyed an important revenue should result. The route, moreover, is rich in scenic grandeur, and cannot fail to attract large numbers of tourists and holiday makers, whilst the numerous lochs in the neighbourhood afford such excellent fishing that sportsmen will not fail to avail themselves of this means of gaining so favourite a spot.

The Mallaig line will be a single one throughout its entire length of 39 miles 5 furlongs 3·50 chains, and is estimated to cost £318,057 10s., whilst the pier and breakwater are estimated at an additional £45,000, bringing the total expenditure up to £363,057 10s. The route traversed will be apparent from the accompanying map. Leaving the West Highland Railway's Fort William and Banavie branch near the latter place, the new line strikes due west, and, running through Corpach, skirts the northern shore of Loch Eil for its entire length, taking Corribeg and Kinlocheil on its route. The first point of interest reached is Glen Finnan, at the head of Loch Shiel, whence, still pursuing a westerly course, the line takes the southern shores of Loch Eilt, and runs on to Kinlochailort. The heads of Lochs Airlot and Nan Uamh are then passed, and turning north near Arisaig, the railway runs between Loch Morar and Bourblach, finally reaching Mallaig at the southern end of the Sound of Sleat, near the entrance to Loch Nevis, its terminus.

The principal features of interest along the route will be the steel swing bridge over the Caledonian Canal at the point of crossing between Banavie and Corpach, and the viaduct at Glenfinnan, 120ft. high, and consisting of nineteen arches of concrete, each having a span of 50ft. The remaining works will comprise two or three other viaducts, having arches of similar span to the number of six to ten, and three short tunnels which will be concrete lined. The general design of the viaducts may be briefly stated to be—Piers, 6ft. wide at the springing, with batters of 1 in 50, the arch being 2ft. 6in. thick at the crown, and the spandril walls of similar thickness. The concrete in the interior of the viaducts will be mixed in the proportion of 5 to 1, whilst 1ft. of fine 4 to 1 concrete, with a granolithic face, will be employed for the exterior portions.

The fencing of the line will be formed by half-round posts cut from logs 6½in. diameter. Each post will have a length of 6ft. 6in., they will be spaced 6ft. apart, centre to centre, from those on either side. The posts will be sunk by pitting them 2ft. 6in. into the ground, the earth being subsequently punned in hard all round. The posts will be charred at ground level to prevent decay. The rails will be four in number, each rail being sawn square, 4½in. by 1in., and fastened to each post by two 3in. nails.

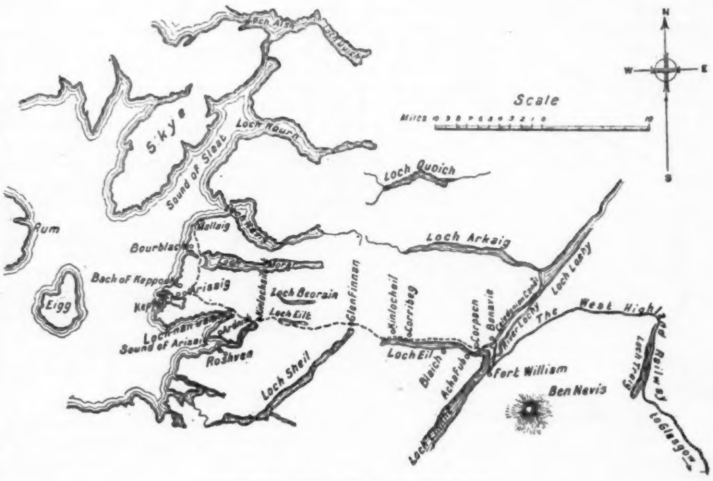
Where wire fencing is employed, seven lines of galvanised solid wire, No. 6 gauge, will be used, the height of the top wire being 4ft. from the ground level. The standards will be of malleable iron, $2\frac{1}{10}$lb. per foot, and spaced 7ft. apart from centre to centre, twelve straining and winding pillars of malleable iron being erected for each mile. The occupation roads and fences will have iron gates 10ft. wide by 4ft. high, hung on larch posts 9ft. long and 9in. diameter.

The width of the cuttings and embankments at formation level will be 15ft., whilst the ditches along the route will be 2ft. and 6in. wide at the top and bottom respectively, and 2ft. deep. The concrete used throughout the undertaking will consist of five parts of stone—broken to pass through a 2in. ring—with one part of Portland cement, and a suitable proportion of sand. The tunnels, which will be furnished with recesses every twenty-five yards, will be lined with fine concrete composed of four parts of stone to one part of Portland cement, with the requisite amount of sand. The mortar employed on the work will be formed of one part of Portland cement to three parts of sand. The line will be of the customary 4ft. 8½in. gauge, with 84 lb. steel rails, the sharpest curves being those of twelve chains, with one or two exceptions, in which 10-chain curves are unavoidable. The steepest gradient will be 1 in 50, and the estimated time for completion is three years. The occupation roads throughout the contract will have a width of 12ft., and will be metalled for a width of 9ft. with 4in. hard stones for a depth of 6in., overlaid by 3in. of stone broken to pass through a 2½in. ring, and bonded with fine gravel.

The Portland cement is specified to be ground extremely fine, and to leave not more than a 7 per cent. residue on a sieve with 2500 meshes per square inch. The weight is required not to be less than 112 lb. per imperial—striked—bushel, and after an immersion of seven days in water, briquettes are to bear a tensile strain of 400 lb. per square inch.

It only remains to be added that all footpaths will have 4in. bottoming, overlaid by 2in. of fine gravel or whinstone chips, and that the ballast of the permanent way will be formed of stone broken to pass through a 2½in. ring, laid 7in. below the bottom of the sleepers and to within 6in. of the top of the rails. The rails themselves will be in 30ft. lengths, twelve sleepers being laid per rail and 40 lb. chairs being employed.

Turning now to some brief notice of the harbour to be formed at Mallaig: an area of 40 acres having a minimum depth of 10ft. at low water, or of 35 acres affording 20ft. at low water, will be obtained. The breakwater, which will be formed of 10-ton — 5 to 1 — concrete blocks, and will be 500 yards long, will run in a northerly direction from near the site of the present small pier to the "Red Rocks," and will shelter the harbour from the south-west or prevailing winds. The work will be executed on the sloping concrete block system, and is estimated to occupy one year. A pier of pitch pine 450ft. in length, with an arm 200ft. long at its extremity running in the direction of the breakwater, is also included in the scheme. The width of the pier and arm will be 35ft. and 25ft. respectively, and the whole will be carried on 12in. piles. The pier will be of ordinary construction, and calls for no special remark. It will be furnished with a travelling crane. An hotel at Mallaig is also included in the scheme, and will be erected on a site granted by Lord Lovat free of charge.



BANAVIE AND MALLAIG RAILWAY

The line will be furnished with stations at suitable points, and, as the property of the West Highland Railway Company, will be worked by the North British Railway Company. The engineers of the Mallaig railway and harbour are Messrs. Simpson and Wilson, C.E., of Glasgow.

In regard to the financial arrangements of the undertaking, some recently issued correspondence between the Treasury and the West Highland Railway Company fully details the guarantee and other provisions. The memorandum relative to the Bill which the Government propose to introduce this session sets forth that in June, 1892, the then Government stated their readiness to introduce a Bill guaranteeing a dividend of 3 per cent. for thirty years on the estimate for the railway—£260,000—and at the proper time to ask Parliament to vote £30,000 towards the harbour. The offer was subject to four conditions, viz.:—(1) "The promoters must obtain an Act for the construction of the railway and harbour." (2) "They must enter into an agreement with the North British Railway Company to work and maintain the railway in perpetuity for 50 per cent. of the gross receipts." (3) "The remaining 50 per cent. of the gross receipts must be applied in the first instance towards paying a dividend of 3 per cent. on the £260,000." (4) "The plans of the harbour works must be approved by the Government."

The West Highland Railway Act, 1894, satisfies the first two conditions, whilst in regard to conditions Nos. 3 and 4 an agreement has been signed between the Treasury and the West Highland Railway Company agreeing that :—(*a*) "From the date of the opening for traffic of any portions of the railway the company will in the first instance apply 50 per cent. of the gross revenue arising therefrom, after paying thereout of Government duty, and poor, school, county, and other rates and taxes, towards the payment of a dividend of 3 per cent. on the above-mentioned capital of £260,000, and that the Treasury will guarantee for thirty years from the date of the opening for passenger traffic of the railway 3 per cent. on £260,000, and will pay half-yearly to the company such sum as along with the 50 per cent. of the gross revenues as above-mentioned will enable the company to pay a dividend of 3 per cent. on £260,000." (*b*) "That the Government will pay to the company £30,000 towards the cost of the construction of the pier and breakwater, on the completion thereof being certified by the Board of Trade."

The conditions laid down by Government being thus fulfilled, the Bill proposes to make formal provision (1) "For the guarantee by the Treasury of the dividend." (2) "For the payment of £30,000 on the completion of the pier and breakwater."

GLOUCESTER WATERWORKS.

THE operations for supplying Gloucester with water from Newent are rapidly nearing completion. The well sinking and the headings are finished, and the contractors have cleared away their plant. A temporary pumping station is being erected away from the well, and when the pipe laying is completed, this plant will be available for a time for the supply of water to Gloucester. The permanent buildings, in course of erection, will consist of an engine-house, boiler-house, workshop, and coal store. The well is 168ft. 6in. deep, and at the depth of 145ft. there are two headings 6ft. high and 5ft. wide, running, one in a westerly, and the other in a north-easterly direction. Needless to say, these headings, which are respectively 145ft. and 117ft. long, increase the flow of water from the sandstone. A 14in. main has been laid the whole of the distance from Newent to Gloucester, with the exception of about 1¼ miles of the route. A covered reservoir, 100ft. long by 60ft. wide and 18ft. deep, and capable of holding 675,000 gallons of water, has been constructed at Madam's Wood, Upleadon. About two-thirds of the walls of the reservoir are erected, and the work of digging out the basin has been begun. This will take about a fortnight to complete. The reservoir will be covered with a low roofing of rolled joists, and arches of cement and concrete. The site is three miles from the well and eight miles from Gloucester, and is 250ft. above the sea level. The water from the well will, in the first instance, be pumped into the reservoir, out of which it will run by gravitation into Gloucester. The present supply of water to the city is from Whitcomb reservoirs, and the new 14in. main from Newent has been connected with the old 12in. main at Gloucester Cross.

On entering the city at Westgate Bridge the new main has been carried under the paved footpath, but at Over a steel lattice girder bridge has had to be constructed to convey the pipes across the Severn. This bridge, which has just been floated over the river, was built on the Gloucester side of the stream. It is 222ft. long, with a clear span of 219ft. Its weight is 60 tons, and crosses the Severn between the railway and the road bridges. The depth of the centre of the girder is 17ft., with a tension boom of 6in. of camber, and a top compression boom of 8ft. The water pipes will be carried over on the floor of the bridge on rolled joists, fifty-two in number. There are two piers, 9ft. high, one on either side of the river, upon which, when completed, the bridge will rest. The piers consist of four screw piles 15in. in diameter, which have been sunk to the blue lias, a depth of some 40ft. Fittings have been provided at one end of the bridge to allow for expansion. The work of floating this huge structure was successfully accomplished on a 10 o'clock p.m. tide. One end of the bridge rested securely on two "longboats"—failing negotiations for a lighter—lashed together, and the other end was supported on a trolley on rails. Winches erected on the opposite bank were got to work, and the boats, with the bridge attached, were hauled safely across the river in the space of about twenty-five minutes. All that now remains to be done is to hoist the bridge into position on the piers by screw jacks. Mr. W. Fox, London, is the engineer.

The pumping machinery supplied by Messrs. Summers and Scott, Gloucester, consists of two compound engines of the inverted cylinder type, arranged with a fly-wheel between them. The diameter of the high-pressure cylinder is 16in., stroke 4ft. 6in.; the diameter of the low-pressure cylinder is 28in., stroke 4ft. 6in.; the diameter of the well pump 14¾in., stroke 4ft. 3in.; diameter of the double-acting bucket pump 10½in., with 4ft. 6in. stroke. The high-pressure engine drives a lift pump in the well, by means of a bell crank lever worked from the crank pin by means of a connecting-rod. The low-pressure engine drives the horizontal force pump direct from the crank by means of a similar connecting-rod. The bell crank is fitted at the inner end with a balance of sufficient weight to balance the pump-rods and bucket and half the load. The force pump is a double-acting pump fitted with a gun-metal liner and bucket. The framing consists of four box section girders joined together by strong transverse pieces. Two of these girders have the pedestals for carrying the crank shaft cast on them. At the front end the girders carry the A-shaped frames for supporting the cylinders, and at the outer end the pedestal brackets for the pump bob centre and the force pump. The A frames have the slide bars cast in them, the cylinders being secured to the top by means of strong bolts. The fly-wheel is 16ft. diameter, and about 11 tons in weight, and fitted with a special arrangement of hand barring gear. A suitable platform, handrail, and ladder are fixed round the engines at a convenient height for getting at the slide bars and valve gear, and are made of such pattern as to suit the style of the building generally. A suitable polished handrail is also provided on the ground level where necessary, to fence off the moving parts of the engines. There are three Cornish steam boilers, 22ft. long by 6ft. diameter, and an economiser on the Green principle. There is a travelling crane at the top of the engine house, for lifting the heaviest or any part of the machinery. The engines are constructed to run at eighteen revolutions per minute, and may be increased to twenty-five revolutions, if necessary.

THE ANNUAL DINNER OF OLD STUDENTS OF KING'S COLLEGE, LONDON, will be held at the Holborn Restaurant, on Monday, June 29th, with Sir Benjamin Baker, K.C.M.G., LL.D., F.R.S., president of the Institution of Civil Engineers, in the chair.

LOCOMOTIVES FOR BULGARIA. — The Secretary of State for Foreign Affairs has received a despatch from her Majesty's agent and Consul-General at Sofia, in which he states that tenders for locomotives required for the Bulgarian State Railways are invited by the Bulgarian Government. A copy of the conditions of tender is enclosed in Mr. Elliot's despatch, and may be viewed at the Commercial Department, Foreign-office, between the hours of 11 a.m. and 6 p.m.

WHEELER-STERLING PROJECTILES.

The Wheeler-Sterling Company began the manufacture of armour-piercing projectiles about twelve years ago, and has achieved remarkable success, as is well known by those who follow the records showing the recent development of armour and its attack. It would be hardly necessary then to mention such a fact were it not that the methods of stating what has been achieved differ in the States and in England, that is to say, the matter is stated in stronger terms in the States. Diffidence and modest appreciation of success is, no doubt, rare in England, and it is not surprising if it is a drug in the American market. There is, however, a certain difference in the way English and Americans express themselves. If an English manufacturer stated publicly as an undoubted fact that he personally was the best of his kind, it would be thought bad taste; and the result of such a statement being made by an American in England has been that the speaker was put down, if not as an impostor, at all events as a man whose "geese were swans," and, practically, what he said after that carried no weight. Now this estimate was a mistake. The Englishman, no doubt, at times thinks as much of himself as his American cousin, and the fact that he keeps it to himself is more a matter of taste and custom than of humility. We prefer the English custom, but that may be due to our insular prejudice. The other—we will not call it the American custom, but the custom which is to be met with in America—is perhaps the more truthful and simple one. What, however, concerns us here is that we must be on our guard not to assume that an American product or man is a "fraud" because inflated language is used. We have before us a case in point—a report of the Wheeler-Sterling Projectile Company. It contains language that would prejudice English readers; but if they put down the report and conclude that the projectiles do not deserve attention, we believe that they will make a great mistake.

For example, on page 21 we read that Commodore Sampson considers the American shells the best, and that the "Wheeler leads." "This expression," it is remarked, "coming from such a high authority, settles all doubt as to the superior quality of the Wheeler-Sterling shells." "That America can beat the world in the manufacture of projectiles," we are told, is "a fact." A reader naturally says if an American officer's opinion on American projectiles is thus to settle the matter *ipso facto*, the facts in this pamphlet must be largely discounted. Nevertheless, our sober belief is that the Wheeler-Sterling projectiles have at the present moment the best record to show of any, and we consider Commodore Sampson a very high authority.

Again, on page 20 the Sterling Steel Company "has excelled the projectile makers of the world," and "is furnishing the Government with a grade of shells which no armour made in this or any other country can withstand." Now this statement is so unbusiness-like that it is difficult to deal with. It has no value unless some proportion is stated between the shot and plate. On the 14th of last September, a 14in. Carnegie-Harvey plate kept out all Wheeler-Sterling projectiles, including one from a 12in. gun, until a 13in. shell was fired at it with 1800 foot-seconds, a blow which completely outmatches such a plate. We recently gave reports and photographs of Krupp plates which exhibited still more remarkable powers. Hardened faced plates, so far as records go, keep out all projectiles—including the Wheeler—better than untreated steel plates kept out the shot of their own time. There is nothing in the above, however, that could well mislead anyone. A more serious matter is the following, which, however, may not be intentional. We are told that naval enthusiasts claim that "another revolution in the armouring of warships will be brought about by the new Wheeler-Sterling shell." Then follows a statement that no shells in the past carrying explosives have "ever succeeded in penetrating even the thin armour of the non-vital sections of the ship," but that a Wheeler shell of 13in. had penetrated a 7in. steel plate and backing, and was recovered practically uninjured. This is considered a proof that it could have carried a high explosive safely through the armour, although it adds, "No explosive was used, of course, in to-day's test." Some of the trials with "semi-armour-piercing shells" would give the impression to a casual reader that bursting charges were employed in the shells, but we do not think that they were, in most cases; or, indeed, that this impression is intended to be conveyed. In the trials when 5in. shells burst after passing through 2in. of steel plate, the shells may have only performed what has been done years ago in this country. We are told that the United States requirements, now arrived at based on the great success achieved with the Wheeler shells, are expressed as follows: "That the shells should successfully perforate a nickel steel plate one-half a calibre thick," and then be in a condition to be exploded. The plate is apparently not a "Harveyed" one. The plan appears to be to charge the recovered shell and burst it. In our own British official records of trials we read on November 13th, 1891, a Palliser 6in. projectile filled and fuzed, and a cast steel armour-piercing common shell passed through a Brown steel plate 4in. thick, bursting in their passage; some Palliser fragments were left behind, but the whole of the steel sheel fragments passed through. This is an old story of four and a-half years ago; the shells were very inferior, of chilled iron and cast steel, but they drove their fragments through steel two-thirds of their calibre, so that practically even when the cast steel shell does not pass intact through the armour it so bursts that its explosive effect does not carry any fragments back outside, and must therefore be fairly through the armour. Five-inch shells getting intact through 2in. of steel four years later is no great achievement, especially as it would be difficult to prove that the shells were not exploded in their passage like what we may call their rude English forefathers.

What should have been done is not to fire an empty shell through a plate, and argue from its non-deformation that the bursting charge would not have exploded, but to fire a shell charged, and show that it can be recovered with its charge not fired. At all events, it is quite a mistake to suppose that the thin armour employed on the non-vital parts of ships could not be attacked successfully hitherto by semi-armour piercers, or armour-piercing common shell. This has been understood for many years in England, but the hit must be fairly direct, and the shell from its small capacity, has a greatly reduced bursting charge. This armour, however, keeps out common shell with really large bursting charges, and probably keeps out the semi-armour piercers at any considerable angle.

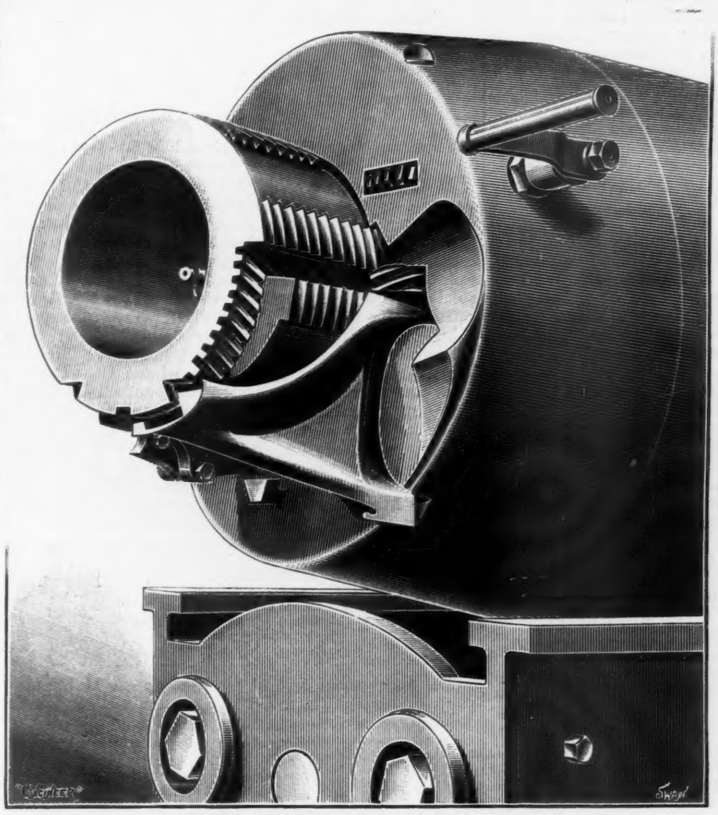
We must now conclude by noticing the strong features which belong to the Wheeler-Sterling shells. They are far too important for us to be able to ignore them safely. We have already said that their record is, we believe, the best of any yet achieved. They are considered to have beaten the Carpenter projectiles; and in larger calibres than 6in. the Carpenter have, so far as we can judge, beaten the Holtzer, and the Holtzer were the accepted international standard for 6in. calibre, and may be expected to be good for higher calibres. The Wheeler have, indeed, produced very remarkable results; they have passed nearly or quite unbroken through Harveyed armour; for example, a 12in. projectile perforated a 14in. nickel steel Harveyed plate with 1858 foot-seconds velocity, with only a broken point on February 24th, 1895. Again, we are told that perforation was achieved by 12in. projectiles through a 14in. Carnegie plate at 15 and 20 deg. with the normal, but we are not told if the projectile broke. It is implied, but not positively stated, that the plate was Harveyed.

It is most desirable that we should appreciate the results achieved, and, if possible, test these projectiles in England. We are told that the shells are not liable to spontaneous fracture; this should be tested in this country, for it has been seriously questioned. We have, at all events, one picked sample of Wheeler shot, a 6in. recovered projectile presented by Captain Jaques to our United Service Institution. Colonel Bainbridge has an experimental 6in. recovered shell made in the Royal Laboratory. The Wheeler has passed through a 7in. steel plate; the Woolwich one has passed through a 9in. steel plate. Both appear to be uninjured. We ought to test these two, and we trust that the test might lead to further competition. We all need to test foreign shot. Our own projectiles have been often very second-rate; Krupp's shot, used in his late remarkable trials, we think show evidence of being soft. Surely, since our ships will be attacked by foreign shot, and our own shot will attack foreign plates, we ought to try how our own plates resist foreign shot, and then we could judge by comparison the excellence of our own shot, and further the results of foreign plate trials would be correctly estimated by us if we knew the exact powers of the shot. At present we are too apt to use only our own plates and our own shot, and in England, America, and on the Continent, have fallen into mistakes in consequences.

BREECH MECHANISM OF THE U.S. 13IN. BREECH-LOADING GUN.

We described, in a paper which appeared in The Engineer, upon the commerce destroyer Columbia, the breech gear and other details belonging to the 8in. rifled breech-loading gun mounted in that vessel, commending the simplicity of the mechanism by which the breech screw is revolved for one-sixth of a turn, withdrawn from its position within the breech, and subsequently hinged away to the right or left, as wanted, upon the "carrier"—all operations being performed by so many turns of a winch handle.

The same system has been applied to the United States 13in. breech-loading guns, which comprise the main armament for their new battleships, but still further economy of parts has been observed in the design of the system by which the breech opening and closing movement is effected. Instead of the employment of two spindles and six or seven gearing wheels, as fitted to the earliest Canet guns of large calibre—which system, in a modified form, was adopted by the United States—the working mechanism of the "breech-plug," as the breech-screw is termed in America, is now actuated by a single spindle, which is contained within the metal of the gun itself, having two gearing wheels, as may be seen in the engraving, one of which is acted upon by the winch, and the other turns, runs out, and hinges away the carrier. The weight of the mushroom and breech-block combined is, in proportion, much lighter than in the earlier designs. There are also four sections of the interrupted screw on the plug and in the breech-box, instead of three as heretofore. Although this is such a heavy piece of ordnance, it requires under service conditions only two men on the crank handle to open or close, the breech being closed with nine turns, and locked with nine turns of the crank handle, eighteen turns altogether, independently of the hingeing away of the carrier.



BREECH MECHANISM OF THE U.S. 13in. GUN

An engraving is given of this breech mechanism, taken from a photograph, published in the "Proceedings" of the United States Naval Institute. It shows the plan for the movement of the opening and unlocking gear so admirably that we have thought it worthy of reproduction. No drawing has as yet been published of the analogous gear which is employed for the opening and closing of the breech-block, by hand, of the 12in. wire guns in the barbettes of the Majestic and Magnificent. But from a personal inspection of the breech mechanism in the British guns, and actual working of the gear, we are inclined to think that the American system has advantages. The securing of the revolving spindle and its gearing wheels within the actual mass of the gun's breech is a good idea.

The working of the winch and spindle can almost be learned from the engraving, without descriptive matter. But it may be briefly remarked that the flat-pitched thread of the lowest gearing wheel is—in the drawing—just about to engage with the diagonal thread seen in the slot on the breech plug. When, by engaging with this, it has forced the plug home to its seating, it is no longer controlled by the edges of the slot cut in the plug, so endeavours to work round the toothed edge of plug-face, and in doing so gives the necessary eighth of a turn to the breech plug. Precisely the same action is accomplished in the design of the breech gear for the guns of the Magnificent, but there is a greater complexity of parts. The way in which the final turns of the winch handle brings away the carrier, in the American gun, is too obvious to require any explanation.

The 13in. breech-loading United States gun is loaded with an ordinary hydraulic sectional rammer, and the recoil is controlled by an hydraulic cylinder, the running in and out being accomplished by independent hydraulic motors. The recoil of the gun during experiments was nearly the same in each round, varying between 47in. and 47½in., the full recoil allowed by the design being 52in. The dimensions, &c., of the gun are as follows:—Length, 40ft.; calibre, 13in.; weight, 60·5 tons; weight of projectile, 1100 lb.; weight of service charge, 550 lb.; muzzle velocity, 2100 foot-seconds; muzzle energy, 33,627 foot tons; perforation of wrought iron at muzzle, 34·6in.

THE IRON AND STEEL INSTITUTE.

The proceedings on the second day of the meeting were commenced with the reading of a paper by Baron Jüptner von Jonstorff "On the Introduction of Standard Methods of Analysis." This paper, communicated in reply to an invitation by the Council, is a review of the causes likely to produce differences in the results obtained by analytical chemists, and the methods proposed for obtaining uniformity in determination. The subject has for some time been under the consideration of chemists engaged in analytical work for iron and steel manufacturers, and it formed a principal topic at the International Congress on the testing of materials, held in Zurich last autumn, as well as having been under investigation for several years by commissions of an international character, working independently in America, Germany, Sweden, and the United Kingdom, whose results, notwithstanding the greatest care taken in performing the analytical work, show differences which, although they may for many technical purposes be disregarded, are sufficiently appreciable to have a disturbing influence on others, and as this is the case with work done with all precaution to ensure complete accuracy, it is evident that large differences may be expected from the current practice of working laboratories, where more summary methods must necessarily be employed.

Regarded from a general point of view, the sources of error in chemical analysis are:—(1) Gross errors in the analysis. (2) Impure reagents. (3) Errors due to the apparatus, &c. (4) Errors due to the operations. (5) Errors due to the analytical methods. (6) Personal errors. (7) Errors due to the differences in the calculation of the analyses caused by the values of the atomic weights on which they are based. (8) Want of homogeneity of the sample.

These various sources of error are noticed in detail by the author, who makes many valuable suggestions, which, however, are of too special a character to be given here. It will be evident, however, that some of those, notably Nos. 1, 2, and 7, are wholly, and Nos. 3, 4, and 5 partially, avoidable, while Nos. 6 and 8 are probably beyond remedy. The last point especially is of extreme importance, and, therefore, the author's suggestion that in most cases it is better to make determinations upon a number of separate samples and to compute the average result; rather than to sample from a number of points, mix the samples and make a single determination upon the mixture is commendable; although in many instances it may appear to be only a counsel of perfection.

A proposal for a new International Commission upon the subjects referred to in the paper was made by Dr. Wedding and the author, and adopted at the Zurich Conference. The principal object proposed seems to be an entirely laudable one, namely, a complete comparative study of all the more important methods of determining the constituents of iron and steel materials, taking into consideration possible sources of error. We may then either be satisfied with this comparison, or pass on to the setting up of standard methods. Such methods are, however, not to be prescribed for use at all times, but, on the contrary, it must be left to every chemist to work as he thinks best. Our aim must be to arrange as many different methods as possible, and to ascertain their relative conditions of value.

The proposals indicated by the author in this paper were generally well received by the chemists present, notably, by Mr. Snelus and Mr. Stead. Dr. Wedding gave an outline of the scheme proposed for working out the idea contained in the paper, which consisted of the formation of an international association of chemists, who were to divide the work among them, *e.g.*, one taking phosphorus, another sulphur, and so on, and after collating all the literature upon each subject, working it out experimentally. This work would, of course, be honorary except in so far as analytical assistance became necessary, which must be paid. It was thought that the latter work could best be done in a central laboratory, and for this purpose Zürich was admirably well suited. The annual cost would probably be about £3000, which could be met by 300 of the large ironworks in the world, each subscribing £10 per annum, the direction of the work to be under the author of the paper.

A member advocated the formation of special chemical libraries in the principal ironmaking centres, and Mr. Ainsworth thought that the Institute might devote part of its surplus income to an investigation of the kind. This latter proposition met with support from the chairman, who considered that part of the accumulated funds might well be expended upon immediate benefits.

Mr. Roberts-Austen then brought forward an account of some experiments upon the rate of diffusion of carbon, which, when stripped of much irrelevant matter, seemed to show that if a piece of iron is carburised from one end by cementation, the proportion of carbon in the metal diminishes with the distance from the contact of the two substances. A curve constructed from the numerical results obtained during the carburising of a steel rail by the Harvey process was exhibited in illustration, as well as two drawings of the concentration of copper by kernel roasting in pieces of pyrites, which did not seem to have much bearing on the matter under description. Mr. Osmond had, the author stated, succeeded in carburising electrotype iron with a diamond.

The next paper was that by Mr. J. H. Darby, of Brymbo, "On the Application of Mond Producer Gas to the Manufacture of Steel." This form of producer, which was originally designed for saving the ammonia contained in fuel gas produced from bituminous coal, is a very considerable departure from the usual practice, the gas being loaded with a large quantity of water vapour, added of design, to carry away the ammonia and protect it by lowering the temperature of the issuing gas, the steam so used amounting to 2¼ tons for every ton of coal gasified. By this means a proportion of more than 70 per cent. of the nitrogen contained in the coal may be recovered in the form of sulphate of ammonia, or nearly 100 lb. of that salt per ton of coal. This is done by carrying the gas through a series of up-and-down jacketed pipes, which are cooled by a mixture of air and steam intended for the grate supply of the producer, moving in the opposite direction to the gas, the heat absorbed being retained by casing the jackets with non-conducting covers. From these pipes the gas then passes into a rectangular cooler partly filled with water, which being churned into a fine spray by revolving beaters, precipitates all suspended matter, besides cooling it to 100 degrees. The next element in the combination is a lead-lined scrubber, filled with perforated bricks, where the ammonia is absorbed by dilute sulphuric acid in a 38 per cent. solution of sulphate of ammonia. After clarifying, the clear liquid is evaporated in pans heated by steam coils supplied continuously until the contents are boiled down to a thick mass, which when drained gives a fair quality of sulphate with the required strength of 24 per cent. of ammonia, which is readily saleable. The mother liquor containing free acid is pumped back to the scrubber. The gas on entering contains only 0·13 per cent. by volume of ammonia, but only about one-tenth of that quantity escapes condensation. No water is, however, deposited, as the quantity present is not sufficient to saturate the gas at the issuing temperature, namely, 80 deg. In a second scrubber filled with blocks of wood the water vapour is condensed by injection of cold water; the dried gas, cooled down to 50 deg., passes to the service main. The condensing water, which is raised to 78 deg., is cooled in a third scrubber by a current of air from a blower which becomes heated to about 74 deg. and saturated with water vapour, in which state it is forced on to the producer. The same water is constantly used for condensing the steam in one scrubber, and giving it up to the air in the other, so that about one-half of the steam required in the producer is recovered and returned to it, the remainder being furnished by the exhaust steam from the engines driving the blowers and pumps.

The gas producers are of a peculiar form, 21ft. high and 10ft. in diameter, which are fed in such a manner that the products of distillation of the coal are made to pass downward through the hot fuel, where the tarry substances are permanently gasified. The primary air is finally heated by passing through a jacket space in the casing of the converter. From 20 tons to 22 tons of coal are gasified in twenty-four hours, the ash of the fuel being deposited in the water tub of the ashpit in an unclinkered condition and almost entirely free from carbon.

The gas obtained in a dry state on an average contains:

	Per cent. by volume.
Carbonic anhydride	17·1
Carbonic oxide	11·0
Olefines	0·4
Methane	1·8
Hydrogen	27·2
Nitrogen	42·5
	100·00

Total combustible gas 40·4, giving about 1350 K.C. Cals. as determined by a calorimeter, per m³.

At 50 deg. the gas contains about 111 grams of water vapour—per metre cube measured dry—and this amount of moisture is no apparent drawback in the steel furnace.

Owing to the general belief that washed gas was not satisfactory in the manufacture of steel, Dr. Mond, by the author's advice, determined to put down a small steel furnace to demonstrate whether his gas would work satisfactorily and give the high temperatures required quickly and sufficiently. During the latter portion of 1895 a regenerative furnace was erected at the Winnington Works of Messrs. Brunner, Mond and Co. It was a three-ton furnace, and measured 12ft. between the blocks. The best performance was a complete charge in 7 hrs. 35 min., thus working rather faster than three charges per day of twenty-four hours. No hitch of any kind occurred in working this furnace, nor did any trouble develope itself with the washed gas. The steel made contained from 0·14 to 0·45 per cent. of carbon, 50 per cent. containing under 0·2 per cent. of carbon.

The average complete analysis of nine casts gave the following results:—

	Per cent.
Carbon	0·240
Silicon	0·038
Sulphur	0·039
Phosphorus	0·037
Manganese	0·457

The mechanical test of twelve samples of the steel containing from 0·16 to 0·22 per cent. of carbon gave the following results:—

Cast. No.	Carbon per cent.	Diameter, inches.	Breaking strain per sq. in. tons.	Elongation in 8in., per cent.	Percentage of contraction of area.	Limit of elasticity per sq. in. tons.
20/1	0·17	1·14	25·6	35	50	16·4
2	...	,,	25·5	32	51	16·4
25/1	0·22	,,	25·8	35	53	16·6
2	...	,,	27·6	32	53	17·0
30/1	0·16	,,	25·8	36	53	16·4
2	...	,,	25·8	33	53	15·9
35/1	0·16	,,	25·4	33	56	16·7
2	...	,,	25·2	35	56	16·1
40/1	0·18	,,	27·3	32·5	53	17·6
2	...	,,	27·1	33	53	17·3
41/1	0·17	,,	26·2	35	53	17·1
2	...	,,	26·3	34	51	17·4

There were no skulls in the ladle from the beginning to the end of the experiment, the metal always being hot and settling quietly in the moulds. During the experiment forty-one charges were converted into steel. Average time: charging, 18 min.; melting, 3 hrs. 9 min.; working, 5 hrs. 39 min. Average duration of charge, 9 hrs. 6 min. Shortest time taken, including charging and repairs, 7 hrs. 35 min. Total make of steel, 99 tons 3 cwt. Yield on the metals charged, 95·33 per cent.

Description.	Weight of materials charged.				Used per ton of steel.
	Tons.	Cwt.	Qrs.	Lbs.	
Hematite pig iron	79	10	3	0	16·04 cwt.
Steel scrap	23	12	3	0	4·77 cwt.
Ferro-manganese	0	16	2	2	18·7 lb.
Iron ore	16	10	0	0	3·39 cwt.

The measurements as to the quantity of gas used have been given; but as the furnace was drawing its supply from the works mains, it is difficult to arrive at this accurately. The author would prefer to let the question of consumption rest by saying that three charges of steel were made in twenty-four hours, and that the amount of gas consumed by the furnace was not appreciable at the gas-producer. The experiments show conclusively that gas of the composition given is entirely satisfactory for the manufacture of the softest kinds of steel, and that it does not contaminate the metal with sulphur. From the following analysis it will be seen, that the constitution of the gas is considerably modified by the action of the generator, as shown by Table A in the next column.

These analyses are averages of the results obtained by two separate chemists, and agree within the limit of experimental error.

In illustration of the latter analyses some figures were produced by Mr. Bauerman, who showed that the change indicated was an evidence of a reversal of the action of the producer by the regenerator, *i.e.*, carbonic acid was partially reduced by hydrogen with the production of carbonic oxide and water vapour, a reaction which he believed had not been previously recorded as such. The figures seemed to correspond to a reduction of about one-third of an equivalent of carbon dioxide with a consumption of 0·66 per cent. of hydrogen. Mr. Snelus gave an account of the working of the furnace which he had examined at the author's invitation. Mr. James Riley went into the different trials that had been made of saving ammonia from producer gases but was not very sanguine as to the profit to be realised upon the large cost of the plant. Mr. Paul, in a most interesting speech, went into the chemistry of the subject, and gave some figures as to the actual decomposition of carbon dioxide by hydrogen which corroborate the statement in the paper. The discussion was summed up by Dr. Ludwig Mond, who dealt with the points raised by the different speakers in a manner that made it unnecessary for the author to add anything more in reply.

TABLE A.

	Mond Gas. No. 1. Before regenerator.	No. 2. After regenerator.
Carbonic anhydride	17·8	10·5
Carbonic oxide	10·5	21·6
Ethylene	0·7	0·4
Methane	2·6	2·0
Hydrogen	24·8	17·7
Nitrogen	43·6	47·8
	100·0	100·0
Calorific value	1430	1444

With the termination of this discussion the interest of the audience diminished, and the remaining business, which consisted in the discussion of Mr. Howe's paper, adjourned from the Birmingham meeting, and of sundry communications based upon it, was conducted before a very attenuated body of members, and such remarks as were made by Mr. Hadfield and Professor Arnold were mainly adverse to the position taken by the writer. It was somewhat unfortunate no supporters of the "allotropic" hypothesis were present, but we suppose that their absence may be taken as evidence that the controversy is no longer of any particular interest, in this country at any rate. A long paper by Mr. J. S. de Benneville "On the Study of Alloys with Iron Carbides, mostly of Manganese and Tungsten," was taken as read, as no one apparently was able to give an intelligible account of it in a small compass. This terminated the business, when, after the customary vote of thanks, the meeting adjourned, to reassemble at Bilbao in September next.

INSTITUTION OF CIVIL ENGINEERS OF IRELAND.

LIGHT OR SECONDARY RAILWAYS.

ON the 6th May, 1896, Mr. Alfred D. Price, M. Inst. C.E., read a paper on "The Location, Construction, and Equipment of Light or Secondary Railways," of which we give an abstract.

There has been considerable misunderstanding as to the term light railway, so that the author commenced by defining it, as applying to a "secondary line, whether of the broad or narrow gauge, which is laid out, and constructed, on economical basis, to meet the requirements of a light traffic to be conveyed at moderate speeds."

He proceeded to show the importance of railways as the main channels of circulation between man and man, and that upon their progress and efficiency depends in a great measure the vitality of a nation—just as life in the animal, the plant, and even the firmament itself, is dependent upon the natural law of circulation, in the blood, the sap, and the water. He pointed out that Ireland has not the centres of consumption arising from manufactures which in England and Scotland have enhanced the value of the more remote regions, but that our outlying congested districts are dependent on the carriage of their produce to great distances, for which, if there are no facilities, the real value of the produce is depreciated from having neither local demand nor means of transit; it therefore appears that a fully extended cheap carrying system is peculiarly necessary for this country. He drew a comparison between our old railway system and that of a tree—if nature could produce such—on which the branches are as heavy and strong as the trunk, or, a river, the tributaries of which were as large as its debouchment.

Having quoted several Acts of Parliament—from 1868 to 1889—authorising the construction of light railways, he went on to give his experience and typical examples of different systems—branches of the Great Southern and Western Railway—to Castleisland, to Mitchelstown, to Valencia, and to Kenmare; the 3ft. gauge railways of County Antrim and of County Donegal, and steam tramways, or railways partly on the margins of the public roads and partly upon land acquired for the purpose. Details of cost per mile were given and the effects of gradients and curves.

In conclusion, Mr. Price advocated the construction of economical extensions and branches as feeders to the trunk lines—these extensions to be adapted for the working of the ordinary goods wagons of the parent lines, with specially constructed passenger corridor cars, with end doors and central buffers, to be worked by light bogie locomotives at moderate speeds. Under certain favourable circumstances the public roads should be availed of. Frequent stopping places should be provided to give passengers the opportunity for alighting or for joining the train. No platforms would be necessary, and no buildings except where required for goods.

In this agricultural country the value of land adjacent to a railway is much enhanced, upon which fact the author advocated the principle of guarantees upon the lands so affected, as against the method of baronial guarantees at present in force.

The question of State aid and control was touched upon. It was advocated that the State should guarantee 3 per cent. upon sufficient capital to construct and equip the lines, and that a rate should be levied upon property improved in value, whether in lands or existing railways, provision being made for a rebate according as the undertaking paid anything more than its working expenses, so that there should be a local interest in the efficient working of the line and development of traffic.

State aid in the form of grants or loans implied State control—which should commence at the very initiation of the scheme—in determining the route, location, &c., and should be continued all through the construction, with a permanent control after completion, to insure that the line is maintained and worked for the convenience of the public, the development of the natural resources of the country, and the encouragement of industry amongst its inhabitants, which are the main objects aimed at by such expenditure of the public funds.

RAILWAY MATTERS.

The Najibabad-Kotdwara Railway has been opened for traffic.

The final inspection of the new railroad from Connah's Quay to Bidston by Colonel Yorke, for the Board of Trade, took place on Monday. This is the line that Mr. Gladstone traversed a few weeks ago. The line will be opened for passenger traffic next Monday.

Travellers to Newcastle will have noticed at the north end of the High Level Bridge one of Stevenson's earliest locomotives. It was known as "Puffing Billy," and has been deteriorating owing to exposure to the weather. The North-Eastern Railway Company has decided to place this relic in the interior of the Central Station, just as No. 1 Locomotive is preserved on the platform of Darlington Station.

Messrs. Killick, Nixon, and Co., Bombay, have been granted the concession for the Ahmedabad-Parantij Railway. This railway will be on the standard gauge, 161 miles long, and is estimated to cost, without rolling stock, Rs. 1,42,84,830, or Rs. 88,726 per mile, taking exchange at 13 pence the rupee. The project embraces also an extension of the line from Amalnar to join the Great Indian Peninsula Railway at Jalgaon. Whether this extension also will be thrown into the concession granted to the Bombay firm will, *Indian Engineering* says, depend upon the result of certain negotiations now pending with the Great Indian Peninsula Railway Company.

A serious railway accident took place on the 11th inst. in Algeria. A special train conveying from Mostaganem to Algiers 140 Algerian riflemen, destined for Madagascar, ran into a passenger train from Algiers at the entrance to a tunnel near Adelia station. The collision was so violent that both engines were wrecked. The night was dark, with rain falling, and the military train was descending an incline. The line is a single one, and there is as yet no explanation of the simultaneous presence of the two trains. Out of ten officers, who were in a first-class carriage next the engine, six were killed and three injured. Forty privates and the engine driver and fireman were also injured. The passengers in the other train were merely shaken. The injured were at once cared for by the French colonists in the neighbourhood, and they will be conveyed to the nearest military hospital.

In a report on the collision that occurred on the 11th March, at Bellahouston, on the Glasgow and South-Western Railway, Colonel H. A. Yorke says:—"Some three hours' shunting has to take place every night at this place—two trains of thirty-three wagons each having to be marshalled there—and there is not a single lamp in the yard. In my judgment it is not fair to the men or beneficial to the company to expect such work as this to be performed in absolute darkness. The accidents, fatal or otherwise, to men engaged in shunting operations still far exceed in number those incurred by other classes of railway servants, and no precaution should be omitted which would tend to increase the safety of these men. And it seems probable that the shunting operations would be carried on more quickly and with less likelihood of damage to rolling stock and goods, such as occurred on the occasion referred to, if goods yards were properly lighted."

It is not often that the cause of an accident is so clear as in that which occurred, on March 20th, at St. Blazey Station, on the Cornwall Minerals Railway—worked by the Great Western Railway. In this case, when the 12.56 p.m. passenger train from Par to Fowey was being set back over the points at the north end of St. Blazey Station, in the trailing direction, the two leading coaches left the rails. One passenger is reported to have complained of slight injuries. In concluding a report on this accident, Lieut.-Colonel G. W. Addison says:—"Signalman Prideaux admits that, as the Fowey train was being pushed back to the north end of the station loop, he reversed the loop points too soon, *i.e.*, before the train had passed over the points, and thus caused the derailment of the carriages. His only excuse is that he was very much hurried, as people were waiting at Middleway level-crossing, and clamouring for him to come out to open the gates, then closed across the road." Poor "worrited" Prideaux; but why send a Board of Trade soldier to Blazey's station to inquire into such a paltry affair?

On the 7th inst., a Committee of the House of Commons, presided over by Sir Mark Stewart, had before them a Bill promoted by the Corporation of Sheffield, seeking to repeal the restriction imposed by a local Act of 1872 upon their working the tramway constructed by them. This repeal was strenuously opposed by a company who, as lessees of the Sheffield Corporation, at present work the city tramways, and are themselves promoting a Bill to substitute mechanical for animal haulage, and for other purposes. The two Bills were taken together, the Committee being only authorised to consider the Corporation Bill by a resolution of the House, passed, after some opposition, on Monday, to suspend Standing Order 171. Witnesses on both sides spoke to the results of municipal tramway working at Glasgow, Leeds, Huddersfield, Plymouth, and other places, and there was also frequent reference in argument and evidence to the new powers proposed to be given to municipal bodies, county and district councils, by the Light Railways Bill now pending. After a three days' hearing the Committee unanimously passed the preamble of the Corporation Bill, and limited the company's Bill to one for their winding up voluntarily, but accompanied by an undertaking from the Corporation to buy up the company's cars, horses, and equipment, in addition to their fixed plant, at the expiration of their lease next July. Mr. Clifford, Q.C., appeared for the Corporation of Sheffield; Mr. Balfour Browne, Q.C., and Mr. Lewis Coward for the company. As the first case of this nature heard and decided since Standing Order 171 was suspended, the proceedings and finding of the Committee excited much interest among tramway authorities, private and municipal.

In a report on a collision which occurred on the 18th of February at London Bridge station, on the South-Eastern Railway, Major Marindin says:—"As to the cause of this collision, which narrowly escaped being a very serious one, there is no doubt whatever. The 5.30 p.m. down North Kent train arrived at London Bridge station at 5.45 p.m., and stopped on No. 5 line at a point about 84 yards short of the end of the platform. After the station work was completed, the driver received the usual signal from his guard that the train was ready to start, and having, as he believed, seen that the signals were off for No. 5 line, he put on steam and started steadily. When the train had run for about 80 yards the front guard of the train on looking at the signals, then close by, saw that the signals for No. 5 line were at danger, and those for No. 6 line, the actual junction with which was only 66 yards ahead, were off, and he at once applied the continuous brake and shouted to his driver, who then for the first time perceived that he was running against signals. He at once shut off steam, but before the train could be brought to a stand the engine had reached the fouling point of the junction of Nos. 5 and 6 lines, and was struck by the second or third vehicle in the down Ostend mail, which had entered the station on No. 6 line at about the same time that the North Kent train started, or very soon after, and was running with all signals off for it, at a speed probably of about twenty-five miles an hour. It is a matter for the company to consider whether a platform inspector or a guard should not be instructed to see that the fixed signal is off before he gives the driver a signal that the train is ready to start. This is the rule upon some lines, and although a guard's signal should never be taken by a driver as a signal to start unless he himself sees that the fixed signal is off, it seems to me that it would tend to prevent such accidents as the one under consideration if the rule were general, although I am aware that there are reasons of some weight against it."

NOTES AND MEMORANDA.

In Greater London 3671 births and 1948 deaths were registered last week, corresponding to annual rates of 33·1 and 16·5 per 1000 of the estimated population.

The deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 18·5 per 1000 of their aggregate population.

Piles from 100ft. to 105ft. long are being used by the Tacoma Land Company, of Tacoma, Washington, in replacing a portion of its sea wall with a pile and stringer wharf. The water is 30ft. deep and the outer row of piles range from 100ft. to 105ft. in length, 10in. diameter at the tip and 22in. at the butt. The piles are made from the "Washington Fir"—the Douglass Pine—and from the same timber, a few piles were cut and recently used, 120ft. long and 24in. at the butt. Sticks 90ft. long, three-car lengths, in squared timber are often shipped East; and, *Engineering News* says, it is expected that changes in the alignment of the railway will soon permit the shipping of 100ft. lengths.

Lord Rayleigh, in a communication to *Nature*, contributed the following on the chemical position of argon. The gas was prepared from atmospheric air with the aid of oxygen and alkali only:—"Weighings at 0 deg. C. upon a large scale—two litres—and with the apparatus formerly employed for other gases, give, as the density of argon, $(O_2 = 16)$ 19·940, a number in almost exact agreement with that obtained by Professor Ramsay, working upon a relatively small scale, and with gas derived by magnesium. In spite of its greater density, the refraction $(\mu - 1)$ of argon is only ·961 of that of air; so that if we take for air under standard conditions $\mu = 1{\cdot}0002923$, then for argon $\mu = 1{\cdot}000281$."

"There is, perhaps, no country in the world where art, science, and industry, are so much encouraged by the awarding of prizes for meritorious work and progress as in France; and although it might possibly be argued that no invention or appliance of the first order of importance was ever the direct outcome of a prize competition, still it is not to be denied that the origin of many advances can be traced to the stimulus of a prize competition. Even," says the *Electrical Engineer*, "if such competitions do not always result directly in bringing out the desired improvement, they nevertheless draw attention prominently to the object in view, and set to work many who would otherwise remain passive, if not in total ignorance of the needs of the times."

An auxiliary assay balance has been described by Mr. Robert Law, F.I.C., applied to bullion assaying, the object of which is to give the weight of the gold "cornet" with sufficient accuracy to enable the assayer to put the correct weight in the pan of the ordinary assay balance, and to decide the remaining fractions by means of the rider alone. This auxiliary balance is of such dimensions as to be easily accommodated in the case of the ordinary assay balance. The advantages claimed are:—(1) Saving of time in weighing when gold of varying finenesses is under assay. (2) Reduction of the wear in the weights. (3) Increased life for the ordinary assay balance. (4) Avoidance of much of the concentrated attention which tends to make the assayer's work monotonous.

A recent paper in the *Comptes Rendus* described a self-registering thermometer balance, containing either gas or saturated vapour, by MM. H. Parenty and R. Bricard. The two arms of a balance carry respectively a barometer and an air thermometer, both dipping into the same mercury trough. At constant temperature, and with varying atmospheric pressures, the alterations in the weights of the two arms caused by the movements of the mercury are identical, and the balance remains in equilibrium; but an alteration of temperature causes a motion of the beam, which can easily be made self-registering. For a small range of temperature the sensitiveness of the apparatus is considerably increased by substituting a volatile liquid for the gas. The device also readily acts as a temperature regulator.

After making a number of experiments on the heat conducting power of iron and steel, Mr. W. Beglinger arrived at the following conclusions:—The results show that the heat conducting power of the different kinds of iron is altogether different. It is, therefore, of the greatest importance to know the coefficient of the inner heat conducting power. Steel and wrought iron show a more uniform conduct in this matter than cast iron. It is not confirmed that hardening reduces the conducting power of steel by almost one half, though it may be conceded that hardening will reduce it slightly. The difference in working, by forging or rolling, showed only in one case, with wrought iron, considerable differences for the conducting power, steel never. Casting seems to cause far more irregularities. Wrought iron showed generally better conducting power than steel.

According to statistics collected by the office of Road Inquiry of the United States Department of Agriculture, the amount of loss each year by bad roads of the country is almost beyond belief. Some 10,000 letters of inquiry were sent to intelligent and reliable farmers throughout the country, and returns were obtained from about 1200 counties, giving the average length of haul in miles from farms to markets and shipping points, the average weight of load hauled and the average length per ton for the whole length of haul. Summarised, it appears that the general average length of haul is twelve miles, the weight of load for two horses 2002 lb., and the average cost per ton per mile 25 cents, or 3 dols. for the entire load. Allowing conservative estimates for tonnage of all kinds carried over public roads, the aggregate expense of this transportation is figured at 946,414,600 dols. per annum. Those in a position to judge calculate that two-thirds of this, or nearly 631,000,000 dols., could be saved if the roads were in reasonably good condition. At 4000 dols. per mile a very good road can be constructed, and if an amount equalling the savings of one year were applied to improving highways, 157,000 miles of road in this country could be put in condition. The effect of this would be a permanent improvement, and not only would the farmer be astonished in the sudden reduction in his road tax, but he would also wonder at the remarkable falling off in the cost of transportation. Such a work ought to afford a good investment. He would also find that he required fewer horses and less feed for them.

Mr. Langhorne, writing to the *Times* concerning traffic on London and the Tower Bridges, quotes an article in "Knight's Year Book" for 1861, "Thames Embankments and Crowded Streets":—On London Bridge, in 1853, between 9 a.m. and 6 p.m., there crossed 63,080 pedestrians and 11,498 vehicles. In 1856 between 8 a.m. and 6 p.m., October 22nd, pedestrians not stated, 15,992 vehicles. In 1857—authority not stated—between 8 a.m. and 8 p.m, February 11th, 85,690 pedestrians, 14,890 vehicles. In 1859—Mr. Harvey—between 6 a.m., March 16th, and 6 a.m., March 17th, 107,074 pedestrians, 20,444 vehicles, or 4461 pedestrians and 850 vehicles per hour. In 1895—Bridge House Committee—between 6 a.m., September 20th, to 6 a.m., September 21st, 108,598 pedestrians, 21,646 vehicles, or 4522 pedestrians and 902 vehicles per hour. Between the same hours there passed over the Tower Bridge 25,255 pedestrians and 8751 vehicles, which may be taken to represent roughly the increase of traffic which would have passed over London Bridge on the day stated, had the Tower Bridge not been built. Adding the traffic of the two bridges together we have a total of 133,853 pedestrians and 30,397 vehicles, or at the rate of 5577 pedestrians and 1266 vehicles per hour. Comparing this with Mr. Harvey's figures in 1859, we find the 1895 returns in excess of the 1859, roughly, 1000 pedestrians and 400 odd vehicles per hour. Going back to Mr. Bennoch's figures for 1853, it seems fair to infer that the pedestrian traffic has more than doubled, and the vehicular probably trebled, in forty years.

MISCELLANEA.

The new United States battleship Massachusetts, on her trial trip, covered 62 knots in 3 hours 50 min. 23 sec., an average of 16·15 knots. The premium earned by the contractors amounts to 100,000 dols. The trip was entirely satisfactory, and shows that the battleship is the swiftest of her class.

The City and Guilds of London Institute is issuing advertisements inviting applications for the professorship of mechanical engineering and applied mathematics at the Technical College, Finsbury, rendered vacant by the appointment of Professor John Perry, D.Sc., F.R.S., to a professorship at the Royal College of Science.

The meeting and show of the Bath and West and Southern Counties Society is this year at St. Albans, commencing on Wednesday, the 27th May, and closing on the 1st of June. The list of implement exhibitors has been published, and a general programme, from which it appears that there will be working dairies in operation, with the usual attractions.

There is not much prospect, says the *Naval and Military Record*, that 1896 will witness the keel-plate of Devonport's first battleship in position. The slip from which the Arrogant will be launched on the 26th inst. requires so much alteration that the officials of the Works Department anticipate it will take until the end of the year before they are able to hand it over to the Chief Constructor.

At a meeting of arbitrators appointed under the South Staffordshire Mines Drainage Acts, held at Dudley on Wednesday, the solicitor to the Mortgagees' Committee called attention to the Commission's financial position, and said it would be disastrous to the district if the pumping engines had to stop. It was shown that, although the full parliamentary rate per ton of coal raised was 9d., yet that owing to trade depression, graduations had of late of necessity been freely allowed, the consequence being that the average rate for last year was less than 5½d. The tonnage of minerals on which rates were paid was also a decreasing quantity. The arbitrators, therefore, this week, have allowed graduations in as few cases as possible. It is, however, satisfactory to know that progress was reported with the Tipton new drainage scheme, which at a cost of £100,000 will unwater a large area, and greatly benefit the coal trade. The arbitrators made a draft award for the Tipton district.

Sir William H. White, Director of Naval Construction, will within the next few days pay a visit to the Clyde district, the inspection of the unfortunate cruiser Dido in the Clyde Trust's Graving Dock being the object of his visit. This vessel, it will be remembered, met with a serious mishap while being launched on the 17th of last month from the yard of the London and Glasgow Shipbuilding Company. Since being docked about twelve days ago it has been ascertained that the damage sustained has been more serious that at first supposed. Several strakes along the port bilge—on which she settled down after having swerved from the upright end from the line of ways—are indented for a considerable portion of her length, and even the line of inside framing has been damaged at parts. But for the wood sheathing with which the under-water portion of her hull was covered, the damage sustained would have been of a considerably more serious nature. As it is, the repairs will necessitate her being in dock for six weeks or so.

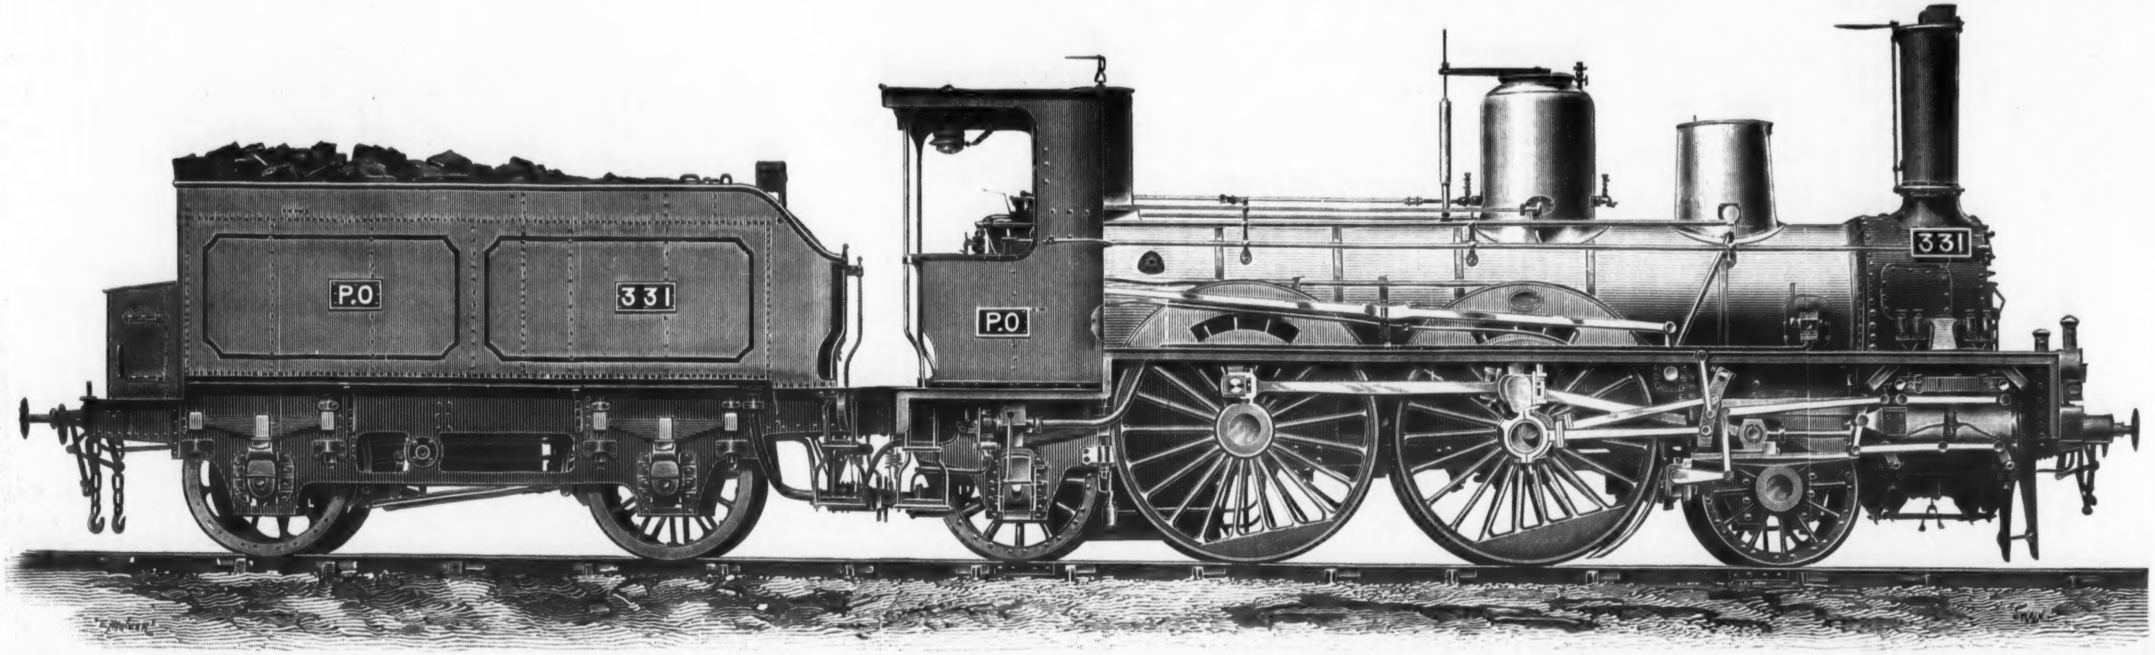
An experiment on a large scale is being made with the sewage of Exeter by means of what is called the "Septic Tank System" devised by Mr. F. J. Commin the Exeter City Surveyor. The plant, which was laid down in January last, and was filled on the 22nd of that month, and has been at work ever since, is situated close to the river Exe, near the main sewer from St. Leonard's, a part of the flow from which is dealt with by the system. The quantity handled is ordinarily 7500 gallons per day, which would represent the sewage of from 300 to 400 people. There is no "treatment" in the ordinary sense of the word. No chemicals or other ingredients are added to the sewage. The "Septic Tank" is 24ft. long by 9ft. 6in. wide, and from 3ft. 6in. to 4ft. deep, and is arched over and covered with earth. Its capacity is about 6000 gallons. During the progress of the sewage through this tank, which occupies some twenty hours, it is cut off from light and air. The tank is formed with inlet and outlet, arranged so that the upper portion of the contents are undisturbed. A sewage scum forms on the top, eventually reaching 3in. in thickness, and by this all soluble solids are thrown into solution by bacteriological action. The outflow from the tank is comparatively clear and odourless, and is considered quite fit for discharge into the sea or tidal water, or for filtration or for utilisation on land.

In connection with the launch by Messrs. William Denny and Bros., Dumbarton, on the 30th ult., of the twin-screw Channel steamer Sussex, for the Newhaven and Dieppe service, built to replace the ill-fated Seaford, lost last year, reference was made to the fact that the same builders have not only constructed several vessels for this route—the service indeed having been inaugurated many years ago by a vessel from their stocks—but they were pioneers of steam service generally across the Channel. In the year 1821 the first steam vessel which crossed from Calais to Dover was built by the grandfather of the present younger members of the firm, the late Mr. William Denny. This vessel was called the Rob Roy, and was only 90 tons burden, with engines by David Napier, of 30 horse-power. Her speed was not great, being something like seven to eight knots; but in rough weather she would do the passage in less time than the sailing boats then sailing; in fine weather with favourable winds, the sailing boats beat her. In sharp contrast to this old-time order of things is the performance of vessels like the Sussex and many others, which Messrs. Denny have been instrumental in providing for present-day service. The Sussex, fitted with forced draught on the closed stokehold principle, is intended like the Sleaford, which she replaces, to develope a speed of not less that 20 knots per hour on the Newhaven and Dieppe crossing.

The Bridges Committee of the London County Council have prepared a scheme, which will shortly be submitted to the Council for approval, for the construction of a tunnel under the Thames to connect Millwall with Greenwich. It is intended that the tunnel shall be for foot passenger traffic only, having a footway of 8ft., with a headway of 9ft. 4½in. in the centre reduced to a minimum of 7ft. 6in. at the outsides. The cast iron tubing would be lined inside with concrete faced with glazed tiles, and the tunnel would be lighted by electricity. The shafts on either side of the river would be 32ft. 8in. internal finished diameter, and a spiral staircase 6ft. wide would be constructed, 20ft. clear diameter being left in the middle, in which hydraulic lifts might be constructed at some future date, should necessity arise. The height of the stairway would be 43ft. 6in. on the north and 51ft. on the south side of the river. The total estimated cost of the works amounts to £65,000. The land which would be required would cost £5500, making a total for land and works of £70,500. In addition to that, as the law at present stands, £25,000 would have to be paid as compensation to persons interested in the existing ferry and ferry rights, but the committee hope the Council will succeed in obtaining a clause by which improvement of interest will be considered, thereby reducing this amount very considerably. The capital cost of the tunnel, including compensation for the ferry rights—viz., £95,500—has been reduced to an annual sum, and amounts to about £4190 per annum for the first year, diminishing each year till the debt is paid off in fifty-three years. The committee ask the Council to seek the necessary parliamentary powers to carry out this scheme, which they state will meet a long-desired requirement of the people living on both sides of the river

LOCOMOTIVE ENGINE WITH CORLISS VALVES, PARIS AND ORLEANS RAILWAY

M. E. POLONCEAU, ENGINEER



ECONOMICAL HIGH-POWER LOCOMOTIVES.

By James Dunlop.

With their engines pressed to their utmost limit of power and endurance, most locomotive superintendents will be inclined to doubt the possibility of the double adjective above being realised, experience having proved to them that the present construction of locomotive is much the reverse of economical when developing its extreme power. Limited in respect to the dimensions of the boiler, and consequently in the amount of steam at disposal, it is somewhat surprising to find no attempt has been made in this country to make the engines more economical in their use of the steam by improved construction of cylinders and valve gears capable of conforming to all the requirements of locomotive practice. There is, of course, the failure of numerous arrangements of expansion valves working on the back of the ordinary slide valve to point to as a reason for attempting nothing in this direction, but the reasons for these failures should be sufficient to point out the direction in which they may be remedied and made conducive to success. In the first place, such arrangements do nothing towards reducing the clearance spaces, but increase them rather. As a consequence a greater quantity of steam is lost each stroke than formerly, this loss being further increased by the reduced compression, which was intended to be an economical feature of the arrangements. In the second place, the live steam was still admitted by the ports and passages just cooled down by the previous exhaust; these passages being at a lower temperature than formerly, the initial condensation was also much increased, the lower temperature being due to the reduced compression. These reasons might also be used to show why locomotives, when moderately loaded, are as economical as they are in comparison with other classes of engines. This appears to be due to a balance that is struck between the amount of expansion obtained, and the proportion of the work of compression that is saved, the latter proportion being greatest when the time duration of compression is the least, a circumstance that explains all the various proposals to limit the compression as a fraction of the stroke.

A further objection, if not a reason, for the failure of these arrangements was the different handles required for their manipulation. The problem before locomotive superintendents whose engines are generally taxed to their utmost is, therefore, the restoration of the balance above mentioned. The first step towards this would be the reduction of the clearance spaces, and consequently of the losses due to clearance; the second, the separation of the admission and exhaust passages so as to reduce initial condensation; and the third, the use of a valve gear actuating independent admission and exhaust valves, so that the requisite amount of expansion and proportion of work of compression saved may be such as will bring about the desired balance.

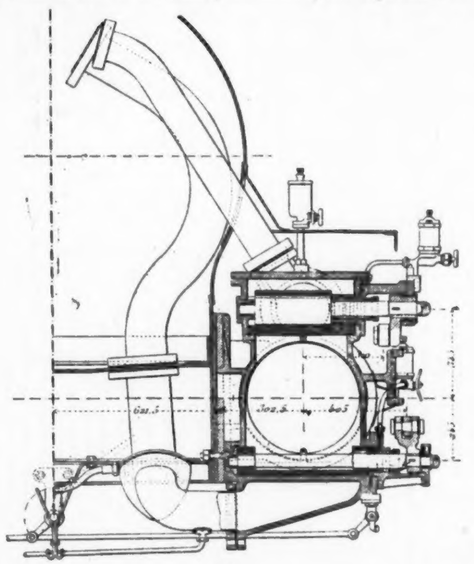


Fig. 3

On the Paris and Orleans Railway this has already been done by M. E. Polonceau on seventeen of his locomotives, and the result is that, while being 15 per cent. more economical in fuel compared with ordinary engines doing similar work, the power of these locomotives has been increased considerably. The accompanying illustration—Fig. 1—is that of one of the passenger engines, and it may be noticed the engine is fitted with Corliss valves, one at each corner of the cylinders. The two upper valves are for admission and the lower valves for exhaust, both sets of valves being actuated by a Gooch link motion, and all adjustments made by one reversing handle. The detail views—Figs. 2, 3, 4, and 5—show the construction of the cylinders, valves, and valve gear. The link motion has two excentrics and rods for forward running, and one excentric and rod only for backward running. This is for the double purpose of preserving the stresses in one direct line, and of providing an ample amount of surface for wear, there being no great necessity for unusual surfaces on the backward excentric, &c., as in France there are no double-ended suburban engines, and a Government regulation prohibits the use of an engine tender first. The link is of the box type, and is longer at the upper end than at the lower, for the purpose of accommodating an extra deep die block to which two radius rods are jointed one above the other, the lower radius rod being the one that is adjusted symmetrically on either side of the centre point—or suspension point—of the link, as in ordinary slide valve motions. The result is that the upper radius rod has an unsymmetrical adjustment range on either side of the suspension point of the link, a peculiarity of which the effect will be seen later on. This upper radius rod is jointed to a rocking lever, which is used simply to alter the direction of the movement transmitted by the link, and to make a convenient connection to the exhaust valve, levers, &c. The lower radius rod is coupled direct to the admission valve levers, and the motion transmitted to the admission valves is exactly the same, and has the same effect on the cut-off as an ordinary slide valve, according to the position of the die block in the link. The radius rod actuating the exhaust valves, owing to the unsymmetrical adjustment mentioned, will for one direction of running—the forward—cause the exhaust valves to move so as to effect release and compression at much later periods than those corresponding to the cut-off when compared with the periods given by an ordinary slide valve. In the other direction the opposite takes place. As a matter of fact, practically no expansion can be obtained in backward running, release and compression taking place immediately after cut-off. These results and a comparison with an ordinary slide valve gear are given in Table I.

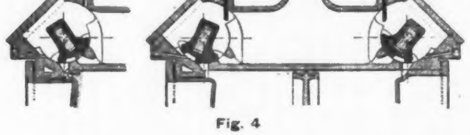

Fig. 4

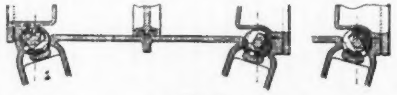

Fig. 5

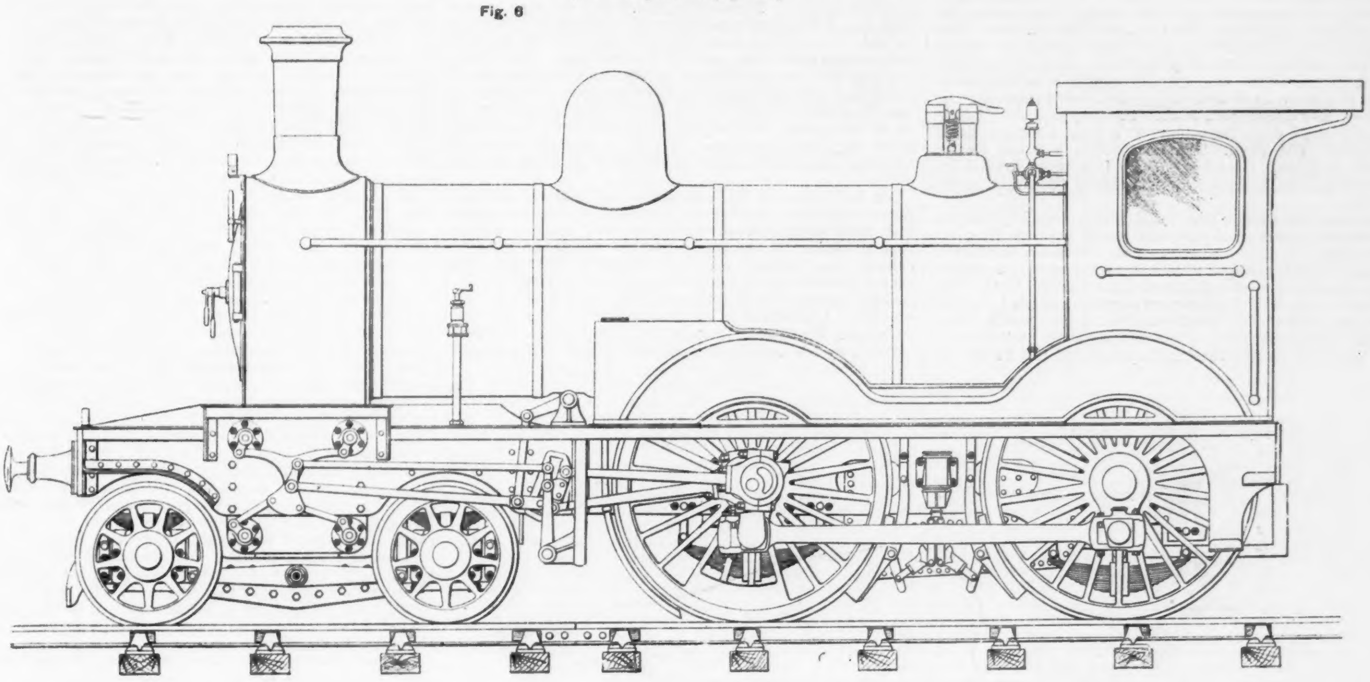
The construction of the admission valve is that known as the Trick, the exhaust valves being ordinary double-ported. As both constructions give a double opening at each end of the cylinders, no wiredrawing at early cut-offs or excessive back pressure is experienced, while the position of the exhaust valves is such as to ensure at all times the complete draining of the cylinders. The small amount of the clearance spaces will be appreciated, as will also the substantial nature of the construction throughout. The patentees of this gear are MM. Durant and Lewcauchez.

As in this country engines are generally required to work equally well in either direction, the arrangement illustrated in Fig. 6 was produced to meet these conditions, while giving all the economical results obtained in forward running by the arrangement just described. So far as the cylinders and valves are concerned, the construction is practically the same, with the exception of the exhaust valves, the latter being single ported, a circumstance that admits o a further diminution of the clearance spaces. The gear is

LOCOMOTIVE ENGINE WITH CORLISS VALVES, PARIS AND ORLEANS RAILWAY

(For description see page 490)

Fig. 6



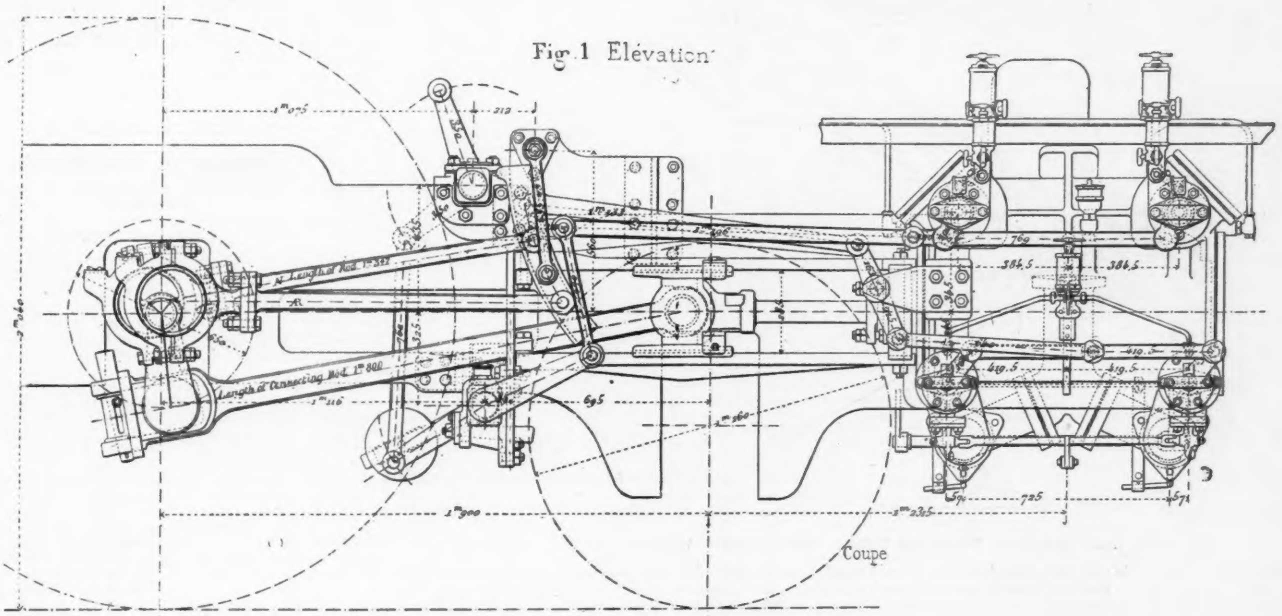


Fig. 1 Elévation

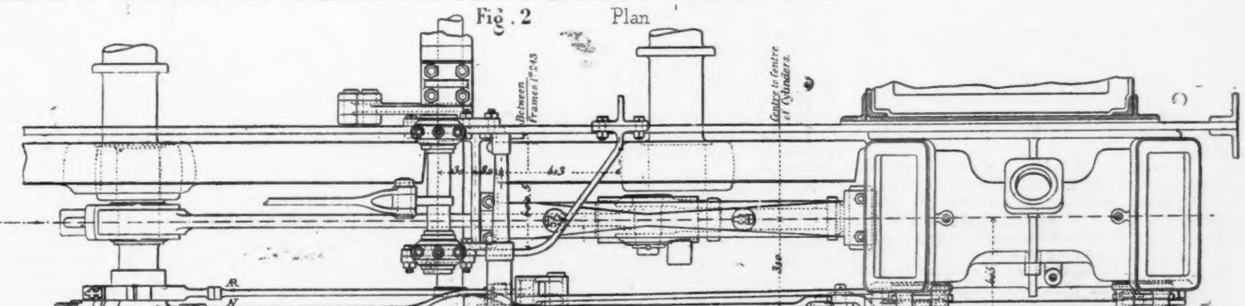
Fig. 2 Plan



a modified Gooch motion, having one radius rod only, which is jointed to a somewhat T-shaped piece coupling the admission valve levers. This coupling-piece carries at its lower centre a double-ended lever, the upper centre of which is coupled to a prolongation of the link-hanger, the lower centres of this lever being coupled to the exhaust valve levers by the links shown. By this arrangement the admission valves have exactly the same motion and effect on the cut-off as an ordinary slide valve, according to the position of the die block in the link. The motion of the exhaust valves is a compound of the variable motion of the admission valves, and the invariable motion of the link-hanger, which is in time with the motion of the piston, and it may be understood that this compound motion is the equivalent of that obtainable from a second radius rod placed some distance above or below the radius rod actuating the admission valves, according to whether this rod is in forward or backward gear. This makes the results of both backward and forward running alike, and causes the exhaust valves to be moving to effect release and compression at much later periods than those corresponding to the cut-off when compared with the periods given by an ordinary slide valve. These results and a comparison with an ordinary slide valve gear are given in Table II. The disposition of the pins at the bottom centres of the double-ended lever, and the lengths of the links coupling this lever to the exhaust valve levers, is such that a peculiar dwelling and active period is alternate imposed on the motion of the exhaust valves, this being the feature that admits of the use of single-ported exhaust valves with their attendant diminution of the clearance spaces. A further result is the reduction of wear during the dwelling periods. In addition to economical use of the steam, the use of Corliss valves has resulted in a much lessened wear of the parts of the link motion, this being due to the fact that Corliss valves require much less power to work them than ordinary slide valves do, Corliss valves being in equilibrium during the time the ports are open. Their construction also is an economical one, the greater part of the operations in machining consisting of plane turning and boring. Stuffing-boxes are used on the valve spindles of the Paris and Orleans engines, but these spindles may be constructed so as to require no stuffing-boxes, thus doing away with a source of considerable trouble; in fact, as a whole, the question of applying this type of cylinders and gear to locomotives in this country may be worthy the careful consideration of many of our locomotive superintendents at the present time. The arrangement illustrated in Fig. 6 is the invention of the writer.

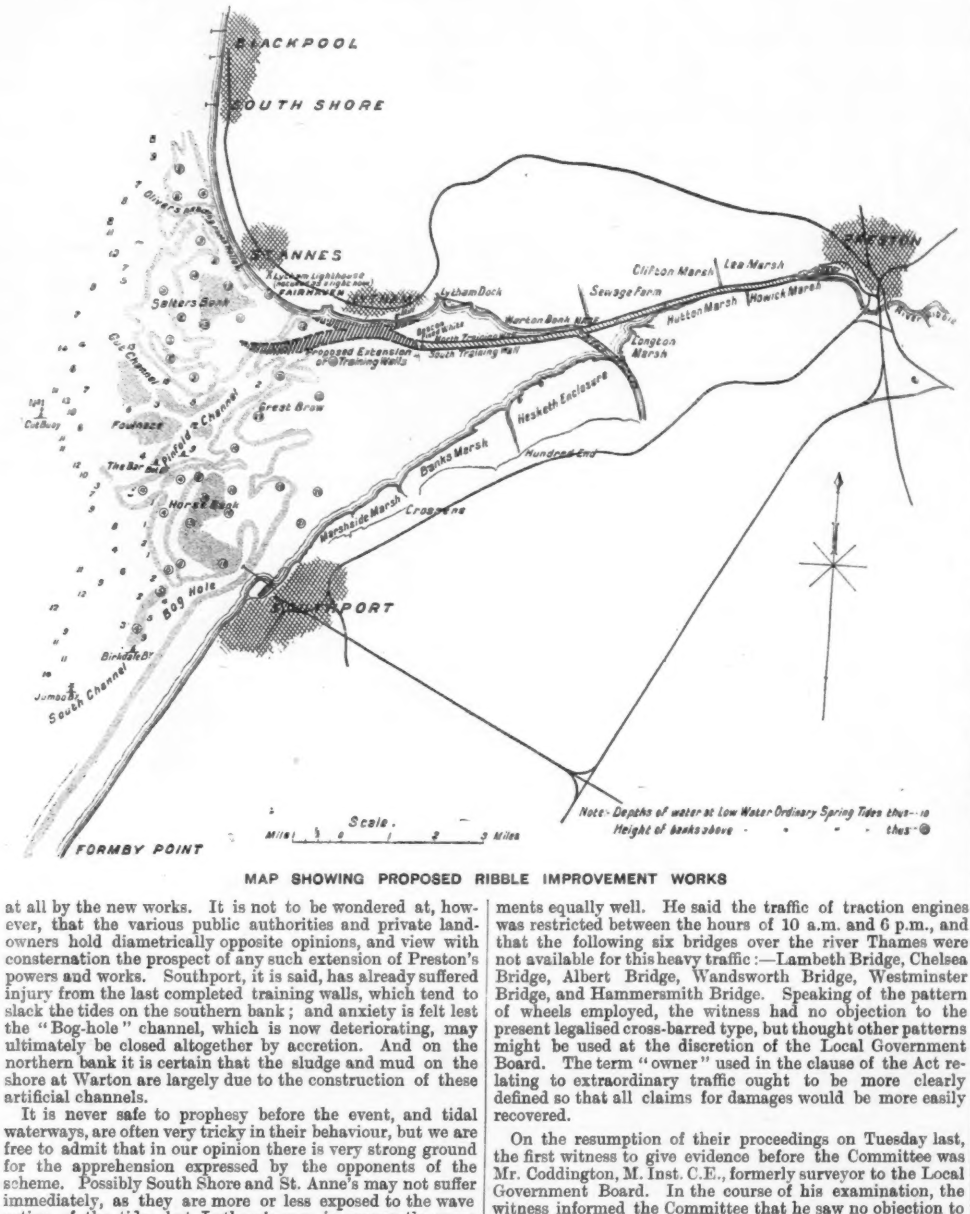
Backward and forward are alike.

PRESTON AND THE RIBBLE NAVIGATION.

The map which we publish to-day, showing the estuary of the river Ribble with its shoals and sand banks, and the training walls already constructed by the Corporation of Preston, is of special interest at the present time, as the Bill is now being considered by the Lords Committee. The Preston Corporation, having spent their ratepayers' money lavishly in constructing a dock below the town, are naturally anxious to secure the best possible approach to their basin. Since 1889 they have accordingly obtained powers for and have actually constructed double training walls about eight miles in length down the estuary to a point almost opposite to Lytham Old Dock. The Corporation now are seeking powers to extend these walls some four miles further out towards the Bar, and the above map shows the situation at a glance.

Although, in 1889, a firm belief was expressed by the promoters that their then proposals would be final, they now claim that, largely on account of an alteration in the Gut channel, they are obliged to seek further powers if a channel is to be secured to shipping bound for Preston Dock. The promoters and their witnesses are sanguine enough to suggest that the foreshore of Lytham and St. Anne's would be improved by the extension of the existing walls as indicated; and they also declare that Southport would not be affected at all by the new works. It is not to be wondered at, however, that the various public authorities and private landowners hold diametrically opposite opinions, and view with consternation the prospect of any such extension of Preston's powers and works. Southport, it is said, has already suffered injury from the last completed training walls, which tend to slack the tides on the southern bank; and anxiety is felt lest the "Bog-hole" channel, which is now deteriorating, may ultimately be closed altogether by accretion. And on the northern bank it is certain that the sludge and mud on the shore at Warton are largely due to the construction of these artificial channels.



MAP SHOWING PROPOSED RIBBLE IMPROVEMENT WORKS

It is never safe to prophesy before the event, and tidal waterways, are often very tricky in their behaviour, but we are free to admit that in our opinion there is very strong ground for the apprehension expressed by the opponents of the scheme. Possibly South Shore and St. Anne's may not suffer immediately, as they are more or less exposed to the wave action of the tides, but Lytham's case is apparently more serious, and we shall watch with interest the fate of the present Bill.

Preston no doubt is entitled to consult her own special interest, but it must also be conceded that other authorities have an equal right to the natural action of the tides and waterway, and it may be possible to show that a course may be taken which will leave Southport in possession of the distant view of sea water which it has always enjoyed, with occasional inflows for temporary seaside boating, and yet allow Preston to improve the river and enable shipping of some importance to go to the large town now provided with docks.

TRACTION ENGINES ON ROADS.

On Thursday, the 7th inst., the first witness to give evidence before the Select Committee of the House of Commons was Mr. Cowan, M. Inst. C.E., county surveyor to County Down, Ireland. In this county there are 2500 miles of roads, of which about 400 miles may be classed as main roads. The cost of maintenance of these roads varies from £6 to £400 per mile per annum, according to the locality. The witness's experience of traction engine traffic was decidedly favourable to its more extended use across the channel, although the roads are chiefly poor. He gave an instance of an engine which had been running for two years, making two journeys per diem over the same road four miles in length without causing any damage. The road had previously been brought up to the required strength. The engine weighed 9¾ tons, and hauled loads varying between 6 and 15 tons, excluding the weight of the trucks. The latter were constructed with the rear axle longer by twice the width of the tires than the leading axle, so that the wheels broke gauge completely. It should be stated that the road is very hilly, one of the gradients having a rise of 1 in 12. The cost for maintenance per annum since this form of traffic has been in vogue has been at the rate of £64 per mile. Mr. Cowan said that they had no bye-laws for regulating traction engine traffic, and so far no complaints had been made, but considers that the imposition of a licence fee on these engines would be advantageous, while a plate giving the number of licence might be affixed on them. He saw no objection to an increase in the maximum limits of speed to three and five miles.

Mr. A. R. Binnie, M. Inst. C.E., chief engineer and surveyor to the County of London, was next examined, and stated that there were between thirty and forty traction engines licensed under this authority, and as far as he knew no damage was inflicted upon the roads by their use. The licence fee charged is £10 per annum, with a rebate of £5 if licensed in one other county, and £6 if licensed in two other counties. Questioned as to the imposition of a universal licence fee, Mr. Binnie thought the arrangement of rebates adopted by his County Council would answer the requirements equally well. He said the traffic of traction engines was restricted between the hours of 10 a.m. and 6 p.m., and that the following six bridges over the river Thames were not available for this heavy traffic:—Lambeth Bridge, Chelsea Bridge, Albert Bridge, Wandsworth Bridge, Westminster Bridge, and Hammersmith Bridge. Speaking of the pattern of wheels employed, the witness had no objection to the present legalised cross-barred type, but thought other patterns might be used at the discretion of the Local Government Board. The term "owner" used in the clause of the Act relating to extraordinary traffic ought to be more clearly defined so that all claims for damages would be more easily recovered.

On the resumption of their proceedings on Tuesday last, the first witness to give evidence before the Committee was Mr. Coddington, M. Inst. C.E., formerly surveyor to the Local Government Board. In the course of his examination, the witness informed the Committee that he saw no objection to raising the maximum limits of speed in towns and villages to three miles an hour, and on country roads to six miles an hour, except when passing up and down hills, when four miles would be a safe limit. Regarding the licence duties to be imposed on traction engines, Mr. Coddington considered that lighter types should be encouraged by the imposition of only a nominal fee. We understood the following scale to be that suggested:—Nine-ton engines, 10s. or 20s. per annum, but above this weight the rate to be increased by between £5 and £7 per ton, while the licensing authorities were also to be empowered to examine the engines before granting licences. The number of attendants to each engine should be kept as at present, but it should not be compulsory that one man should walk twenty yards in front of the engine. Mr. Coddington does not consider that the power to make bye-laws ought to be surrendered to a central authority, and would give power to road surveyors to obtain summary conviction of persons acting in contravention of the law with respect to the weights carried by trucks. Further, he thought it desirable that local bodies should be able to prohibit the use of traction engines on certain roads within their jurisdiction. This prohibition, however, was not to apply to agricultural engines. In case the owner of a traction engine wished to use such a road, he should give three months' notice of his purpose to do so, during which period the authority might consider the advisability or not of raising the standard to that of traction engines, any dispute to be settled by an appeal to the Local Government Board. The witness also considered the "extraordinary traffic" clause in its present form unworkable, and did not sufficiently protect the local authorities.

Mr. J. Cartwright, M. Inst. C.E., the surveyor for Bury, was the next witness called, and described the "exceptionally good roads" in his county borough. He stated that no licence fee was necessary for engines working in the district of Bury, but a deposit of £100 was demanded from the owner before his engine was allowed to traverse their roads. After the deposit is made a man is deputed to follow the engine, and take note of all damage done, the amount of which is deducted from the deposit before the latter is returned. This power would appear to have had the effect of almost preventing the use of traction engines in Bury, and it is to be hoped that with the anticipated legalising of wheels more suitable for sett-paved roads, the necessity for imposing such a severe restriction on the use of these engines will be obviated.

Mr. Aveling, of Messrs. Aveling and Porter, Rochester, said that with the improved differential speed gears which are now fitted by the best makers, the maximum limit of speed on country roads might safely be increased to six miles instead of four miles, while a speed of three miles an hour in towns would render traction engines less obstructive than the present limit of two miles prescribed by law. With regard to the power to make bye-laws, he considered this should be given up to a central authority, towns of 100,000 inhabitants only retaining the power to frame their own bye-laws. The witness also suggested that a £10 licence fee should enable the owner of an engine to travel in every part of the country, agricultural engines being exempted. By the term agricultural engine, Mr. Aveling was understood to mean one that was employed by a farmer for his own exclusive use. With regard to the much-discussed extraordinary traffic clause, he thought that this would be satisfactory to owners if amended in two directions, *i.e.*, the action for damages should be brought against the person who initiates the traffic complained of, and not against the owner of the engine, and such cases should be brought before the justices within a reasonable period of time. He would not recommend the granting of licences to drivers, and did not consider the inspection of engines by licensing authorities necessary, if it were made compulsory to insure them in some recognised society which periodically made a thorough inspection of the plant insured by them.

Captain Gaynor, of the Royal Engineers, Chatham, was the last witness called, and gave evidence of the great utility of traction engines to the military authorities, who effected an enormous saving by their use. He said they had eight traction engines in employment, and sometimes hauled as many as six trucks in one train. They had never been prosecuted for damage done to the roads, and did not take out licences for their engines.

It is anticipated that the hearing of evidence will be concluded at the next sitting of the Committee.

LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

PERMANENT WAY.

Sir,—From the letters which have appeared in this week's Engineer, I am afraid that the momentous question of the immediate prevention of accidents on railways, due to matters connected with the permanent way, is about to give place to the consideration of what kind of material shall be used, at some distant future, instead of at once treating for a radical change in more "practices" than the solitary one condemned by Major Marindin.

I am of opinion that plate-laying should be considered more a question of charge and responsibility of the engineer than the inspector of permanent way; and, that with the single change to the lighter steel chair, all else would be right for the present, except—as a poetical bishop once said of the island of Ceylon—only the man would be wrong.

It seems to be quite the thing now-a-days for someone to tell us how much better things are managed somewhere else. Would Mr. Fforde, or any other M. Inst. C.E., be surprised to hear that even had a train of loaded ballast wagons actually been standing in a siding near by, with the necessary labour always at hand, and plenty of opportunities offering to distribute it, that ballast would not have been made use of in time to prevent the Little Bytham accident. Yet it is true that had so much ballast been properly placed in contact with the sleepers, on any—even an "antiquated"—system, that catastrophe might never have happened.

One M. Inst. C.E., at least, does not know all the secrets pertaining to the art and mystery of plate-laying. When a road requires repairs the first thing to be done is to "open out," that is, remove all the ballast from the sleepers, in order that the navvy may better be able to get at the under side of it with his lever and his beater; and be it remembered that the ballast is never cast back until it shall be quite certain that it will not have to be "opened out" again. This can only be determined after trains have gone over it in its incomplete, and possibly dangerous, condition; that is to say, by direct experiment.

In minor repairs—those including a joint or two, more or less—this filling in may immediately follow the lift and one packing, especially where the ballast is ballast and the labour trustworthy. But in more important repairs this would not follow as a matter of course, and in relaying greater lengths still less likely to be done, for the sleepers would certainly have to be lifted again and again. It must not be forgotten again that the presence of an inconvenient quantity of ballast, or that amount which would prevent the beater getting well under the sleeper, is purposely avoided. This was the condition of affairs at Little Bytham, and the absence of an amount of ballast which would have steadied the road was not accidental, it was only the result of another reprehensible practice. This would be all right from a navvy, or ganger, or inspector point of view—in which unfortunately the pay-sheet plays no unimportant *rôle*—if all concerned only knew other than by "rule-of-thumb"—sometimes called "experience"—what ballast might be dispensed with, and how much was required to be present to prevent a passing train of known weight and velocity knocking the road altogether out of shape. The engineer of the line should know this; but then there exist absolutely no data for him or his subordinates to go upon.

Where are the tables which would show us what amount of lateral pressure is exerted, even on a straight road, by the ever-present oscillations of a train of 100 to 500 tons, extending over lengths up to 100 yards, at all speeds up to 100 miles per hour? What positive evidence is there either of the amount of pressure as centrifugal force on the outer rail of curves up to 80 or 100 chains radius, and what amount of opposition to such centrifugal tendency is offered by the *vis inertiæ* of the way itself, plus the friction which would obtain, of various small areas of the under side of the sleeper in contact with the ballast as the load passes over it. What is known of the centripetal, or compensating element, which in this way comes into play, and is absolutely necessary as a per-contra, in the account of safety *versus* danger?

No, Sir, nothing of this kind of information is come-at-able yet, and an altogether new field for investigation is presented; and unless some new method of plate-laying be devised, which will give back to the permanent way its old preponderating margin of safety, such an inquiry will inevitably be forced upon us. Continually increasing weights and higher velocities must be met by corresponding and adequate compensation, or——. I will leave the rest to your imagination.

I was fortunately not in the accident which happened some five years ago near Dijon—France—but I was on the spot by the next through train from Genoa; and I saw at once what was the matter—want of ballast. The official report exonerated the permanent way, because, forsooth, it had just undergone an extensive repair, and the gangs had only just left it. As in the matter of history, accidents repeat themselves also.

Just one word with reference to the machine depositor, spreader, and trimmer. I have very good reasons to object to it, wherever intelligent and decently paid hand labour can be obtained; as the work is then more likely to be well done—that is what is wanted—and, in consequence, the public be better served.

Lilford-road, S.E., May 11th. J. W. Wilkins.

Sir,—Is it not time that your various correspondents who advocate more or less sweeping changes in permanent way should ask themselves why it is that more than 90 per cent. of the rails in this country are carried in chairs on cross sleepers? It is quite certain that chairs are, in a sense, an after thought. The flat-footed, or Vignoles rail, was only given up after years of use. The chair seems to be a survival of the fittest, and before your readers can persuade me that it is not used because forty years' experience has proved it to be better than any of its rivals, they will have to explain on other grounds why it enjoys so extensive a popularity. Why, for example, did the Great Western give up the longitudinal sleeper? Why did the London, Chatham, and Dover give up the Vignoles system? Why did the Great Southern and Western of Ireland give up a 90 lb. ∩ rail on cross sleepers for a much lighter bull-headed chair road? I can understand the advocacy of a steel chair, but I cannot understand the advocacy of the flat-footed rail. Will any of your readers tell us what the relative cost per ton of different patterns of rail is? This is a point that they do not appear to consider at all. Old Ganger.

Preston, May 11th.

THE LIQUEFACTION OF GASES.

Sir,—I am duly grateful to "Zero" for his kind offer to instruct me out of his vast stores of learning. I am loth, however, to trespass on his condescension, for I feel his time would be more profitably spent in studying the proposition that heat cannot of itself pass from a cooler to a hotter body. After reflecting upon this he may see how absurd is the analogy he suggests between the reduction of temperature suffered by the hot gases in a boiler flue, and that undergone by the gas in Hampson's apparatus. In the case of the flue the gas is surrounded by a medium much cooler than itself, and naturally heat passes from it into that cooler medium. Hence the temperature progressively falls from one end of the tube to the other. But in Hampson's apparatus the gas in the tube is enclosed by a medium not cooler than itself. Why, then, should it part with its heat, or become cooler at one point of the tube than at another?

In his first letter "Zero" said we can "fancy a means by which the temperature of the air at one end of a tube will be 500 deg. Fah., and at the other zero." Of course the unrestrained imagination can fancy anything, but science deals with facts, not fancies. What we want to know is why the heat and cold obligingly stand apart in the Hampson machine in the picturesque manner described, until the cold at one end of the tube is so great as to induce a change of state in the gas. But it is just this point that "Zero" has slurred over in all his letters.

The conception of internal work, though a commonplace of the text-books, seems unfamiliar to "Zero," who states that "the energy in a gas is a function of its temperature, and of nothing else." That is not true of the actual gases we meet with in nature, as "Zero" will find by reference to recognised authorities. "Zero" says I have given no scrap of evidence that any energy escapes from within the apparatus to the external world. What I did say was that some energy disappears within the apparatus in doing internal molecular work on the gas itself, and that that disappearance is a fact proved by experiments, which experiments "Zero" shows a curious disinclination to face. The question of its reappearance I did not deal with.

"Zero" in his last letter says it is a simple matter of calculation how much the Joule effect can accomplish, and yet in his first letter he cast doubts upon its very existence, let alone the accurate determination of its amount. If he has found a way of getting exact results from inexact data, it would be worth knowing. But his statement that "Joule's effect" is too small to take account of is not warranted by facts. For air it amounts to slightly over ¼ deg. Cent. per atmosphere difference of pressure on the two sides of the orifice; hence working with about 100 atmospheres the reduction of temperature would be, say, 20 deg. Cent. That is at ordinary temperatures. "Zero" is apparently unaware that the Joule cooling effect increases rapidly as the temperature of the gas employed decreases, or, to put it more properly, as the temperature of the gas approaches the critical point. Therefore, the cooler does the gas in the coils become the greater is the proportional cooling produced. In this way the Joule effect is amply sufficient to account for the action of these "self-intensive refrigerating machines," the efficiency of which, as I said before, is ridiculously small.

If "Zero" does indulge in a mathematical disquisition, I hope he will express all his temperatures either in Fahrenheit or in Centigrade degrees, and not mix up the two scales together, as he has done in his letters. This precaution may make his results less sensational, but not less instructive.

Finally, I should like to pay a tribute to "Zero's" complaisance as an opponent. I ventured in my last letter to differ from his categorical assertion that the expanding gas in Hampson's machine does no external work, with the result that he promptly abandons his contention and cheerfully agrees that it does. Perhaps, now, he will abandon in the same graceful manner his position that the "Joule effect" has nothing to do with this method of liquefying gases. Cryos.

May 6th.

Sir,—In reply to your correspondent, I regret that I am unable to supply the information for which he asks. Indeed, I do not know that Dr. Hampson is in possession of it himself.

A tolerably complete statement has, however, been made concerning the Linde apparatus, and appeared in The Engineer for October 4th, 1895, page 325. I may add that the explanation of the theory given there appears to be Schröter's, and is not sound. The temperature reduction due to the Joule's effect is quite too small to permit the machine to have any commercial success whatever, if it depended on that for its action. Zero.

May 12th.

CIRCULATION IN WATER-TUBE BOILERS.

Sir,—I have to thank you for the note which you were kind enough to append to my letter in your issue of last week. Unfortunately I fail to distinguish which is the point which you appear to have conceded to me, and what it is which you regard as the "main fact." It is important that we should not confuse the issue.

I regard as the main facts that in every case the cause of circulation is the superior pressure of the downcomers due to the greater mean density of their contents, and that the entraining action of the bubbles in the water in the up-tube cannot lift the whole contents, water and steam, as they are lifted bodily, for this would be a violation of the principles of action and reaction, which declares that no material action between parts of a body can move that body as a whole.

Possibly it is on the question of the existence or otherwise of "entraining action" that you imply that we differ. Here I think we are entirely agreed, for although you said in your article of April 3rd "Professor Lambert will have none of it," and now again imply that I do not admit the existence of entraining action, for you say that if I am right a ship has no following wake and a boiler no priming, yet I submit that nothing I have said or written should bear this construction. Certainly entraining action exists. I have gone so far as to explain it by calling it "frictional drag," but I cannot admit that it is the cause of circulation. A ship in motion always has a following wake, and bubbles rising through water have a following wake also, due to their entraining action on the water; but it is not this entraining action which makes the whole mass of bubbles and water ascend bodily in an up-tube of a boiler.

A sailing ship running before the wind has an entraining action, causing a following wake, but this is not the cause of the motion of the ship and water. The real cause is an outside force, viz., the wind pressure, and all motion and entraining action soon cease when this outside force is withdrawn. I venture to submit these observations in response to your kind suggestion that I should write you again on the subject. Carlton J. Lambert.

Royal Naval College, Greenwich,
May 5th.

CANALS.

Sir,—I was much interested by your account of the Thames and Severn Canal in your issue of this week. The people of this country are now feeling the results of the foolish policy of abandoning the canals as soon as railway competition set in.

At one time there was a water communication from Portsmouth to London, *viâ* the Portsmouth and Arun Canal, the river Arun, and the Wey Navigation. The first-named canal was bought up by the London, Brighton, and South Coast Railway, and as it ran parallel to the railway it is scarcely necessary to add that it is now closed. All but a small portion near Chichester is filled in, and little more than a year ago the engine-house for the pump that supplied the canal with water from the Arun was pulled down. This canal joined the Arun about four miles below Arundel. The connection with the Wey Navigation was made by a lock near Pulborough. The river section is still used to a small extent by barges, but the navigation, as such, is so completely abandoned that the landowners have been permitted to obstruct the towing path with stiles, fences, and, in some cases, even hedges.

May 11th. Geo. T. Pardoe.

LOCOMOTIVE FIRE-BOXES.

Sir,—In reading your article on "The Fire-boxes of Locomotive Engines" in last week's Engineer, it recalled to mind a sketch of arrangement of roof stays you illustrated for me in The Engineer of December 5th, 1879, page 414, which, if you will look up, I think will meet your view of the case. The flat-topped fire-box casing with through stays will not do for traction or portable work, where the engine is bolted to the boiler. The stays are in the road of everything, and I cannot see any advantage in the plan for locomotives. Joseph J. Tyrrell.

Stamp End Works, Lincoln, May 11th.

SAFETY IN COLLIERY WINDING.

In connection with recent over-winding accidents at collieries, the following abstract of a paper read by Mr. C. M. Percy, the well-known Lancashire mining engineer, before the members of the Manchester Geological Society, at a special meeting held in the Wigan Mining School, on Friday, will be of interest. Whilst unfortunately, he said, many causes of mine accidents were beyond their control, accidents with colliery winding appliances were capable, with means already at their disposal, of being made well-nigh impossible. What they required was a thoroughly good equipment, and the fundamental essential was an efficient pair of winding engines, which were not liable to get out of order, and amply sufficient to deal with the load. They should be capable of the easiest possible manipulation, and the load must be made uniform throughout the operation of winding, whilst the brake-power should be sufficient to hold the engines to any position. To have a pair of engines was, he thought, sufficient power, and then, even allowing one-third for overcoming frictional and general resistances, they should calculate upon the possibility of only one engine being available. The arrangement of conductors in the shaft was also important for safe winding, especially where two cages worked in the same shaft, and collision had to be guarded against. The general preference was for wire conductors, as they were less likely to become disorganised, and allowed freer winding, besides being altogether more convenient in a pit shaft. Good winding ropes were of course an absolute necessity; the material for the wire had now a strength up to 140 tons per square inch, and the high qualities should always be used. Even with the above precautions, accidents might take place; over-winding might occur, owing to the cage being drawn too high, either by not being stopped in time, or started the wrong way. To prevent this detaching hooks had long been in use, but the prejudice against them had not entirely passed away. It was argued that they made winding enginemen careless, but the contrary was the case. Where they were not applied an over-wind might take place, but unless something broke nothing was said about it; where, however, the hooks were applied, every over-wind made its own record. Accidents were possible, however, even with the most efficient detaching hooks, and Mr. Percy described an appliance in use at many of the Wigan Coal and Iron Company's collieries which had been very effective in the prevention of accidents. Under ordinary conditions this arrangement interfered in no way with the winding engineman and his work, but only acted when the dominions of safety were invaded. An essential part of the mechanism was a governor arrangement worked from the winding engines, which determined the speed at which the cage would be allowed to pass a given point. If the predetermined speed was exceeded, a catch was automatically liberated, and falling weights applied the brake and shut off the steam. The limit of speed was a determinable quantity, and the point of action could be fixed at will. In the discussion which followed several colliery managers referred to the arrangement described by Mr. Percy having prevented what might otherwise have been serious accidents, although there had been cases where even this arrangement had not prevented over-winding, and Mr. Percy remarked that it was necessary they should use the ordinary detaching hooks as well as the arrangement he had referred to.

CATALOGUES.

Diamond Machine Company, Providence, R.I., United States. Grinding and Polishing Machinery.—This is a catalogue of special lathes and lathe appliances, many of which are of novel design and quick action. Emery wheel machinery of various kinds, including planing and shaping machines in which the work is done by emery wheels.

The London Emery Works Company.—In our notice of the catalogue of this company last week, it was mentioned that the otherwise exellent catalogue had not the name on the back. This was so with the early copy we had; but we find that the name is on the back of every copy now sent out. The name and trade mark of the emery and glass paper sent out by the same company is the Atlas brand.

Campbell Gas Engine Company, Limited, Halifax, England.—This illustrates the Campbell oil engines in their various types, the oil engine being shown as applied to marine, portable, and fixed engine purposes. The gas engines illustrated are from 30-brake horse-power downwards, the fixed engines including a very handy little vertical engine of several sizes down to 1½-brake horse-power, useful for many purposes.

Smith and Grace, Thrapston. — Pulleys, Shaftings, Bearings, and all accessories for the transmission of power.—Since Messrs. Smith and Grace began to devote special attention to shafting and mill requirements, they have introduced numerous improvements in pulleys, couplings, collars, and self-oiling loose pulleys and bearings. Their designs are not slavish copies of old patterns, but represent the best practice in this branch of engineering manufacture.

Barry, Henry, and Co., Aberdeen. Price Lists of Conveyors and Elevators.—The economical advantages of the conveyance of materials by mechanical means, such as the steel tray conveyors, the elevators, and the spiral conveyors illustrated in this catalogue, has added experience to that which until only a few years ago guided manufacturers of this class of machinery; and it is now possible, as shown by this catalogue, to obtain machinery of this kind for any purpose.

P. R. Jackson and Co., Limited, Salford Rolling Mills, Manchester. Two vols.—This catalogue is in two sections, the first one relating to the numerous forms of toothed gearing, pulleys, worm wheels, fly-wheels, worms, and other steel and iron castings, and the various forms of manholes, stop valve columns, and other steel boiler blocks, of which the firm have made a speciality. The second section deals more particularly with the pistons and piston rings manufactured by the firm in a great variety of sizes. It also mentions the removable field magnet dynamos made by this firm.

Easton, Anderson, and Goolden, Limited, London and Erith.—The specialities recently, or within the last few years, taken up by Messrs. Easton, Anderson, and Goolden, Limited, are clearly described and well illustrated in this catalogue by excellent engravings. The applications of the dynamo and electric motor are numerous, not only in mining machinery, but also in lifting machinery hitherto operated by steam engines or by fly ropes. The catalogue also describes and illustrates the pulverising machinery now manufactured at Erith, and the pumping machinery of various kinds, water supply machinery, and lifts, for which the firm has long been so well known.

Rose, Downs, and Thompson, Limited, Old Foundry, Hull. Tenth edition.—In this edition of their now well-known catalogue of oil presses, oil kettles, edge runners, and other machinery for treating all kinds of oil-bearing nuts and seeds, Messrs Rose, Downs, and Thompson have included several new machines, chiefly of the smaller sizes, to work by hand-power, similar to those made for export, and working on a combination of the Anglo-American and Box systems. They also show a newly-introduced mill on the Anglo-American system for the treatment of those seeds and nuts which require a second pressing. Other machinery includes plant for fish manure and drying purposes and for the treatment of oils and fats by the fullers earth process.

The Metric System.—The Bill introduced into Congress making the metric system compulsory in this country after January 1st, 1901, has been sent back to the House committee, and the probability of its being adopted in this session is very slim. It will be a good thing if it does not pass in its present form. We believe that the ultimate adoption of the metric system is this country is certain, but to make it compulsory and at such an early date is unwise and would work a hardship to many. Manufacturers who have considerable foreign business would probably reap sufficient benefit from it to off-set the expense to them of the change, but there are many others who have no resulting advantages to look forward to, and these parties deserve more consideration than the Bill mentioned gives them. If it is conceded that the adoption of the system will some time be an accomplished fact, then it is clear that the earlier the change is undertaken the less expensive it will be. The change should not be attempted without plenty of preparation, however, as without it the cost would be excessive and needlessly great. Such legislation as is desired in aid of this movement should be framed on more practical lines than the Bill mentioned. The large manufacturers, if assured that only reasonable legislation was contemplated, would doubtless be able to suggest the lines on which a satisfactory law could be framed. They have a right to be heard in this matter, for upon them will come the great burden of a change. Expensive scales, templates, jigs, drawings, taps, dies, &c., would have to be changed, and this is one of the objections to a sudden and compulsory adoption of the system. But drawings become obsolete, and templates and special tools wear out, and if a reasonable period is allowed in which to effect the change, the manufacturing and engineering industries could doubtless provide a way for reducing to a minimum the confusion and expense incident thereto. —*American Engineer and Car Builder*

Institution of Junior Engineers.—At the meeting of this Institution, held at the Westminster Palace Hotel on Friday, 8th May, the chairman, Mr. H. J. Young, presiding, a paper, "Notes on Belgian Electrical Engineering Practice," was read by Mr. A. Anstruther-Thomson and Mr. G. C. A. Allingham, members. The communications embodied particulars which had been collected by the authors during the Institution's summer meeting of last year. Belgian electrical practice was difficult to define exactly. It was usual to associate English practice with high-speed engines, direct coupled to dynamos or alternators, and continental with slow-speed engines driving multi-polar dynamos; no rigid distinction existed, however. Belgian practice seemed strongly influenced by both the foregoing characteristics, and was therefore extremely interesting as showing a variety of types, and affording exceptional opportunities for comparison. In contrasting English with foreign practice, the advantages of employing a consulting engineer over the foreign plan of giving the contract for the complete plant to some large firm, were indicated. The system of free publication of central station accounts to which in this country we were accustomed, was not adopted in Belgium. Originally high-speed dynamos were driven from slow-speed engines by belts; to secure the advantages of direct-coupling in England the engine speed was increased, whilst on the Continent the dynamo speed was diminished. After briefly touching on the term "load factor," and its influence on central station practice, the preference shown on the Continent for continuous current and large batteries was pointed out. Descriptions were given of some Belgian central stations, the Van Rysselberghe system at Antwerp, and the application of gas engines in sub-stations at Brussels being specially mentioned. The different types of plant in use in Belgium and England were then dealt with, including boilers, engines, steam turbines, dynamos, and batteries. With regard to electricity for power purposes, there were no long distance transmissions in Belgium, and hardly any multiphase plant, but the use of electromotors in workshops was steadily increasing. Several instances were given, notably the important installation at the Herstal Small Arms Factory. In reviewing the question of electric traction, after referring to the Belgian experiments on accumulator cars, the trolley system, in which American designs are naturally largely employed, was considered, and descriptions of two Belgian electric tramways were given. General conclusions appeared to show that in electrical practice Belgium occupied a position intermediate between England and the Continent. The authors expressed their appreciation of the excursion to Belgium, and the hope that the Institution would organise other meetings abroad; to their Belgian hosts their hearty thanks were due for the exceedingly kind reception which had been extended. In the discussion which ensued the following members took part:—Messrs. H. B. Vorley, W. B. Clarke, F. M. Short, A. H. Dykes, Assoc. I.E.E., T. E. Dowse, and K. E. Gaumbe.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

⁂ *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

⁂ *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

CROSSINGS AND CURVES.

(*To the Editor of The Engineer.*)

Sir,—Will you or any reader of this journal oblige a student with the formulæ for calculating mathematically the distances between intersections of crossings, &c., for setting-out permanent way fittings correctly, or give the name of a good treatise on the subject. Student.

May 11th.

[Presumably, as you do not state otherwise, you "take off" from the "straight" and not from a curve. You must have for data the radius of the curve and the gauge of the track. Put the former = R, the latter = g, the angle of crossing = θ, and D = distance from springing of curve to intersection of the crossing. If the difference between R and $g = d$ we obtain

$$D = \sqrt{(R + d)} \times g.$$

For the angle of crossing $\operatorname{cosect} \theta = \frac{R}{L}.$

If instead of R being given θ is known, the value of R will be

$$R = \frac{g}{1 - \cos \theta}.$$

Practical platelayers allow a little margin over and above the calculated length of D, according to the degree of the curve.—Ed. E.]

SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number)	*£0 14s. 6d.*
Yearly (including two double numbers)	*£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. The Engineer *is registered for transmission abroad.*

A complete set of The Engineer *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—	
Half-yearly	*£0 18s. 0d.*
Yearly	*£1 16s. 0d.*
Thick Paper Copies—	
Half-yearly	*£1 0s. 3d.*
Yearly	*£2 0s. 6d.*

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

ADVERTISEMENTS.

⁂ *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of The Engineer.

MEETINGS NEXT WEEK.

Royal Meteorological Society.—Wednesday, 20th inst. at 7.30 p.m. Paper: "The Exposure of Anemometers," by Richard H. Curtis, F.R. Met. Soc.

The Institution of Civil Engineers.—Tuesday, May 19th, at 8 p.m. Papers submitted for discussion: "The Magnetic Testing of Iron and Steel," by Professor J. A. Ewing, M.A., F.R.S., M. Inst. C.E. "Magnetic Data of Iron and Steel," by Mr. Horace F. Parshall, Assoc. M. Inst. C.E.

Royal Institution of Great Britain.—Tuesday, May 19th, at 3 p.m. Lectures: "Ripples in Air and on Water," by Mr. C. Vernon Boys, F.R.S., A.R.S.M., M.R.I. Thursday, May 21st.—"The Art of Working Metals in Japan," by Mr. W. Gowland, F.C.S., F.S.A. Friday, May 22nd, at 9 p.m. Discourse: "Hysteresis," by Professor J. A. Ewing, M.A., F.R.S.

Society of Arts.—Monday, May 18th, at 8 p.m. Cantor Lectures: "Applied Electro Chemistry," by Mr. James Swinburne. Tuesday, May 19th, at 8 p.m. Paper: "Bronze Casting in Europe," by Mr. George Simonds." Wednesday, May 20th, at 8 p.m. Paper: "Orthochromatic Photography," by Captain W. de W. Abney, C.B., F.R.S.

The Institution of Mining and Metallurgy, London.—Wednesday, May 20th, at 8 p.m. Papers to be read: "Estimating and Sampling Ore Reserves, as practised on the Witwatersrand, South Africa," by Mr. Wilfrid Wybergh, Associate. "Notes on the Treatment of Zinc-box Precipitate—'Slimes'—from the Cyanide Process, as practised at the Standard Consolidated Mines, Bodie, California," by Mr. R. G. Brown, Member. "Note on a Safety Hook used in California and other deep mines of Colorado," by Mr. J. H. Collins, Past-president.

THE ENGINEER.

MAY 15, 1896.

ENGINEERS OR ARTIFICERS?

In a recent impression we considered the position of the engineer branch of the Naval Reserve, and we pointed out that our war needs could not be satisfied even if every engineer in the Reserve could be sent to sea in a ship of war. It will be remembered that Mr. Durston, writing to the Institute of Marine Engineers, maintained that The Engineer was in error as regards the supply of engineers available for service; and we suggested that the Admiralty did not contemplate the necessity—or shall we say the possibility?—of fitting out all our available warships at once. It was beyond all question that the statements which we made in our impression for 8th March, 1895, were absolutely correct, based as they were on official statistics. Taking our fleet ship by ship, but excluding harbour ships, and those which would in all probability be unfit for service, it appeared that there were not enough engineers by some hundreds to supply them. The reply of the Admiralty might be that inasmuch as all the ships could not go to sea, it was unnecessary to provide crews for all. The other alternative is that in an emergency the Admiralty would utilise engine-room artificers as engineers. On these points we possessed no positive information. But at the dinner of the Royal Naval Reserve, Mr. Goschen was a guest, and he made a speech which supplies some information bearing on this point. Further back, however, he said in Parliament that at the present moment every ship which could reasonably be sent to sea could be manned without difficulty, explaining, that such a proceeding would involve a draft of some 5000 men from the Naval Reserve. He even went further, and said, "If we were to send every possible ship to sea which is seaworthy, excluding harbour ships, we could man the whole of them, though it is impossible to suppose they could all be ready at once, by taking a draft of 11,000 from the Naval Reserve." It is clear from this that he relies on the Naval Reserve to supply engineers as well as stokers and bluejackets. But it is certain that even with the aid of the Reserve there would not be engineers enough. Mr. Goschen doubtless knows this just as well as we do, and it seems therefore tolerably evident that but one way lies out of the difficulty; he must rely on artificers to discharge the functions of engineers.

Now we do not say that the artificers are not quite competent to do what is wanted; neither do we assert that the artificer is just as good as the engineer for all practical purposes. It is quite unnecessary that we should express here and now any opinion on the matter. We are dealing with the policy of the Admiralty, not with the relative merits or demerits of two classes of men. The Admiralty insist on maintaining a standard of education for naval engineers which is exceptionally high. So much is expected, and the training is so long and laborious, that young men will not enter the Navy as engineers in sufficient numbers, the pay and position representing an inadequate return for the education. In other words, a man competent to pass the Admiralty examination and fulfil the Admiralty conditions can do better than become a naval engineer, the very excellence of his education and training rendering his social position as one the more irksome. But the Admiralty maintain that the high education is essential. How is it, then, that they are prepared to hand over the engine-rooms of our warships to artificers who have not had this training or anything like it, and that, too, in time of war, when all the resources of a scientific training are most likely to be needed? There is, moreover, an aspect of the case which seems to have hitherto escaped everyone who has written or spoken about it. Is it likely that the artificer will be able to exercise sufficient control in the stokeholds should an action be fought, or any unusual efforts be required? Englishmen make, no doubt, the best fighting material in the world, but they require to be led, and the demands which will be made on the nerve of the engineer in time of peril will be excessive, and unless he has absolute control below, and is feared and respected by the firemen, the results of an action may be anything rather than what they ought to be. It is known that in the American war firemen have more than once been kept to their work at the point of the revolver. We believe that an English crew of firemen will do all that men can do, but they will only do it if they are properly led and controlled, and that can only be done by an officer invested with adequate authority. That an artificer cannot possess unless he is given rank as an engineer. If the Admiralty contemplate this, then does their policy appear more than ever anomalous. "It will be seen," says Mr. L. Cathcart, in *Cassier's Magazine*, writing on the rank of engineers in the United States Navy, "that viewed from any standpoint, either directly or by comparison, the duties of the naval engineer officer are essentially combatant and military. To class him as a member of the civil branch is a mistake. Civil officers take no part in military operations, and are not called upon by the nation to risk life in its cause. Justice to him requires that he be given positive military rank in due recognition of his service; and wisdom imperatively requires it in view of the relatively large force of men which he must organise, instruct, and direct in peace, and which in battle, amid grave dangers and sudden emergencies, he must control in the performance of functions vital to the ship."

But this is not all; Mr. Goschen assumes that the staff available at the moment for our ships of war will continue to suffice in war time. There cannot be a greater mistake. It is a matter of common knowledge that even during the naval manœuvres, whenever a ship is driven, drafts have to be made from the deck hands to assist in the fire rooms. Even if this were not so at the beginning of a cruise involving some fighting, what would the position be toward the end? When we hear of important vessels going to sea with one engineer and one assistant-engineer, we wonder what is to happen if one is wounded, and the other fell ill. Is it to be assumed that the engineer of a ship will enjoy an immunity to which any other man in the ship is a stranger? We believe, on the contrary, that in any war the expenditure of engineers will undoubtedly be very heavy, and for this expenditure the Admiralty make, and have made, no provision whatever. It is argued that it would be useless to have more engineers, because there is not a sufficient number of ships available for their training. If it could be shown that the ships in commission are already overmanned in the engine-room department, there might be some reason in this contention; but nothing can be further from the truth. The position as it stands is this: The Admiralty hold that naval engineers must have a very admirable and complete scientific and practical training. They admit that there is not a sufficient number of engineers available to supply all our ships. They hold that all our ships will never be wanted or available at once. Even so they admit that they have not engineers enough, and will draw what they want from the Naval Reserve. But the Naval Reserve cannot supply a sufficient number, and therefore as a final resource they rely on engine-room artificers. Such a policy only needs to be stated to secure its condemnation. It is based on a complete misconception of what would occur in war time, and it is only possible because the engineer is not adequately represented at the Board of Admiralty.

CIRCULATION IN WATER-TUBE BOILERS.

It will be seen from Professor Lambert's letter, which will be found in another page, that the points of difference between his theory of circulation in water-tube boilers and ours are at least few in number. We stated that as for the theory of training action he would have none of it. To this he takes exception. Yet our words are strictly true as far as circulation in a water-tube boiler is concerned. He believes in the entraining action of bubbles; but says that the action does not cause circulation. For the purpose in hand this seems to us to be a distinction without a difference; the main question remains as it was. "In every case," says Professor Lambert, "the cause of circulation is the superior pressure in the downcomers due to the greater mean density of their contents." Here we join issue. We state definitely that the mean density of the water in the downcomers is the same as the mean density of the water in the riser, and that so long as this is the case no circulation can be brought about in the way Professor Lambert suggests. It is true that the contents of the riser weigh, other things being equal, less than the contents of the downcomer. It remains for Professor Lambert to show how, under the circumstances, there can be a greater "pressure"—the word is his own—at the base of the downcomer than there is at the base of the riser. Such an effect could ensue only if the mean density of not the whole contents, but of the *liquid* in the riser was less than that of the liquid in the downcomer. But it is clear that the presence of bubbles of steam in the water can have no effect on the mean density of that water. We have already said that so long as a continuous thread of water extends from top to bottom of the riser, so long will the pressure at the base or junction of the two tubes remain the same for both tubes. Professor Lambert in a previous letter maintained that while what we stated was true of water at rest, it was not true of water in motion. For the soundness of this statement, we really fear that we must ask some proof. In short, for a definite explanation of what the term "mean density" is intended to convey.

Professor Lambert has not, we think, mastered the facts. Let us consider what actually takes place. Let us take first the case of a single glass tube—a test tube—and heat water in it; the depth of water is, say, 6in. A bubble of steam is formed suddenly, or at least rapidly. The immediate effect is to raise the level of the water in the tube by an amount precisely proportionate to the volume of the bubble. The effect is the same as if a cork was forced down under the surface, or more water was poured in at the top. The bubble rises to the surface and escapes, and the water level falls. Why did the bubble rise? Simply because an equal bulk of water fell. The velocity with which the bubble rose could not have been greater than that at which the water fell under the action of gravity. It must, however, be much less because the water, even if at rest, would offer some resistance to the upward movement of the bubble through it. If the bubble was nearly equal in diameter to that of the tube, then the space between its sides and the inner surface of the tube would be so contracted that the rise of the bubble would be very slow. This can be well illustrated by blowing air into the bottom of a small bore tube containing water. Now the rise of a bubble, or bubbles, is one thing, and circulation is quite another. Indeed, a continuous rise of bubbles in a tube may take place without the change of place of any very considerable quantity of water. Going back now to the consideration of the phenomena in a single tube, it is obvious that if the tube were full to the top of "solid" water to begin, the moment a bubble was formed the water would overflow, and when the bubble had risen to the surface and escaped the water would fall back to a lower level. This is an important fact, and must not be overlooked. Seeing that the rise of a bubble represents the fall of an equal volume of water somewhere, let us next suppose that instead of having a contracted single tube with which to work, we have a large open vessel such as a saucepan. In that the bubble will rise through the line of least resistance, and the water will fall through the line of least resistance, and the last will be usually found somewhere near one side of the saucepan. If Professor Lambert will boil very slowly in a glass beaker water containing a few grains of oatmeal or sawdust, he will have before his eyes the picture we wish to draw. If now, instead of having a wide vessel, we use two tubes connected at the bottom, and some distance apart, we can regard their contents as a section, so to speak, cut out of the great body of water in the saucepan, and we have in a word the old familiar U tube. When a bubble of steam is produced near the bottom in the rising leg, the first effect is to raise the level in both legs; but as the load over the bubble is least in the rising leg, the effect will be to make the level in it rise much more than the level in the downcomer for the moment. In a word, water is ejected from the riser in the way we have described, but this is immediately replaced by the descent of the water in the downcomer and a general levelling of the water in the tank or reservoir uniting the two legs of the U tube. If the experiment is properly carried out, coloured water being put into the downcomer and clear water into the riser, it will be seen that the formation and rise of each bubble in the riser will be followed by a transfer of coloured water from the downcomer until the whole is mixed. Heat is best applied by a spirit lamp with a small flame. If the experiment is carried out with two large vertical tubes united by a small horizontal tube, no transfer will take place, the water descending along the sides of the riser, that course offering the least resistance. As the heating goes on and ebullition proceeds, the formation and escape of the bubble becomes continuous, and the water will descend in the downcomer to push the bubbles up; simply because, in the first place, there is no reason why it should not so descend, and in the second place because, it is far easier for it to descend through a tube which is open full bore than it is for it to descend through a tube which is partially blocked by bubbles, round which it would have to squeeze. It is true that the entraining action takes place. The volume rising is represented not only by that of the bubble, but by that of the bubble and the water the bubble drags with it. It will be evident, we think, that circulation in this way is simply a question of the line of least resistance. The bubble rises not of its own volition, but because it is forced up from below. But the mere rising of the bubble in this way is not necessarily accompanied by anything like rapid or efficient circulation. It is often "a toss-up" whether water will descend the downcomer, or descend in the riser round the bubble. It will come down the downcomer only if the resistance to its descent therein is much less than its resistance to descent in the riser. Circulation brought about in this way is a very very feeble thing, as inventors of water-tube boilers know only too well. An admirable example of its feebleness was supplied by the little turning mills or propellers in Mr. Yarrow's experiments, which had to be hung with the utmost delicacy on fine pivots, in order to ensure their rotation.

But, it may be said, circulation is not a very feeble thing in the tremendous rush of water, for example, up the tubes of a Paxman boiler, the top mouths of which had to be fitted with deflectors to prevent the water being dashed against the top of the steam space; see also the rush in Yarrow and Thornycroft boilers. The inconsistency is one of appearance, not of fact. The conditions obtaining are profoundly modified, as will be seen in a moment. When ebullition becomes violent, the water is ejected from the top foot or two of the tube. The steam bubbles fill the whole cross section. There is no longer even a continuous thread of water extending down the riser, and we have a virtual difference of head in the two legs of perhaps two or three feet. Now, a difference in head of even a single foot would give a velocity of 8ft. per second, and a difference of 3ft. would give a velocity of nearly 14ft. per second, or 840ft. per minute; so that even when we have made a considerable allowance for friction, a highly efficient circulation remains. And thus it came to pass that in Mr. Yarrow's experiments, the flyers which turned so dubiously in the downcomers when the rate of boiling was slow, spun round fast enough when the fire was urged, the glass tubes of the risers the while showing that they contained much more steam than water.

We trust that we have now made our meaning quite clear to Professor Lambert. It is our misfortune more than our fault that we have failed to understand him. We believe that the views we hold are identical with those of Professor Watkinson. Everything turns on what Professor Lambert intends to convey by the words mean density. If he could show that the steam was mixed up with the water so as to diminish the hydraulic head, he would be right. The mean density of a mixture of alcohol and water is less than that of water alone, but no mixture of steam and water can have a less mean density in the same sense. To put the matter conversely, are we to assume that a mixture of fine sand and water would exert a greater pressure per square inch than a similar column of water without the sand, because the sand happens to be much heavier than the water?

MAJOR WILSON'S REPORT ON THE CEYLON RAILWAY SYSTEM.

Closely adjacent as the island of Ceylon lies to India, it would not seem as if the management of its railways has been kept as fully up to date as it has been in that continent. From time to time, and especially of late years, complaint has been made both as to restriction of facilities afforded and as to the cost of working. This reached its highest point when it became known that eight very powerful locomotives recently obtained had perforce remained unused because the bridges on several of the local lines were not of a strength to permit of their employment. It was alleged that the necessity for strengthening them had previously been made the subject of representation to the Government by the railway authorities, but that the required funds for doing this had been withheld. Working expenses had also been annually on the increase, and so strong were the remonstrances raised, that at length the Ceylon Government sought from that of India the services of an expert to report upon the whole position of the island system.

In response to the application made, Major Wilson, R.E., deputy manager of the North-Western Railway of India, was selected to visit Ceylon. The report written by that officer as the result of his inspection of the railways of the Colony lies before us. We fear this can only be viewed in the light of a grave indictment of the Government of Ceylon. On a previous occasion we have had to remark upon the shortcomings that had been allowed to prejudice the successful working of one important addition to the local system. This had been of a particularly costly character, it having been designed to meet the traffic requirements of many tea estates of high altitude. It seemed difficult to realise what we have been assured was the fact, that the stations on this extension, when opened for traffic, were without any roads by which they could be approached. Shortsightedness, of which this was but a single instance, would seem, from Major Wilson's report, to have characterised much of the dealing of the Ceylon Government with the railways of which it is the proprietor. Persistent refusal has been made to admit any private competition for the construction of railways in Ceylon. No doubt the revenue of that Colony has benefitted largely by profits made on these in the past; but progress with the development of the systems has been seriously retarded by the policy pursued, while the planters, who are the chief maintainers of the lines, complain that to produce these profits they are severely taxed by inordinately heavy rates of carriage. Major Wilson reports fully upon this allegation. From the statement furnished by him we gather that, approximately, the passenger fares in Ceylon are in proportion 5·12 and 3·84, as compared with 3 and 2·25 on Indian lines with which comparison may fairly be made. As to goods rates, the proportion would seem to be 1·76 and 1·20 in Ceylon, against ·66 to ·16 in India. There is, therefore, evidence that the outcry raised by the Ceylon planters has not been without warrant; and when we consult the comparative tables given as an appendix to the report, we find this conclusion strengthened by the statement that the average sum received in Ceylon for the carriage for one mile of one ton of goods has been 29·32 pies, against 5·24 pies on the East Indian Railway, and 5·27 pies on the Sind-Pishin section of the North-Western Railway of India. The last was selected by Major Wilson as having features much in common with those lines in Ceylon that are within its mountain zone.

We cannot attempt to follow the report through all its elaborate dealing with the many items of comparison made. It may, however, be quoted, as summarising that comparison, that the working expenses of the Ceylon lines amount to from 53·19 to 66·04 per cent. of gross earnings, as against 27·44 on the East Indian Railway. Under this heading the Sind-Pishin section above referred to does not come into comparison, it being a purely military line with very restricted traffic, and worked at a heavy loss to the Government. Major Wilson admits that the rates charged on the island railways, though heavy in comparison with those of Indian lines, are not excessive when the working expenses are taken into account. He contends, however, that these last should be capable of great reduction, and that much of the procedure involving them is out of date and uneconomical. The expert probably travelled beyond his commission when commenting, as he has done in his report, upon the routes adopted for the several Ceylon railways. The opinion he offers as to these is, in several instances, of a very adverse character; but it may well be doubted if the brief inspection of them he was able to make could render him competent to judge on points that had taxed to the utmost the ingenuity and professional knowledge of such engineers as Colonel Moorsom, Mr. W. T. Doyne, and Sir G. L. Molesworth. In other respects the report would seem to hold the balance between India and Ceylon with the utmost fairness.

It is natural, we suppose, that Colonel Wilson should incline towards a preference for Indian methods of administration and working, but at least he cites sufficient of chapter and verse to justify such a preference. After reading his report, the conclusion is forced upon us that the condition of things as regards the Ceylon railways is largely due to that island being considered a sort of "pocket borough" by the Colonial-office. The admission of outside light, of the experience that is daily extending, is denied to its railway administration. Highly successful as its lines have hitherto been in a financial sense, things relating to them seem to have got into a deeply worn rut or groove, needing external assistance for extrication. The sooner this is recognised by the Colonial-office the better must it be both for the working of such lines as have already been constructed, and for the much-needed further development of railway facilities throughout the island. This further development we learn to be urgently demanded; but to judge from the slow progress in the past, it is not likely of rapid attainment under the ultra-conservative policy pursued in Downing-street. Massive railways of 5ft. 6in. gauge, although perhaps well suited to the heavy traffic to and from the estates in the mountain zone, are not of the character that can ensure this rapidity. Mr. Chamberlain regards the Crown Colonies as being within the category of his "improvable estate." To develope this in the case of Ceylon evidently requires a complete change of the railway policy that has brought about the state of things therein existing as revealed by Major Wilson.

◆

THE ATMOSPHERE OF GREAT TOWNS.

A determined battle has been fought of late years for life under more cleanly conditions in the populous centres of the Midlands and the North. Manchester has been signally successful in smoke suppression, largely through vigorous enforcement of the law. There is no need for fresh legislation on the subject; the need is for compelling observance of that which exists. Now, Sheffield has taken up the work in earnest. A Smoke Abatement Association was formed some considerable time ago. Its object was chiefly educative and persuasive. It now seems as if a new departure was about to be undertaken. Nowhere had the doctrine of black smoke and good business being inseparable taken deeper root than in Sheffield. People had got it firmly into their heads that if they were to have brisk trade they must submit to the dusky billows of smoke which used to strike strangers passing through the city—the two stations being right in the region of the tall chimneys—with mingled awe and amazement that people could exist under such conditions. The Smoke Abatement Association set itself to prove that it was possible to do a great deal of work without being smothered with filth in the doing of it. One means employed was to have a series of competitions amongst engine tenters and firemen. The results of these competitions having been carefully ascertained, his worship the mayor—the Duke of Norfolk, G.M.—presented the prizes at a public meeting held in the Cutlers' Hall on Wednesday, when addresses on the subject were delivered by Professor Ripper, Sheffield Technical School; Mr. A. E. Fletcher, late her Majesty's Chief Inspector of Alkali Works; and Mr. Fred. Scott, the secretary of the Manchester Committee for Testing Smoke-preventing Appliances. The attendance included many engine tenters and firemen, as well as members of the general public. A feature of the gathering was the exhibition of models of smoke-preventing appliances, which were explained by persons familiar with their working. The committee of the association, however, lay great stress on the fact, which they have successfully demonstrated, that smoke-prevention does not require costly apparatus, but can be secured by the existing means at the manufacturers' command, given sufficient boiler power, careful stoking, and due regard to the construction of the furnaces. Having made it clear that smoke is not essential, the Abatement Association will proceed, in the event of the offence being persisted in, to compulsory means of enforcing the law, and where neglect is continued, compel that cleanliness to which it is held the general public are entitled, to say nothing of the workers who live in the neighbourhood. "You cannot afford to make smoke," has been urged upon employers for a long time. Some of them have paid heed to the warning and benefitted themselves and others thereby; the majority, however, are still making as much dirt as ever, and it is high time they were vigorously dealt with, that the reproach so long and justly hurled at Sheffield may be wiped away.

THE HYATT-HENOCHSBERG GOLD EXTRACTION PROCESS.

This process is a pneumatic amalgamation process, in which the finely pulverised dry ore, propelled by a current of air, through a restricted channel, encounters in its way sundry pools of mercury, and was to be seen on Wednesday, the 13th inst., at work at the office of Messrs. John H. Hackworth and Co., Queen Victoria-street. The apparatus consisted of 18ft. of 3in. piping, coiled into a four-coil spiral and mounted horizontally; one end of the spiral projected into a dust chamber, the other end served for the attachment to the air machine, in this instance a hand-power Root's blower. At the top of the first limb of the first coil the feed-hopper was fixed and communicated with the interior by a pipe continued some way down, and provided at the throat with a balanced swing valve that prevented escape of air, but yielded to any slight pressure from above. The lower ends of the spiral were detachable and had been charged with mercury before the arrival of the visitors, the quantity used being insufficient to entirely obstruct the passage. Material representing ore, and consisting of silver sand, to which coarse and moderately coarse gold had been added, in the presence of the visitors, was charged in the hopper, the blower was set to work slowly, and soon a cloud of dust would be seen issuing into the dust chamber. After some little time and the expenditure of much work on the blower, the sand had disappeared from the hopper, the blower was stopped, and the lower parts of the coils were detached severally, and examined separately; they contained clean, bright mercury and a not inconsiderable proportion of sand. The mercury was subsequently found to contain gold, as might be supposed, the bulk of it being in the first bend. The demonstration was conducted by Mr. Hyatt, the inventor, with the assistance of Mr. Hackworth, from whom we ascertained that the apparatus used was capable of dealing with five tons of ore in a day of ten hours, and would save from 80 per cent. to all of the gold; and that apparatus of any size and capacity could be constructed; such being the case, there would be a large and useful field open to this appliance wherever dry free milling ores are encountered. The inspection demonstrated clearly that the apparatus was of admirable simplicity, that it could be very easily worked, that a moderate current of air, stated to be about 1¼lb. per square inch, sufficed to carry away most of the sand, and that much if not all the gold remained; but owing, as is frequently the case on such occasions, to an absence of the necessary data, it is impossible to judge whether the work done had been effected at the rate of 6 cwt. or five tons in ten hours, whether or not all the gold had been saved, whether it was accompanied or not by a loss of mercury, and whether or not it could deal with different class material successfully. But anyway the apparatus is so simple, and can certainly not be very expensive, so that it should be well worth the while of mining men, requiring an appliance for treating dry free-milling gold ores, to bear this process in mind.

THE MARINE ENGINEERING LOCKOUT.

IN reference to the dispute in the Northern engineering trade, it would be in the highest degree regrettable if, at the present time, when shipbuilding is active and large orders are in hand, the current and anticipated prosperity should receive a check or be thrown away through an insane conflict between capital and labour. All must earnestly hope that an amicable settlement will be speedily effected, and we are glad to see that the gradual locking out of from 10,000 to 12,000 men on the Tyne, Wear, and Tees, will in most cases be postponed for a fortnight in order to give the men full time to consider their action and the position it would place them in, so that there is hope that the breach may yet be healed before the notices expire. This action is a significant comment on the speech of Mr. James Hall, at the Newcastle and Gateshead Chamber of Commerce, on the occasion of the recent annual meeting of that body, when—probably foreseeing the turn affairs were taking—he strongly urged how suicidal was the policy of strikes to both capital and labour. We notice also that the same line was taken in a paper read at the British Iron Trade Conference by Mr. W. Jacks, on "Continental Competition," in which he said:—"Since I have been connected with business I have never known a serious strike which had not disastrous results in the country, from the carpenters' strike, which drove shipbuilding from the Thames, down to the ill-starred Scotch coal strike of 1894." Strikes, he pointed out, alarmed capital and prevented its employment in home industries. Never in the history of the world was there such an amount of accumulated wealth seeking investment, but the holders prefer lending it at 2 or 3 per cent. on stable security, rather than invest it in industrial undertakings, on account of the insecurity of the latter. We hope that the men, looking back upon the disastrous losses inflicted upon both employed and employers by the conflict upon the Clyde and at Belfast, which must still be fresh in their remembrance, will meet the conciliatory spirit shown by the employers in an amicable manner, and avoid a dispute which they seem too ready to precipitate instead of making any possible effort to avert it.

SAFETY IN CAISSON WORK.

THE construction of bridges, where the foundations for pillars have to be laid under water, has always been accompanied with danger to the lives of workmen working in caissons. Investigations by Rameaux, and more especially by Paul Bert, have fully demonstrated why air compressed beyond a certain degree is always dangerous to animal organism. According to a recent report of the United States Consul-General at Vienna, Dr. Neudorfer, an Austrian authority, who has made a scientific study of the subject, suggests various methods for obviating this danger. There are two things that the workers in caissons have to guard against:—(1) The concentrated oxygen, which, at a pressure of five atmospheres, affects the nervous system injuriously, causing cramp, tetanus, oxidation, and the formation of carbonic acid gas. It has been proved, he says, by experiments on men and animals that when there is an increase of 20 per cent. in the amount of oxygen, the process of oxidation in the body is less rapid, less carbonic acid gas is formed, and the heat of the body is diminished. The first danger is the least serious, as the pneumatic pump causes a gradual compression of oxygen, to which the system gradually adapts itself, and in any case there are premonitory symptoms which make it possible to remove the workmen before the case becomes dangerous. Little inconvenience is caused until the pressure exceeds four atmospheres. (2) The concentration of nitrogen, which affects the blood instead of the nervous system. With the increase of pressure, the nitrogen becomes more and more concentrated, and the absorption of this gas by the blood increases proportionately, when a decrease in the atmospheric pressure occurs proportional to a smaller density of nitrogen, the gas escapes in fine bubbles, which pass through the veins and prevent the blood, by its expansion, from circulating in the capillary veins. This checks the flow of arterial blood and affects the spinal column and the brain. In experimenting with animals, death is caused instantaneously when a high-pressure is suddenly reduced. The best method for obviating this danger is to reduce the pressure slowly, so that the blood can get rid of the free nitrogen gradually. At the entrance to the caisson there should be a separate compartment filled with compressed air. When the workman desires to leave his work he should shut himself in this compartment, and gradually reduce the pressure by letting the compressed air escape. An hour and a-quarter should be spent in reducing the pressure of 3½ atmospheres, so that the rush may be as small as possible. The decrease of pressure is regulated according to the regulator of Denayrouze. In cases where, in spite of all precautions, a workman is affected, inhalations of pure oxygen are found to be the most simple and effective remedy. Dr. Neudorfer does not seem to be aware that caissons with air locks are constructed with this separate chamber, but an hour and a-quarter seems a long time for making the change from one pressure to the other. The whole statement is a good specimen of Austrian physiology, and will probably be contradicted in a month, as the manner of German physiologists is.

LITERATURE.

Torpedoes and Torpedo Vessels. By Lieut. G. E. ARMSTRONG, late R.N. London: George Bell and Sons. 1896. Price 5s.

THIS work constitutes one of a series of handbooks on matters connected with the Navy, which are being issued by Messrs. Bell and Sons, under the editorship of Commander Robinson, author of "The British Fleet." This volume seeks, in the words of the author, "to convey to the mind of the general reader an elementary knowledge of the most modern development of naval warfare, namely, the science of torpedoes." He remarks with truth that hitherto "all the books which have been written on the subject are of so detailed and technical a nature that the ordinary man in the street has been entirely precluded from learning its intricacies." Consequently, submarine warfare has always been invested with a certain amount of mystery which it is difficult to dispel. But in the opinion of the author there is no reason why the average Englishman should not be as versed in this subject as in any other branch of naval warfare. He considers such knowledge desirable, believing the next great naval war will bestow upon the torpedo and its users a halo of romance, which will eclipse entirely that surrounding the gun and the ram. Another point in favour of this contention is that the torpedo, as applied in the swift craft of to-day, is the weapon of the young officer desirous of mounting the highest pinnacle of fame by executing deeds which have their counterpart in the cutting-out expeditions of old. While recognising fully the desirability of the general public having a knowledge of torpedo warfare, and the methods by which it is carried out, we do not think it is possible to combine this with details of construction in such a small compass as this volume affords. An adequate description of the elaborate mechanism by which the Whitehead torpedo is manipulated, mechanism which has been developed and perfected during an experience of twenty years, would require for that portion of the subject alone a volume of twice the size. The ordinary individual does not require this, while such information is furnished to the expert by official manuals. In a handbook it would suffice to give a general description of the Whitehead, the system of propulsion, plan for keeping an uniform depth, and method of ignition on striking an object. In a chapter of twenty-three pages no more is possible, but the attempt to give minor details leads to principal features being dismissed in a few words. Perhaps the most notable advance in the Whitehead torpedo is that which first enabled it to pass from a speed of 10 knots an hour to 20 knots, by the adaptation of the three-cylinder engine of Mr. Brotherhood. Previous to this the torpedo could not be considered a practical weapon. Successive improvements in the propelling machinery, and other portions, have resulted in a speed for 600 yards of 30 knots. There can be no doubt that the present position of the Whitehead torpedo is as much due to the exertions of Mr. Brotherhood in perfecting the engines, as to the talented man after whom the torpedo is called. In this volume only twelve lines are devoted to the engines, and after an imperfect description we are told, "the great advantage of these three-cylinder engines is that there is no possibility of their being hung up through getting on a dead point!" In the chapter on the different methods of discharging torpedoes little is said as to the advantages and disadvantages of effecting this from above or below water. For a long time the simplicity of the arrangement by which a torpedo was ejected into the water from a port, and then sped on its way, led to all our early ironclads being so fitted. The only modification was when the increased speed of the submarine projectile, and its tendency to dive when dropped from a height, led to special orifices just above the water-line being made for above-water torpedo discharge. There were difficulties in shooting torpedoes from the broadside under water in ships of high speed. These have been overcome. But what changed the whole situation and position of Whitehead torpedoes both in ships and boats was the great development of quick-fire guns. The liability of the torpedo to be destroyed, its air chamber burst, and its large charge of gun-cotton exploded by the projectiles of quick-fire guns, when mounted behind unarmoured sides, led to increased attention being given to discharging the torpedo from below the water-line where it is protected. Most of the difficulties alluded to have been overcome, and now all large ships, even cruisers, are being fitted to use the Whitehead torpedo in this manner. This important part of the subject is not dealt with in this volume, and the ordinary reader will fail to grasp from it the leading principles upon which our ships are now equipped with a weapon which the author considers the "outcome of the highest mechanical ingenuity and perfection of construction."

In dealing with torpedo boats and catchers Lieut. Armstrong is more satisfactory, and this part will be read with most interest by those who desire to acquire information on this interesting subject. The development of the torpedo boat, from the craft 80ft. long to the present dimensions of 140ft., is clearly described. Our early unwillingness to add to the torpedo flotilla is deprecated, but not altogether attributed to the right cause. It was considered then that the torpedo boat was the arm of a nation which stood on the defensive at sea, and hence should not be largely represented in our fleet. What we should have done then is what we are doing now, procure larger and faster boats to act as catchers, which is the proper antidote to hostile craft of this description. Instead of this, we eventually took up the construction of the sea-keeping torpedo vessel, first in the Scout and then in the Rattlesnake class. Lieutenant Armstrong speaks in very disparaging terms of the latter type, and condemns the Admiralty for persisting in their construction. There is no doubt that the speed of some of these vessels has not come up to what was anticipated; but they are good sea boats, and habitable vessels. Though a much higher speed has been attained with the later catchers of the Hornet class, they will not stand much rough usage, and the breakdowns among them have been numerous. For narrow waters they would be of great service in hunting down hostile torpedo boats; but for ocean work, or even the Mediterranean, it is doubtful whether they fulfil the necessary conditions.

A lack in this volume is of any detailed account of what the torpedo has done, in those wars where it has been used. A short account is given, it is true, in the concluding chapter, of some torpedo attacks in the China-Japan War, and the vessels sunk at Wei-hei-wei; but no deductions are made, or any ideals imparted as to the future of the torpedo in naval warfare. Some good illustrations are given, and it is well brought out by the publishers. Though lacking in some respects, the volume will no doubt interest others besides "the man in the street."

SHORT NOTICES.

The Flashing Point of Petroleum. By Dr. Lobry de Bruyn, Amsterdam. Translated from the *Chemiker Zeitung.* 1896, No. 26.—The author of this pamphlet is the chemist to the Dutch Navy, and it originated in the discussion which followed on the wish expressed by the Congress of Fire Brigades that the flashing point of petroleum should be raised to 104 Fah. The pamphlet is one which is of very considerable interest just now, in view of the probable modification of our rules on this subject. The author comments severely on the present low test adopted for oil used in petroleum lamps, and supports the increase of the flashing point on the ground of the present danger and loss of life and property.

Petroleum Legislation: Its Necessity, its Failure, and the Remedy. Reprinted from the *Oil and Colourman's Journal*, April 1st, 1896.—This is a useful discussion of the main points to be considered with respect to the use of the petroleums now so generally employed, and so often with fatal results. It gives a statement of the standards of petroleum used all over the world, which shows that the test is a higher one in nearly every country than our own, and it condemns the Abel flash test as giving a lower standard of safety than was previously used or was intended.

Crossley's Otto Gas and Oil Engines as applied to Pumping at Public Works. Crossley Bros., Ltd., Engineers, Openshaw, Manchester. Manchester: George Falkner and Sons, The Deansgate Press.—This is not a catalogue, but a collection of extracts from numerous journals describing installations, supplemented by detailed information supplied by the firm, and profusely and admirably illustrated. The book cannot fail to be of use to any and every one interested in pumping either on a small or a large scale, whether for town or house supply, or for the disposal of sewage.

BOOKS RECEIVED.

The Naval Annual, 1896. Edited by T. A. Brassey. Portsmouth: J. Griffin and Co. London: Simpkin, Marshall, and Co. Limited.

The Old Light and the New. Dealing with the Chemistry of Colour and the New Photography. Illustrated. By Wm. Ackroyd, F.I.C. London: Chapman and Hall, Limited. Price 1s. 6d. net.

Thames Bridges, from the Tower to the Source. By James Dredge. Reproduced from *Engineering.* To be completed in seven parts. Part I., price 5s. London: Office of *Engineering.*

The Water Supply of the City of New York, 1658 to 1895. By Edward Wegmann, C.E., M. Am. Soc. C.E. First edition. First thousand. New York: John Wiley and Sons. London: Chapman and Hall, Limited. 1896. Price £2 2s. net.

Catalogue of the Hopkins Railway Library. By Frederick J. Teggart, B.A., Ass. Librarian. Palo Alto, California. Library of the Leland Stanford Junior University. 1895. Price 1·50 dols. bound, 1·25 dols. unbound.

Modern Stone-cutting and Masonry. With special reference to the making of working drawings. By John S. Siebert, C.E., and Frederic Child Biggin, B.S. First Edition. First thousand. New York: John Wiley and Sons. London: Chapman and Hall, Limited. 1896. Price 6s. 6d. net.

Shop Kinks and Machine Shop Chat. A series of over 500 practical paragraphs in familiar language, showing special ways of doing work better, more cheaply, and more rapidly than usual. By Robert Grimshaw, M.E., &c. With 222 illustrations. London: Sampson, Low, Marston, and Co. 1896.

The United States Public Works. Containing a Summary of the Methods of Construction and Character of Materials and Plant used in Public Works under the Charge of the War and Treasury Departments, and of the Commissioners of the District of Columbia, including Works of River and Harbour Improvement, Buildings at Posts of the United States Army, Lighthouses, Public Buildings, Life Saving Stations, and Works of Municipal Engineering of Washington, D.C., &c. Published as a Book of Reference for all persons interested in the Public Works, and for Engineers and Contractors in general. By Captain W. M. Black. Illustrated by over forty photogravures and working drawings. New York: John Wiley and Sons. London: Chapman and Hall, Limited. 1895. Price 21s. net.

HORSELESS CARRIAGE NOTES.

IT is satisfactory to find that the Royal Agricultural Society is taking up the horseless carriage as a thing to be encouraged, and although the society does not lead in this matter, it is well that it should give a prize for vehicles specially suited to agricultural purposes and districts.

The draft regulations for the proposed competition in connection with the Manchester meeting of self-moving vehicles for light and heavy loads had been amended and settled, and they are now submitted for the formal approval of the Council as follows:—

Regulations for Competition of Self-moving Vehicles for Light and Heavy Loads at the Manchester Meeting of 1897.

(1) The competing vehicles will be divided into two classes, the one for light loads and the other for heavy loads.

(2) The light-load class to be for such vehicles as would take the place of a light spring cart for the conveyance of loads up to two tons. The heavier vehicles to be capable of taking five tons, exclusive of the weight of the vehicles.

(3) Prizes of £100 and £50 will be offered for the best machines in each class. In the case of equal merit in either case the prize money may be equally divided.

(4) In both classes the self-moving vehicles are to be propelled exclusively by mechanical means.

(5) In the case of oil engines heavy oil alone shall be used; Sp. G., ·8; flashing point not less than 73 deg. Fah.

(6) The design of engine and form of vehicle will be left entirely to the manufacturer.

(7) Trials will be made of the engines carrying a declared weight for an ordinary load over a distance not less than 50 miles out and 50 miles return, during which run the consumption of fuel, water, &c., will be carefully noted.

(8) The maximum speed to be at the rate of ten miles per hour.

(9) Such further trials as the judges may consider necessary to test the efficiency of the vehicles ascending or descending hills will be made.

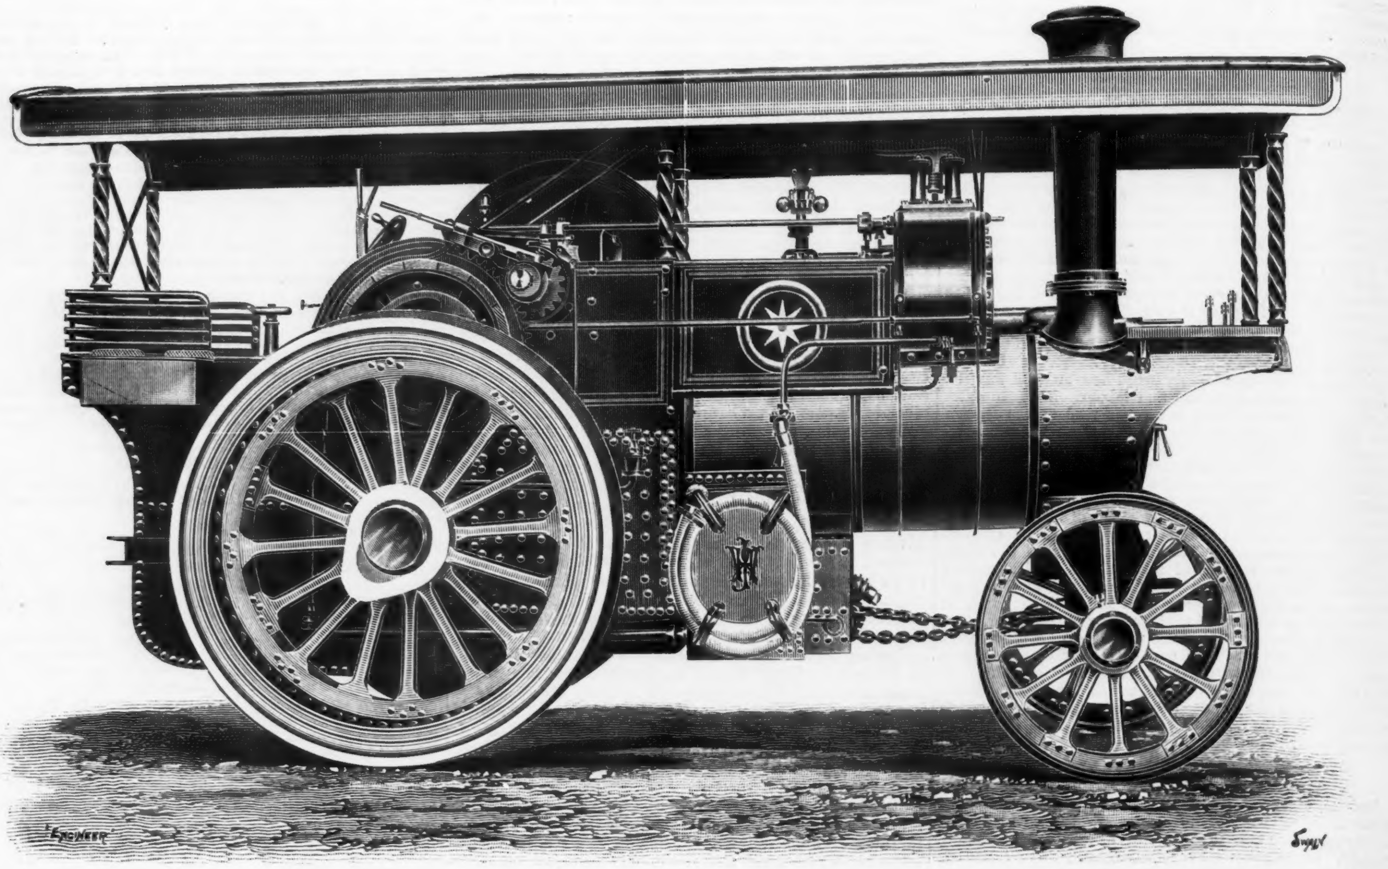
(10) The points to which the special attention of the judges will be called for:—Due regard to the convenience of the public. Ease of handling, with special reference to stopping, starting, and steering. Economy in working. Price. Simplicity. Strength of design. Weight of vehicle.

These are the draft regulations, before the final conditions are published perhaps some modifications may be made.

THE wide belief in the necessity for encouraging the production of satisfactory mechanically-propelled vehicles is further shown by the action of the Shropshire and West Midland Agricultural Society, which offers prizes, as will be seen by our advertisement columns, of £10 and £5 in open competition for "auto-cars or horseless carriages best adapted for rural districts."

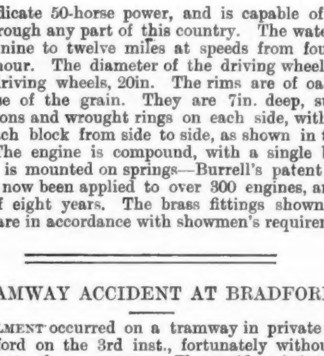
COMPOUND TRACTION ENGINES

MESSRS. CHARLES BURRELL AND SONS, THETFORD, ENGINEERS



TRACTION ENGINE WITH WOOD RIMMED WHEELS.

We illustrate above a traction engine, very similar to, but larger, than one shown by Messrs. Burrell at the Crystal Palace. The principal feature of novelty in the engine is Mr. F. Burrell's patent wood block wheels. The engine at the Palace is a light 6-horse power compound road locomotive weighing 7 tons, and capable of hauling 17 tons gross load up 1 in 15, and working on from 3 to 4 cwt. of coal for a day's run. The engine is double-geared; that is, each wheel is driven independently with compensating gear on the countershaft. The engine is not on springs. The engine we illustrate is one of thirty-five supplied to leading showmen in this country, and is provided with a dynamo support in front.

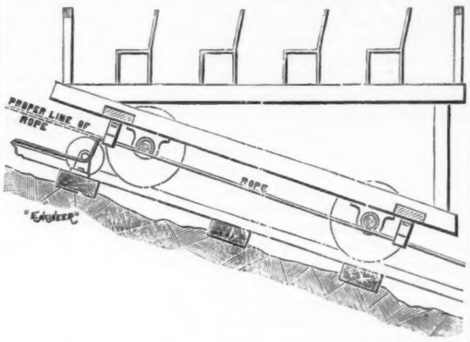


It will indicate 50-horse power, and is capable of hauling 50 tons through any part of this country. The water supply lasts from nine to twelve miles at speeds from four to six miles per hour. The diameter of the driving wheels is 7ft.; width of driving wheels, 20in. The rims are of oak blocks set endwise of the grain. They are 7in. deep, supported by angle irons and wrought rings on each side, with a rivet through each block from side to side, as shown in the cross section. The engine is compound, with a single balanced crank. It is mounted on springs—Burrell's patent system, which has now been applied to over 300 engines, and stood the test of eight years. The brass fittings shown in the engraving are in accordance with showmen's requirements.

TRAMWAY ACCIDENT AT BRADFORD.

A DERAILMENT occurred on a tramway in private grounds near Bradford on the 3rd inst., fortunately without doing bodily harm to the passengers. The accident is interesting, as giving a hint as to a source of danger to be avoided.

The tramway in question has recently been constructed in Shipley Glen, a favourite place of resort for Bradford people, and conveys passengers up an incline. The line is double, and is worked by an endless rope, the power being supplied by a gas engine. As one car ascends the other descends, and the rope has its direction changed at each journey. The cars are slight structures, made with an approximately level platform, and are only wide enough to take two passengers abreast. There is no fence or arm at the end of the seats. The cars are without springs or brake, and no attendant travels on them. In the event of the rope failing, the cars would have a run to the bottom, hindered only by the drag of the trailing rope. The gauge of the line is about 21in., and the rails consist of battens about 3in. by 2in., on the upper surface of which strips of iron ¼in. by 1½in. are fixed by wood screws. The battens are nailed to sleepers, and the line is so laid that a ride on it at ten miles an hour is decidedly trying to the nerves.



The winding machinery is operated by the man at the top of the incline, and the line being curved he cannot see the lower end. The cars were not stopped at the proper place in one journey, causing a collision with the stops. The lower car had its ends broken, and the stops were also injured. The passengers were severely shaken, and there were some who complained of bruises on the shins caused by the seats in front of them. The collision appeared to have caused a surging in the rope—of steel wire about ½in. diameter—as it was off the guide pulleys for about one-third of the way on the line of the ascending car. This was at the upper end, and well in view of the man who was winding, but instead of lifting the rope on by hand he trusted the guide on the car to lift it. The ascending car did pick up the rope until it came to a pulley, where the spindle was projecting. The rope got under this spindle, and an accident was a certainty. A gentleman in the front of the car held up his hands as a signal to stop, but no notice was taken, and the car went over the bracket. Fortunately the rope did not break, but the bracket was torn up and the car derailed. It ran thirty or forty yards over sleepers and ballast, one pair of wheels being over the ends of the sleepers. One gentleman jumped off, but the other passengers kept their seats. There was naturally great alarm amongst them, but no physical injury was done.

A sketch appended shows the cause of the accident. It is in nowise to scale, nor is it intended to illustrate the construction of the car.

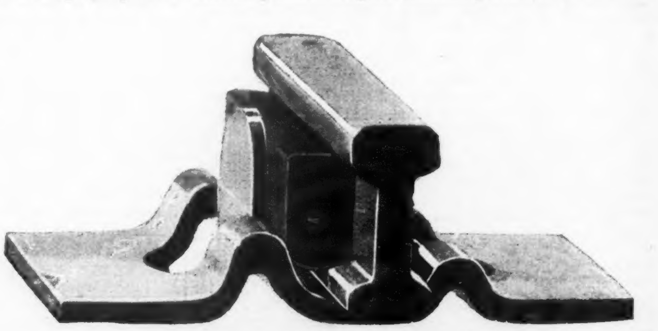
THE Admiralty have invited tenders for the construction of a defence boom in Southampton Water to extend from Calshot Castle to the opposite shore.

MASONRY DAMS—REMSCHEID AND CHEMNITZ

IN THE ENGINEER, vol. lix., 1885, we published an illustrated account of the Remscheid waterworks, and of the arrangements adopted for securing a supply chiefly by pumping from natural underground reservoirs partly formed by building intercepting walls. On page 494 we now publish a view of the handsome masonry dam which has been erected for the Remscheid water supply, and on the same page is a view also from a photograph of the dam built in connection with the Chemnitz water supply. In a future number we shall give some particulars of both.

HARRISON'S PATENT STEEL RAILWAY CHAIR.

WE give below a sketch of this chair. These chairs have now been tried on the Glasgow and South-Western Railway for over eighteen months, and to all appearance are as good as new. Orders are, we are told, now in course of execution for the Great Northern, North-Eastern, Caledonian, and Hull and Barnsley Railway Companies. The weight of the chair is only 18 lb., against an average weight of 50 lb. of cast iron chairs; and as regards cost—if manufactured in quantities—a reduction of 25 to 35 per cent. per chair would be, we understand, obtained, and a much longer life assured. The chairs are manufactured from 8in. flat steel bar or sheared plates, corrugated and stamped out, as in the sketch.



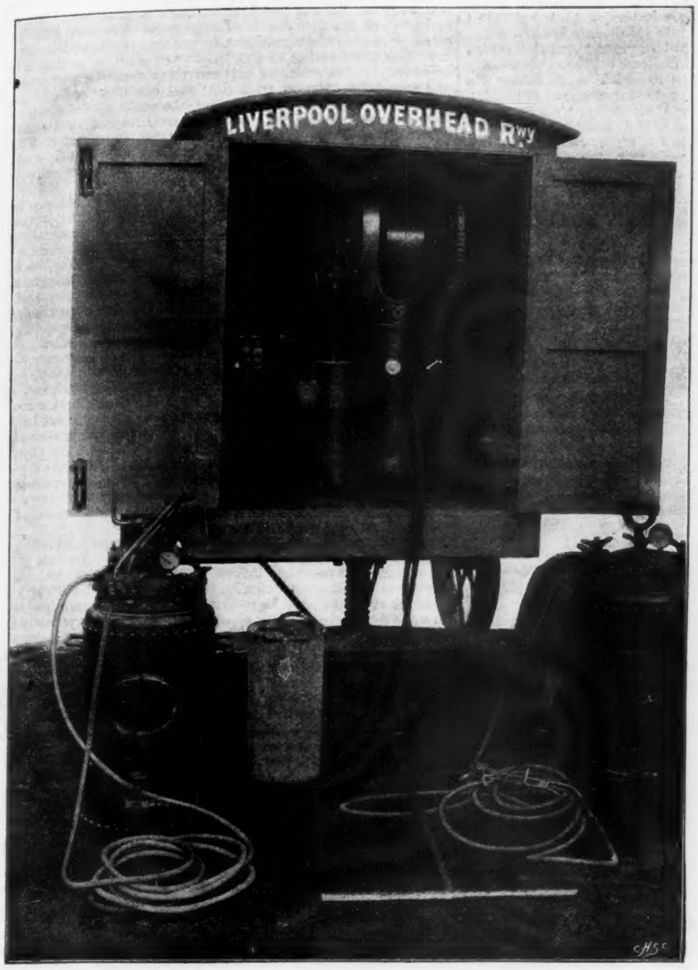
STEEL RAILWAY CHAIR

The patentee recommends a steel of 35 tons breaking strain per square inch, and 20 per cent. elongation in 8in. With such a steel the maximum amount of strength, combined with ductility, is obtained, and they should be practically unbreakable. The chairs manufactured up to the present have been ½in. thick, which, as far as the experience gained, has proved to be quite equal to any stress or strain they may meet. Mr. R. M. Harrison, C.E., of 228, West Regent-street, Glasgow, is the patentee.

A LOOSE boiler on the steamer St. Pierre caused the loss of the vessel early in March. The steamer had been purchased by the Canadian Pacific Steam Navigation Company, and was on her way from Halifax, N.S., to Victoria, B.C. The rolling of the vessel during the heavy weather prevented the boiler from being secured, and the feed pipes were broken. Sail was set, but the vessel began to leak and the crew was taken off by the Hamburg-American Line steamer Normannia bound for the Mediterranean.

ELECTRIC-DRIVEN PORTABLE PAINTING MACHINE.

In our Lancashire Notes recently brief reference was made to a specially-designed portable painting machine which was being constructed by Messrs. A. C. Wells and Co., of London and Manchester, for the Liverpool Overhead Railway Company. The accompanying illustration is taken from a photograph of the completed machine, as supplied to the company, and will, no doubt, be interesting to our readers. It may be added that Mr. Cottrell, the engineer and general manager of the Overhead Railway Company, had for some time past been casting about for a cheaper method of painting the large surface of iron girder work upon which the railway is built, the ordinary hand process involving a very considerable item of expenditure. After making several experiments with one of Messrs. Wallwork and Wells' "Lightning" painters, of which an illustration and description was some time back given in The Engineer, Mr. Cottrell had the above special carriage designed by the inventors and fitted with an electric motor, driven by power from the existing current. The motor is connected with one of Messrs. Wallwork and Wells' double air compressors, which supplies the necessary power to two of their No. 2 size painting machines. The car is arranged to carry the whole plant, and can be wheeled upon the tram lines underneath the railway. Some forty hands have been engaged in painting the iron girder work, and it is estimated that with this new plant a great saving will be effected.



WALLWORK AND WELLS' PAINTING MACHINE

NEW CANTILEVER BRIDGE AT PARIS.

For some years past the rapid decentralisation of the population of the city of Paris, due to the creation in its exterior quarters of thoroughly modern habitations for all classes, has created the necessity for more bridges to connect the right and left banks of the Seine, particularly between the industrial quarters of Grenelle-Javel and the purely residential quarters of Auteuil-Muette—small districts which count an increase of 14,000 inhabitants in a city whose population entire of 2½ millions in April, 1896, had only augmented by 87,000 in the same period of years, viz., 1891-1896.

The site chosen for the new bridge, which has just been completed, is between the bridge of Grenelle—so well known for the reproduction of "Liberty enlightening the World," erected on its mid-length—and the last, or high and low level, bridge at the fortification limits. Conjointly with the State, bearing half the costs, the Municipality decided to erect a bridge which would not be too greatly in arrear of modern practice.

As a matter of fact, out of the thirteen bridges existing before the construction of this one, from the Pont du Palais at the city centre to Auteuil, there are only five of iron: the light footbridge, Pont des Arts; the Pont St. Peres, composed of three arches of five hollow elliptical-section ribs, a structure of excessive resilience; the heavy cast iron Pont de Solferino, composed of three arches of nine massive girders each; the footbridge of Grenelle, supported upon round iron columns of large diameter; and finally the Pont de Grenelle, whose six iron arches are built into stone piers. The whole of the bridges are devoid of any elegance.

The Pont de Mirabeau, as the new bridge is called—for it connects the Rue Mirabeau of Auteuil to the Rue de la Convention at Grenelle—is composed of a central *volée* or river span of 100 m., and two half-spans or *culasses* of 36 m. each. The height to the middle of the central span is 8 m., or 25ft. 9in. above normal water level. Each half of this bridge is formed of seven frames of mild Longwy steel, poised upon the pier pivots, and slightly out of equilibrium so that the preponderance of the weight in the middle exerts a shoreward or *culée* pressure upon the piers. During the progress of the work the maintaining scaffoldings were removed entirely after assuring the balance by ballasting the shore span or *culasse*. The supporting cintre served successively for each side of the bridge.

The roadway measures 12 m. in width, and the footway pavements 4 m. each. On the right bank each pavement is placed in direct communication by means of stone stairways with the lower embankment, which is exceptionally wide at this part. The extremities of the frames are anchored down to the masonry of the embankment or *culée* by vertical rods, connecting their ends to bolts cemented into the stonework, so that the bridge may expand without lifting the frame ends or forcing the abutments.

The bridge was commenced April, 1894, at the Creil works of MM. Daydé and Pillé, and comprises about 2700 tons of metal put together by hand and hydraulic riveters. The iron employed comes from Denain and Anzin.

The masonry was commenced in May, 1893, by M. Letellier, public works contractor. The foundations of the piers rest on the solid chalk at a depth of 11 m. on the right bank, and 11·39 m. on the left, or, in other words, 16 m. below water level. The work throughout is done in Portland cement and rubble, excepting in the construction chamber, which is filled with hydraulic mortar or *béton*. The cap course is of Cherbourg granite. From the water level downwards the piers are bowed outwards, and have at their base an area of 28 m. in length by 10 m. in width.

Iron caissons enveloping the piers, having a working chamber of 2 m. in height and weighing 110 tons each, were employed in the building of the foundations. Four diving chambers were used for the entry and exit of the workmen and materials, air being supplied to them by four compressors installed on the right bank of the river. The first caisson was lodged on August 8th, 1893, and by October 24th the pier foundations of the right bank were finished and the first granite stone laid a day or two later. Without changing the positions of the air compressors, the work of the left pier was achieved in the same manner, the air pipes being carried on a cable 8 m. below the surface of the water, this latter pier occupying the three months, October to December, 1893.

The bridge was opened for regular vehicular traffic on April 20th, 1896. The first trials of the bridge were for dead weight; this was done by loading it with 800 tons of sand—400 kilos. per square metre — and finally, on April 19th, by passing over it twelve lorries, each loaded with 16 tons of stone and drawn by eight horses, representing a rolling load of about 200 tons. In both series of trials special apparatuses were employed for taking very elaborate indications of the flexions produced.

The piers of the bridge, though of themselves quite in keeping with the mechanical appearance of the bridge, are to be ornamented with four allegorical figures representing such subjects as Navigation, Commerce, Industry, and Science, modelled by the sculptor, Injalbert, and now being cast in bronze by Thiébaut Frères, of Paris.

The bridge was designed by M. Résal, chief engineer and professor at the school of Ponts et Chaussées, under the direction of M. Rabel, principal engineer, and carried out by M. Alby, engineer-in-charge.

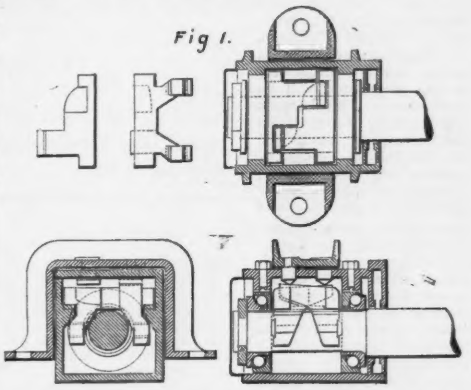
SIDE PRESSURE BALL BEARINGS.

The obstacle to the general adaptation of ball bearings to vehicles has been the difficulty of adjusting the pressure upon the races required to keep them in position, without on the one hand jamming the balls hard and fast between the ball races, or, on the other hand, leaving the balls so loose as to bunch and let the outer ball races slide down till they rest upon the cones. The methods hitherto used for "tempering" the races, either by Bown's ratchet nut and screw or by lock nuts and screws, are open to the objections that they put an unknown amount of side pressure upon the upper balls only, and that they require great skill and experience on the part of the manipulator.

Under these circumstances the ball races for vehicles of heavier proportions than the bicycle are necessarily of costly materials and workmanship, the slightest flaw occurring in a ball race which would check the course of the balls, leading inevitably to their being crushed as they are driven round the race by the momentum of the vehicle. The very finest and hardest quality of steel has to be used for ball races, which it takes long to cut by the hardest tools, and after hardening many of these costly productions are rejected for some apparently trifling flaw on the surface. Under these conditions the price of ball bearings for heavy vehicles has necessarily been prohibitive, and the danger of failure at a high speed causes a natural disinclination to incur risk as well as expense.

The automatic adjustment of the side pressure by bringing the weight of the vehicle to bear horizontally upon the ball races through the medium of a pair of bell-crank levers, it is claimed, not only overcomes those difficulties in the way of producing economical and workable ball bearings, but also distributes the pressure due to the weight of the vehicle more uniformly over the balls. The invention has already been adapted to the axle-boxes of tramway cars, the naves of carriages, and the hubs of cycles.

Fig 1.

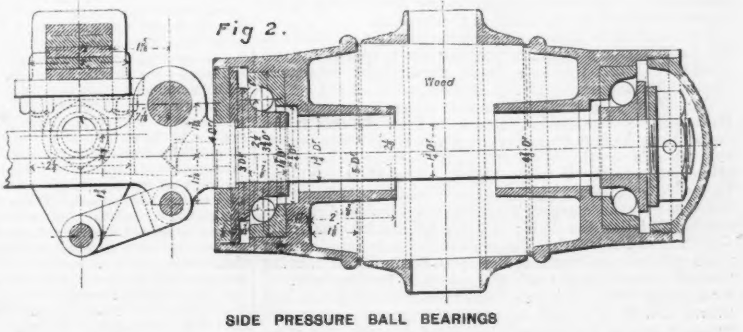


For railway and tramway car axle-boxes side-pressure ball bearings consist of two rings of balls in each axle-box, mounted at each end of the box between cones and ball races. The cones are free to move lengthwise on the journal, while the ball races move freely lengthwise in the ends of the box. The cones are checked by stops at each end of the journal, and the ball races are pressed outwards against the balls and cones by a pair of bell-crank levers bent at right angles, the horizontal arm of the lever carrying the weight of the car, while the vertical arm, which is forked to work over the journal, bears horizontally against the back of the ball race. The fulcrum of each bell-crank lever is a pair of knife-edges carried in the angles of a pair of brackets cast on the sides of the axle-box. Fig. 1 is the elevation, plan, and section of a tramway axle-box, as shown in the Exhibition at the Crystal Palace.

The application of side-pressure ball bearings to the naves of carriage wheels differs in mechanical detail from the axle box owing to the wheel rotating on the axle in the one case while, in the other, the axle rotates in an axle-box. The carriage wheel being free to move or press laterally, communicates the side-pressure from the one ball race to the other, so that a single bell-crank lever seated on the axle immediately within the nave communicates side-pressure from the weight of the carriage to the ball bearings, as shown on Fig. 2, which is a section of the nave for a dog-cart wheel.

In view of the probable demand for a practicable ball bearing for heavy automotor cars and horseless carriages, the Side-pressure Ball Bearings Syndicate's exhibit at the Crystal Palace attracts much attention. There is little doubt as to the advantage which would accrue in a competition of horseless carriages to the builder who successfully applies ball bearings to his carriage. These bearings are shown by the syndicate, whose offices are at 22, Walbrook.

Fig 2.



SIDE PRESSURE BALL BEARINGS

A Fast Yacht.—Mr. J. S. White, of Cowes, has just completed a new yacht, which is probably the fastest of her size afloat. She is named the Scud, and is owned by Mr. A. H. E. Wood, who formerly possessed the fine steam yacht Rona. The Scud is 85ft. long, with a beam of 10ft. 6in., and depth of 5ft. 10in., and on her steam trials developed a speed of 20¼ knots an hour, or 23½ statute miles. She has one propeller, the steering is on J. S. White's turnabout system, and her engines are of 530 indicated horsepower, the steam being generated in a Blechynden water-tube boiler. The pressure at the trials was 200 lb., not quite full pressure. The revolutions of the triple-expansion engines were 428 per minute. She has very much the appearance of a second-class torpedo boat, so far as her deck arrangements are concerned, and her bow and stern are of naval fashion. At the bow she carries a powerful electric search-light. She is beautifully fitted below. The saloon and state-room are aft, fitted with the electric light, and upholstered in royal blue and golden yellow. The crew are berthed forward. Running at over 20 knots there was hardly any vibration. The vessel has commanded a good deal of interest amongst the yachting fraternity in the Solent.

RAILWAY SCHEMES IN THE HIGHLANDS.—SESSION 1896.

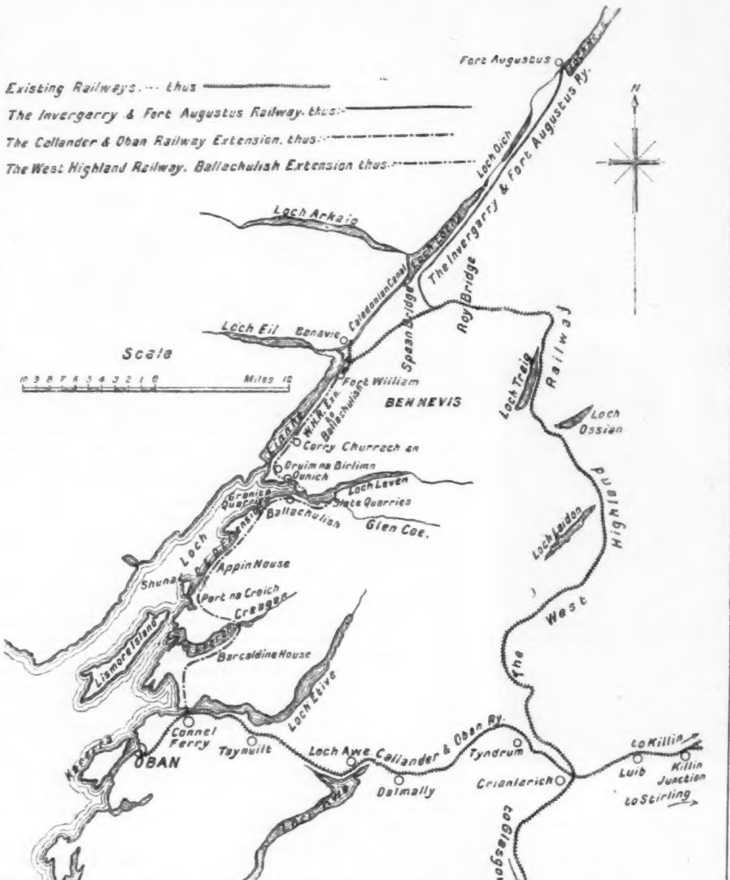
Some time ago—The Engineer, December 20th, 1895—we placed before our readers a *résumé* of the Private Bills deposited for the present session of Parliament. Since then we dwelt in some detail on the Ayrshire group of projected lines, giving the more salient features of each proposal, and accompanying our remarks by a map showing each of the rival routes—The Engineer, February 22nd, 1896—and we now propose concluding our remarks on the subject by similarly describing the Highland schemes, and briefly alluding to the more interesting features of each :—

The Invergarry and Fort Augustus Railway.—This line commences near Spean Bridge on the West Highland Railway, and running in a westerly direction, bends northwards till the shores of Loch Lochy are reached. The route then follows the loch, and skirting the southern shores of Loch Oich for their entire length, spans the Caledonian Canal near Fort Augustus, terminating at the southern extremity of Loch Ness, where a substantial timber pier will be formed. The line, which will be a single one throughout its entire length of twenty-four miles, is estimated at £6000 per mile, or some £150,000 for the entire scheme. The principal works of engineering interest involved will be the swing bridge over the Caledonian Canal, near Fort Augustus, and the viaduct over the river Spean at the other end of the line. No tunnels occur along the route, and no difficulties of any magnitude will be encountered. The sharpest curve will be one of twelve chains, whilst 1 in 62 will be the ruling gradient. Stations will be erected at suitable intervals, and every provision made for the transport of sheep, a class of traffic from which considerable revenue is anticipated. The beauty of the scenery is too well known to need special comment at our hands, though in this connection it may be pointed out that during the season tourists will avail themselves of the proposed route in very considerable numbers. The landowners along the route, who are also the promoters, are favourable to the scheme, and the engineers are Messrs. Formans and McCall, C.E., of Glasgow.

The Callander and Oban Railway ; Ballachulish extension.—The Callander and Oban Railway Company's proposed extension to Ballachulish starts from the company's existing line near Connel Ferry, crosses Loch Etive by a fixed bridge of a single span of 500ft., with a clear headway of 50ft. above high water, and running northwards, sweeps past Barcaldine House—a seat of the Camerons—and crosses Loch Crenan at Creagan in three spans each of 100ft. and two spans each of 60ft., all of which are 40ft. above high water. The proposed line then turns westward, and running through the Strath of Appin, passes Portnacroich, thence following the coast line very closely, it reaches Appin House, and finally terminates at Ballachulish with a branch eastwards to the famous slate quarries of the district at the entrance to Glen Coe.

The length of the undertaking is some twenty-five miles, and the parliamentary estimate provides for a cost of £10,000 a mile. The line will be a single one throughout its entire length. The engineer is Mr. Wolfe Barry, C.B., F.R.S.

The West Highland Railway Company's extension to Ballachulish.—The halfway attock on Fort William by the Callander and Oban Company—just described—is to be met by proposals by the West Highland Railway Company to extend its system to Ballachulish. The West Highland Railway's extension will commence at Fort William by junction with the company's existing main line, and running south, will follow the shores of Loch Linnhe for practically the whole of its length. Passing Corrychurrachan, the new route will curve eastwards at Druim-na-Birlimn, and, running through Ounich, will reach Ballachulish, its terminus. A road bridge over Loch Leven forms part of the proposals, and across this it is sought to carry a tramway, one branch running east to the Ballachulish slate quarries, the other west to the granite quarries on the shore of Loch Linnhe. The total length of the undertaking is twelve miles, and a parliamentary estimate of about £9000 per mile has been put in. The principal feature of the undertaking is the bridge at Ballachulish, consisting of three fixed spans of 144ft. each, and two swing spans each of 90ft., the whole being 8ft. above high-water level. The engineers are Messrs. Formans and McCall, C.E., of Glasgow. It only remains to be added that the line presents no features of difficulty in construction, the gradients are easy, and twelve-chain curves are the sharpest necessary. The line will be laid with 80 lb. steel rails, and in every respect will be a first-class one.



HIGHLAND RAILWAY SCHEMES

The Sanitary Institute.—The council have accepted an invitation from the city and county of Newcastle-on-Tyne to hold a Sanitary Congress and Health Exhibition in that city in the autumn of this year.

Brussels International Exhibition, 1897.—The Department of Science and Art has received, through the Foreign-office, a copy of a Belgian Decree applying Article XI. of the Convention concluded in Paris on the 20th March, 1883, for the protection of industrial property, to the goods, &c., that may be sent to the Brussels International Exhibition which is to take place next year.

THE "JAMES FORREST" LECTURE.

"PHYSICAL EXPERIMENT IN RELATION TO ENGINEERING."

By Dr. Alexander Blackie William Kennedy, F.R.S., M. Inst. C.E.

It has been the expressed wish of the gentleman in whose honour the "James Forrest" lectures have been instituted, that they should deal with the relation of various sciences to our own profession. To those of us—and they are many—who have long enjoyed his friendship, and who are to some extent familiar with the extent to which our profession is in his debt in matters innumerable, it is practically a duty to meet his wishes in such a matter. But it must be acknowledged that the duty—as regards the lecturer—must grow every year more difficult, as the field becomes limited by his predecessors ; and even at present it was with no little nervousness as to the selection of a subject that I accepted last year the invitation to give this lecture in 1896.

There is perhaps no science, except those in the biological group, of which it might not be argued, with some degree of plausibility and reasonability, that the profession to which we all belong was a direct application. The sciences of mathematics and of physics, of chemistry and of geology, concern themselves with the exact statement of the nature and relations of facts and phenomena with which we as engineers have continually to concern ourselves. But the point of view of the purely scientific investigator and of the engineer, in regard to these facts and phenomena, are no doubt very different. In rare and exceptional cases, one man can play both *rôles*, but this happens so very seldom that for all practical purposes they may be regarded as distinct from each other. And no one who is not terribly narrow—on one side or the other—would deny that either might form a worthy life-work for any man, however high his aims or ambition.

I excepted just now the biological sciences from those with which engineers were directly in touch. But, in spite of this, I confess that I have had a great wish for years past to devote some time to the working out of a theory of evolution in relation to engineering progress. I cannot help thinking that there is something in relation to things inorganic which closely resembles the position of natural selection in the organic world. The struggle for existence, which too obviously exists among engineers themselves regarded as organic beings, seems also to exist in effect among engineering productions. There is also among them a survival of the fittest, and the laws which determine what is the fittest at any time, and how the standard of fitness alters as time goes on, are probably capable of fairly exact statement—in correlation with the laws of general human progress—at any rate they are very well worthy of examination. This biologico-engineering investigation would be no doubt rendered more difficult by the fact that artificial selection continually comes in to help and accelerate, or it may be to hamper and impede, but in any case to modify, the inorganic equivalent of natural selection. I have found this whole subject a most tempting one, full of fascination, and to some extent also of surprises. But finally I felt constrained to leave it, at least as far as this lecture is concerned, to someone—some fortunate person—whose mind was not so overcrowded with the innumerable details of every-day work as my own, or who was able, in spite of these details, to obtain at the same time a broad and comprehensive view of the whole subject from a point higher and more commanding than any that I seemed able to attain to. I hope that in some future year I may have the pleasure of listening to a "James Forrest" lecture in which "Evolution in Engineering" may be adequately dealt with. For myself, I have found it necessary to be content with a much more limited subject, although one perhaps on which my own work gives me more right to speak, "Physical Experiment in Relation to Engineering."

We are all at this present time so familiar with the idea of physical laboratories—places in which physical experiment is carried out systematically and continuously, both for purposes of scientific investigation and of education—that it is hard to realise how very modern an institution the physical laboratory is. Until quite lately the most distinguished investigators worked in laboratories which they had made for themselves and which were essentially their own private studies. The Royal Institution laboratories—originally, I think, rather chemical than physical in conception—nevertheless became to a great extent physical, and in this way were early and notable extensions of the purely private laboratory, and happily exist still to furnish admirable physical work. But it is practically only within the last thirty years that physical laboratories, as we know them to-day, have come into existence. Thanks very much to this growth of experimental and physical teaching, we have now an army of trained physical investigators distributed all over the country, whose principal occupation—besides teaching—is the making of researches in experimental physics, and in this way contributing to our knowledge of the phenomena of the world around us, the phenomena which it is our business to turn to the "use and convenience of man." Not only this, but within the last twenty years there have come into existence numerous well-equipped engineering laboratories in connection with our technical colleges and schools. These engineering laboratories are, of course, simply physical laboratories modified in a certain special direction for our special purposes, and the investigations carried on in them are of the nature of physical experiment as fully and completely as those which are carried out in physical laboratories proper. The aim and scope of the two classes of experiment, however, differ considerably, as do their relations to our own work, and it will be my object this evening to put before you what, according to my own view, are the relations between these classes of experiment, and especially between each class and our own work. I need hardly say that I am bound to look at the whole matter throughout from the point of view of the engineer. I do not for a moment pretend that I am capable of taking up the position of the physicist, and of course I keep in mind also that I have to speak to an audience consisting essentially of engineers, and not of physicists.

Physical experiment, so far as it has relation to our own profession, may fairly be considered to serve three distinct purposes. In the first place, from the purely academic or educational point of view, it is most important and helpful in the training of engineering students. (And it is well to remember that although a great many of us never were engineering students, nor had any opportunity of obtaining such training, yet the most conservative must now recognise that in the future our sons and successors must look on the student stage as being as essential as the pupilage or the apprenticeship.) Then, secondly, what may be called purely physical experiment is necessary to supply us with most of our most important constants, whether connected with the thermal properties of steam, the electromotive force of a Clark cell, the density of water, the elasticity of steel, the coefficient for a *vena contracta*, or a thousand other matters of similar nature. Lastly, technical experiments, which are essentially physical experiments, but of a much more complex nature than those of the physical laboratory—although not on that account more difficult to carry out—are necessary for determining many matters ; such, for example, as the efficiency of a dynamo, the steam consumption of an engine, the flow of a river, the resistance of a ship, or even the deflection of a girder under a moving load.

Let us consider, in the first place, the purely educative or academic type of experiment. Here the first requirement is the very simple one—which indeed may be served by an endless variety of experiments, extending far beyond the limit of Physics—that the student should learn first to see and to measure, and then to write down what he has seen and measured. (Anyone who has had to do with laboratory work knows very well how necessary it is to differentiate in this fashion.) The experiments require to be, as far as possible, quantitative rather than merely qualitative ; but, otherwise, the simpler they are the better. It is unnecessary here to go into any details about them, but with a view to emphasising their importance, it is worth while just to look for a moment at the sort of thing by which, in actual engineering work, these simple experiments may be said to be represented. Perhaps those whose work lies greatly in experimentation, like my own, know best how very hard it is to find assistants, unless they have been trained in a laboratory, who can be trusted at first even to take quarter-hourly readings of a steam gauge or a counter, or any such duty, ridiculously simple and easy as it appears. To ask an untrained man to count the revolutions of an engine which has no continuous counter attached, or to read the dials of an ampère-hour meter, at exactly regular intervals of time, is merely to court disaster. The story is familiar of how Robert Houdin had so trained his faculty of general observation, that one look at a shop window would impress its contents on his mind more vividly and accurately than ten minutes of hard looking would do in the case of an ordinary man. It is really just the same with the simplest of our observations. The ordinary mind does not naturally and at once see, and see accurately, the simplest thing that is before the eyes. One has to look, to exercise conscious mental effort, as well as merely to see, and we all of us require to be taught how to look, even in these most simple matters. And when the enforced looking has to be done at exactly a particular time and no other, the average mind is apt to find the whole process an intolerable burden, all the more because it is inclined to despise the work as being too childishly easy for consideration at the very time when it is failing to carry it out!

So far as concerns the training of the faculties of observation at the stage of which I am speaking, probably chemical experiments would serve as well as physical. In certain respects possibly they might even be better, but with this we need not now concern ourselves. An important point is, perhaps, that in their earlier stages the student should not be allowed in any way to get the notion that his experiments are more than mere rough exercises. Any standard of accuracy which he can possibly attain is comparatively a very low one, and by the nature of the case the experiments he can do must be simplified down enormously before they can be put into his hands, so that at best he is only making a rough determination of one element in an artificially simplified operation, the full conditions of which he is not even in any position to understand. The actual figures which are obtained by him can under no circumstances be regarded as having any intrinsic value ; and one of the difficulties of the case is, no doubt, to persuade the student to exercise his highest degree of care in obtaining results which at the same time he is told, or knows, are of no use whatever. The engineering student, I am sorry to say, is generally a terrible utilitarian. The unhappy professor has to enter into all kinds of subterfuges to get him to take an interest in, or do any careful work at, matters which the omniscience of youth has once pronounced to be "useless." Later on, of course, he is wiser and a trifle less narrow-minded ; but I suppose the stage of first yearness is one through which all of us have to pass in one fashion or another, to the grief of our pastors and masters, and to our own later regret.

More interesting to most of us, perhaps, than this purely academic matter is the consideration of physical experiment under the last two headings which I have mentioned.

From among these comes experiment which really belongs to pure physics, but in which we engineers may claim to be as much, or even more, concerned than the physicists, although both the difficulty and the honour of the experiment must fall to them. I suggest that we are even more concerned than the workers in pure science for two reasons, of which the first is that the whole of our interest is practically concentrated on what constitutes only a small part of the boundless region open to the physicist. He can spread his affections over glass and sealing-wax, and let them roam from ice to iron. We have only one love, or at any rate never stray very far from a limited number of matters which concern what I have heard contemptuously called "technical materials." He interests himself legitimately and equally in argon and carbon, in steam and in ethyl-alcohol ; he loves to extend his thermal conditions so as to get liquid air or gaseous carbon. We, on the other hand, are compelled to deal with a very small number of materials, and with these materials only in states in which we can readily obtain them. In fact, as every one knows, nineteen-twentieths of our liquid and gas problems affect only liquid and gaseous—or vaporous—water, and only the remaining small percentage is left to be distributed between coal-gas and producer-gas, liquid carbonic acid and anhydrous ammonia, and so forth. So far as the more or less "permanent" gases are considered, our interest is throughout perhaps rather chemical than physical.

Then, again, we may claim to have a first interest in certain physical results, because of the extraordinary frequency with which we have somehow or other actually to make use of them—I mean a real live use, and not merely a use in an examination question, or in a text-book or a lecture. Not only would our whole work become mere guess work without the knowledge of these results, but, having this knowledge, we are compelled by the very nature of our work to make such continual use of it that probably we are much more familiar both with the figures concerned and with the phenomena which they represent, than even the men to whose magnificent accuracy and unlimited diligence we owe their original investigation and determination. I mean, of course, such results as refer to the thermal relations of water and steam, to the calorimetry of fuels generally, to many hydrodynamic problems, to most problems in elasticity and what is clumsily called the strength of materials, to frictional questions, to innumerable problems relating to electrical matters, and certainly to an enormous number of matters bearing on mechanics, which, of course, is to be considered as a branch of physics.

I feel so strongly this sense of our paramount interest in certain physical problems that I have not hesitated sometimes to resent the way in which physical writers and speakers are occasionally inclined to instruct us how to express our ideas, for example, as to mass and weight, and sundry vital matters of that kind. I really think that people who have to deal with these matters as much, as often, and as thoroughly as we have, and who are on the whole reasonably competent beings, may be assumed to know how best to manage our own affairs in these respects. Mechanics are to us the breath of our nostrils, and not a mere vehicle for examination papers; and it should be remembered that the requirements of the latter case may be very different from those of what I may venture to call "real life." I feel some satisfaction in remembering that the only fatal case of a misused "g" that I can call to mind was on the part of a physicist, whom we all admire none the less for the way in which he scolds us, but who in the very act of showing us the way we ought to use that symbol, proved conclusively that all submarine cables would break by their own tension while lying on the sea bottom! It would perhaps be hardly proper, or even safe, that I should here say anything, as I am much tempted to do, as to the vexed question of units, which from time to time seems to agitate many minds. Let me only suggest that, on the whole, it does not seem to me that the people who would be most affected by the change are at present those who are most anxious for it. In fact, admitting certainly a few notable and very distinguished exceptions, it really seems as if engineers in general were content to go on in their own way, unconscious of the terrible pitfalls and difficulties by which it is understood that they are surrounded on all hands. I quite admit, of course, that it by no means follows that the pitfalls do not exist, although I confess to being somewhat sceptical about their reality.

But having spoken so strongly of engineers as being the users of certain physical results, I must look at the other side of the matter. We engineers may have, as I urge, more interest in these matters than anyone else, but it is certainly true that we have not ourselves to thank for the determination of the results which we require and which we make so much use of. For practically the whole of these results—results without which, as I have said, our profession would hardly exist, would at best be a mere trade instead of, as we are proud to consider it, a scientific profession—we are indebted to workers in physical science pure and simple, men without the least taint or suspicion of technical or utilitarian intent.[*] It would therefore ill become us engineers if we were to say or do anything which should, even in the most indirect fashion, tend to belittle the work of pure physicists, on which every day shows us more how much we are dependent. Our gratitude is so real and so deeply seated that we need not, and do not, even resent the expression of regret which has sometimes been heard from a discoverer, that what he has done should be of any use whatever.

A physical experiment such as is necessary for the determination of any one of the physical constants which we have in continual use differs very essentially from such physical experiments as we engineers have to carry out in the course of our own work. It is at once much simpler and much more difficult. It is simpler because its object is the solution of one certain problem, which has been by much care and pains isolated from all its surroundings, from all related and, so to speak, adjacent problems. The first work of the physicist, dealing with his problem, is in fact to find out a way of so isolating his question that its solution may give him exactly the one quantity he wishes to know and no other. Of problems of this kind I confess I speak as an outsider, but as an outsider it has been to me often a matter of the greatest interest and even wonderment to see what enormous pains a physicist takes, and must necessarily take, to make sure that he is measuring exactly the thing he wishes to measure—that thing, that whole thing, and nothing but that thing; to see also what innumerable precautions he has to take to ensure the absence of minute errors, or to find out where any such errors might occur and whether they have occurred, and to evaluate them if they are unavoidable. I have found, too, that in such cases suggestions derived from my own experience in engineering experiment have been often received with a coldness which I am afraid was no more than they may have deserved. For, as I shall endeavour to show, the conditions under which experiments of this kind have to be made are absolutely different, both as to aim and method, from those of the experiments—more technical if not less physical—which we have to carry out for ourselves in our own work.

In a physical experiment of the second category, such as those of which I have been speaking, the primary points may be said to be, first, that the object of the experiment should be single, definite, isolated, separable and separated from all surroundings; secondly, that it should be general in its nature, and should not relate merely to one special case; next, that as a problem it should be capable of exact determination; and lastly, that the final result should be as nearly absolutely accurate as it is possible for any physical determination to be. Take as examples such matters as the determination of the density of steam, of the variation of the specific heat of water with change of temperature, of the calorific value of pure carbon, or of the mechanical equivalent of heat. Such problems properly stated admit each of one exact solution, one answer which is absolutely right, even in the mathematical sense of that phrase. It is the highest object of the physicist, in dealing with such a problem, to obtain the right solution. He spares no pains to obtain it, he determines each minute correction with the patience and care of a man who knows that the value of his whole work may be vitiated by a single overlooked source of error, even of the smallest magnitude. We engineers are possibly in some danger of forgetting occasionally, in view of the familiarity and matter-of-courseness of certain figures with which we have frequently to deal, that just these every-day and familiar numbers, on account of their very importance, were those which required and obtained for their determination the most careful, exhaustive, and accurate experimentation in the hands of the most experienced physicists.

After speaking in this fashion of the nature of experiments in pure physics, it may sound at first absurd, but it is nevertheless true, to say that physical experiments in the third category—the technical experiments which we engineers have so often actually to carry out—do not fall under a single one of the conditions which I have just given as characteristic of experiments in pure physics. We cannot, even under the most favourable circumstances, put before ourselves exact and isolated problems; we have much more often to deal with special than with general cases; we cannot choose problems which are capable of finally exact solution; and therefore, lastly, we should treat the matter entirely wrongly if we attempted to obtain more than a certain limited degree of accuracy in our solution—an accuracy very limited indeed when compared with the all but mathematical accuracy with which problems in pure physics can be solved.

The conditions under which engineers have to carry out physical experiments, of course, vary very greatly. In certain simple cases they are essentially physical investigations, be it in connection with friction, with elasticity, or what not, which at first sight do not greatly differ from the experiments which I have just discussed. There is probably, however, more difference than appears at first sight, although the spirit in which both sets of experiments have to be made is the same. Take, as an example, the determination of the elastic modulus—or the specific extension—of a piece of steel. Probably, with very perfect instruments and with extreme care in manipulation, a value of the modulus could be obtained which should be accurate, say within 1 in 2000, for that particular piece of steel. But a figure so obtained would not be accurate even for other pieces of steel made at the same time, and out of the same ingot as the one experimented on; while, of course, there is no one absolute value for the modulus of elasticity of the widely-differing material, of which all sorts go by the name of steel. Under such conditions—and I have chosen a particularly favourable example—it would be mere affectation, and, in addition, would be actually misleading, to claim anything like physical accuracy for our results. Indeed, I must go further and say that the truly scientific way of treating an experiment in engineering physics is to recognise from the outset its limitations as to accuracy, and to be careful not to state a final result in a form which should lead to the supposition of any greater degree of accuracy than that which the conditions of the work can actually allow.

The difference between physical and technical experiments may easily be illustrated by another example from the region of elasticity. The determination of the deflection of a beam, transversely loaded, as a physical experiment would resolve itself into the test of the behaviour of a piece of homogeneous material, preferably of the simplest possible cross-section, probably rectangular. It would be a matter of importance to ensure that the material was exactly of a certain chemical nature, and that it was mechanically free even from the slightest defects; it would also have to be machined to certain exact dimensions. Even with every care, the almost unavoidable imperfection in the material, minute variations in uniformity of structure, and so on, would be very difficult to deal with and to allow for. As a technical experiment, on the other hand, the beam might consist of plate, and angle iron secured together by rivets, the whole forming a structure with absolutely no pretence to homogeneity, nor to absolute exactness of dimension. Its rough surface would be carefully left intact, and not in any way machined, its riveted parts would be brought together as well as was reasonably possible with the appliances at the command of the engineer, but without any attempt to make a special fit between surfaces. In fact, the whole thing would be constructed in imitation of the way in which a riveted beam, such as is used as a girder, is usually made. The result obtained would obviously not be a general one applicable to steel as a material, or to beams as geometrical forms, because the data of the problem, even the dimensions of the beam itself, could not be determined with minute accuracy, nor would the actual final result be comparable in accuracy with the determination of the similar problem treated from the purely physical point of view. Hence, as the experimenter cannot for a moment pretend, and should not for a moment delude himself into supposing, that his results could be more accurate than his data, it is his first duty in this line of work to find out within what limits of accuracy his experiment can be carried out, and, when he has obtained his results, to state it only within these limits. Under these conditions the statement of a result in round figures is often much more accurate than its statement down to the last decimal place which appears in the arithmetic. I have heard it said by some of the students of the greatest of our physicists, Lord Kelvin, that this was a point upon which, even in a great deal of purely physical work, their master always insisted most strongly. But I am afraid that it must be admitted, as a weakness of much of our engineering experimentation, that its results are given in figures which are absolutely ludicrous as indicating the value of the quantities actually measured. In these matters, perhaps, our friends in America are even worse than we are, and those of us who have anything to do with steam vessels or with steamship trials, are perhaps the worst sinners. I suppose no physical problem could very well be much more complicated than that—I ought rather to say those—involved in the carrying out of a marine engine trial at sea, especially when power and speed are both concerned. When it is considered that the final result depends on the accuracy of our knowledge of the dimensions of the steam engine itself, and of the steam engine indicators, on the uniformity of elasticity and proper scale of the indicator springs, the accuracy with which the revolutions are observed, the accuracy of timing on the mile and of observing the distance at the same time, to say nothing of the assumption that the indicators themselves and their gear, unlike every other thing in the universe, are entirely devoid of hysteresis, it will be seen how entirely out of the question it is that the figures obtained, even for a single run in one direction, should admit of statement in, say, more than three figures. When to this is added the uncertainty of the method of averaging speed as between a number of runs under different conditions as to tide and wind, the matter becomes still more striking. Or, when coal and water are also to be measured, and the weighing or measuring of both, and the calibration of all the heavy apparatus used for the purpose, as well as the personal errors due to making observations of large quantities under awkward physical conditions, in a minimum of time and in the worst of atmospheres, are considered, the uselessness, and, indeed, the absolute inaccuracy of extremely minute figures, become absolutely glaring. It is sometimes useful, no doubt, under these conditions, to work out results to four significant figures for the sake of mere arithmetical checking; but no one who has had anything to do with the matter would suppose for a moment that more than three figures were of the least importance, and the statement of results of observations in five or six figures merely causes the enemy to scoff. Let me again say here that I am not suggesting, and I do not think, that an experiment of a technical nature is unscientific because its result is only capable of expression within one or two per cent. instead of within one or two hundredths per cent. I wish only to urge very strongly that in a really scientific spirit such an experiment must be undertaken only with a distinct recognition of its limitations, and of the limitations of accuracy of result such as I have roughly indicated.

But I must claim for technical experiment that it is truly scientific work if only it be conducted with full recognition of its conditions and limitations, and not as if it were a laboratory experiment badly done—a mistake which I fear is too often made. Let it be recognised first of all that our object is generally the determination of certain facts, or quantities, or ratios, which are to be found under certain very complex conditions. As I have elsewhere said, the duty of the engineer is to recognise these conditions and deliberately to include certain of them in his experiment. The physicist has to spend much thought and trouble on the modification of conditions, which are disturbing elements in his work. All conditions which might modify his main result, or which might make it difficult for another experimenter to obtain precisely the same value for the quantity looked for, have to be either eliminated or evaluated. The conditions are his enemies, in fact. Otherwise with us, the conditions in general form part of our problem, and for many purposes the reduction of the experiment to its lowest terms, which is the object of the physicist, would not only be impossible, but would, if it could be done, make the result quite useless to us.

The determination of the efficiency of a steam engine is, of course, a very common piece of work, and may serve as an illustration of the two different ways of approaching such a matter in connection with this question of conditions. From the physical point of view, I imagine it would be best to endeavour to reproduce the working of the much-abused Carnot cycle.[†] If this were absolutely successful it would merely give us a result which would agree with those which we can already calculate from the physical data which are in our possession, and this result would add nothing to our present knowledge, nor would it give any additional help to the designer of steam engines.[‡] But it would, if it could be carried out, be an experiment strictly physical, and following in the lines of, for instance, Joule's classical experiment on the mechanical equivalent of heat. The engineer, on the other hand, who has to work at the same problem, has to deal with it in the fashion in which it is now handled in so many engineering laboratories. He has to make himself an actual engine, in which the normal conditions of engine working—as to loss of heat by conduction, condensation, radiation, and so on—are, or can be, reproduced, and he has to make his experiments on this machine, and as nearly as possible under conditions resembling those under which engines normally do work. Then one by one certain of the conditions may be altered, so that some estimation may be made of the effect of each. So may be obtained figures as the result of *bonâ fide* technico-physical experiment, which are also in a form more or less directly applicable to engineering work.

I have just mentioned the variation of conditions one by one. This is hardly a matter which I need insist on. It is of great importance even in a physical experiment, where all the conditions are simplified to the last extent; but in a technical experiment, where the conditions themselves are very complex and often not easy to grasp, it is obviously vital. It is no doubt one of the great difficulties of all technical experiment to find out exactly what the conditions are, and it may in many cases need more experience and more care to determine and define the actual conditions than it does to carry out the measurements involved in the experiment. This is a matter which will be recognised by every one who has had to do with work of this kind, but about which probably it is unnecessary to say more here. Bearing on it, however, is a matter which may fairly be mentioned, namely, the combining of the results of several technical experiments. This is often very tempting, but is always very difficult. A simple case is, for instance, the determination of the efficiency and of the economy of a steam engine. A certain experiment may show a certain maximum efficiency; another experiment, on a more or less similar machine, but carried out at another time, may show a maximum economy. Naturally there is a strong temptation to state both maxima as belonging to the machine tested. It is no doubt possible that they may do so; but, on the other hand, without the most minute knowledge of the circumstances of the case, it is quite unsafe to assume that they do, and in this respect the difference between the general character of purely physical work and the special character of technical experiment comes into clear relief.

In fact it is much more difficult to handle rightly the results of engineering experiment when they have been determined than those of pure physics. It is by no means always, or obviously, easy to apply these last, at least one has known very ludicrous mistakes to occur through their misapplication. For instance, I have seen elaborate calculations based on the determination of the weight of steam used by an engine from the pressures shown by an indicator card and the measured dimensions of the engine; and quite recently I was confronted with certain supposed phenomena, which rested entirely on the assumption that a vessel of certain dimensions actually received from a steam-pipe suddenly opened to it only the weight of steam corresponding to its volume and its pressure shown by a gauge. In both cases the troublesome phenomena of condensation were entirely left out of account, and the result of a purely physical determination was applied to a technical problem with very disastrous results. But it is infinitely more difficult often to interpret and to apply the results of our own experiments. For instance, let it be found that one boiler, engine, and dynamo together require the consumption of so many pounds of coal per electrical unit, how much coal per unit will another boiler, engine, and dynamo require? Put baldly into this form the question sounds ridiculous. But after all, is it any more absurd than our constant endeavour—that is, before the days of the present development of engineering experiment—to arrive at similar comparative conclusions from the, doubtless unimpeachable, figures of an engineering pocket-book? I am sure there must be many of us who can still recollect how painfully we endeavour to make the statements of Molesworth furnish us with an answer to our own problems, and how entirely we failed to get things to fit in. I do not suggest that the fault lay with the pocket book; the fault lay in the endeavour to correlate figures and results which in no way belonged to each other, which represented the result of experiments made under conditions quite unknown to us, but certainly varying from each other, and no less from the conditions—possibly also unknown to us—of the problem we actually were trying to work out. I dare say that many of us who have been hungry and thirsty for facts and figures during most of our lives, remember very well the joy with which, at a certain stage, we put down in our note-books any kind of experimental results of which we could hear, or of which we could obtain possession by any means, whether they related to steam engine trials, or to girder tests, or to the discharge over weirs—I do not say to dynamo trials, because there were no dynamos in those days! And I am sure that all of us must have suffered pain and disappointment later on when we found how extremely difficult it was to make any use of the much-valued figures that filled our pages—they would never, somehow or other, seem to tell us just what we wanted; there was always something about them which eluded us, one particular matter of vital importance in the data, or in the result, of which we had no memorandum. The fact is that it is always extremely difficult to apply accurately the results of experiments made by others, however carefully made and however accurately described. To realise this, even in reference to purely physical work, one need only see how many pages in the "Philosophical Transactions" are sometimes necessary to describe the methods and precautions involved in a determination which has not one-tenth the complexity of such matters as we are compelled constantly to try to measure.

To anyone who wishes to realise to the full the difficulty of dealing with, or applying, the very simplest kind of experimental result, I recommend the maddening task, so often lightly spoken of by those who have not tried it, of calibrating indicator springs, and then trying to apply the results to the correction of the corresponding indicator diagrams.

The fact is that no one can usefully apply physical results who has not himself studied the methods by which these results are obtained, either by the royal road of work in a physical or technical laboratory, or by the hard and up-hill method of self-education in the making of technical experiment, without the advantage of the preliminary training which I have mentioned earlier; and hence the importance of the knowledge of how to make accurate observations, which I have insisted upon as a thing quite apart from the knowledge of the actual figures to be obtained by such observations. It would perhaps be cruel to say that no one can usefully apply physical results who has not studied the methods by

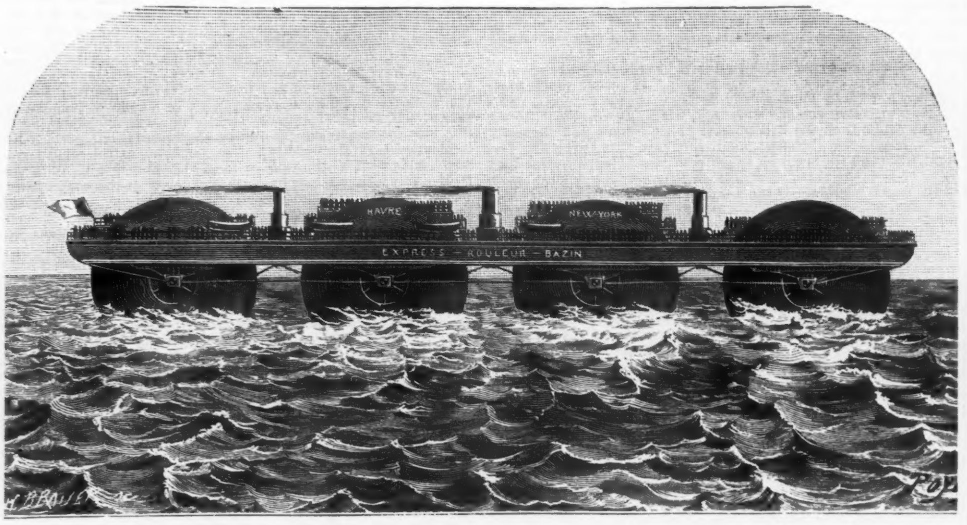
---

[*] I think probably the only notable exception to be made in this matte, is in regard to scientific experiments relating to strength and elasticityr some of which have been made by engineers and with a more or less definitely technical intention. But probably such men as Bauschinger, Martens, and Tetmajer, are to be considered essentially as in the position of physical workers.

[†] I need hardly say that I do not for a moment suggest that any physicist would wish to obtain experimentally a result for which he has already given us all the constants, and which we can therefore completely obtain by calculation based on physical results already before us.

[‡] I do not wish here to be understood in the least as sharing that great objection to the Carnot cycle which I know fills the breasts of some of my friends. It appears to me that it would be just as reasonable to object to the asymptote of a hyperbola or to the line at infinity! We require these limiting cases, and should get on very badly without them, and I am not inclined to say that they are useless—indeed, I think they are extremely useful—although I am perfectly conscious that they represent a state of affairs which is technically, and even physically, unattainable.

THE BAZIN WHEEL STEAMBOAT

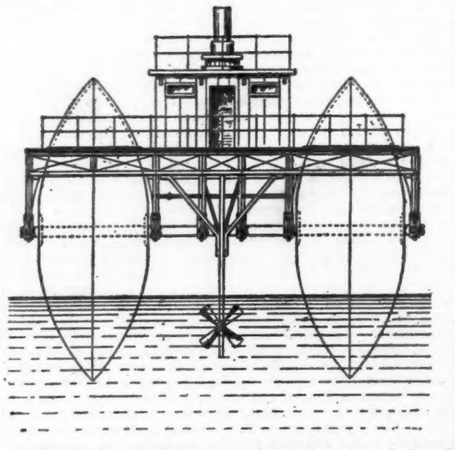


which they are obtained, were it not that nowadays the possibility of such study is open to everybody. One may therefore state the truth in this matter without the fear of making anyone unhappy. I do not know whether I should be far wrong in suggesting that a certain amount, perhaps a great deal, of the very rapid improvement which has taken place in late years in engineering practice in respect to efficiency in the working of machinery, economy in the production of energy, and economy also in the use of material, has been due directly or indirectly, or both, to the growth of the habit and knowledge of experiment among the present generation of engineers. No one who is familiar with the progress in such matters as I have this evening dealt with, during the last twenty years, and has noted the extraordinary development which has taken place, can fail to be struck with it. No doubt a considerable part of this development has been due to the better education generally of engineers, and particularly to the great extension of engineering literature, in which undoubtedly the engineering newspapers have played a most honourable and important part. But these general causes in themselves would not, I believe, have been sufficient if it had not been for the contemporaneous development of what I may venture to call experimental training, accompanied by a demand on all hands from inventors, manufacturers, and even from the public, for reasonably exact numerical statements in relation to everything which can be measured, instead of the vague generalities which used to pass muster as critical examination of the advantages and disadvantages of any new proposals.

I hope I need not say here that I quite recognise that an engineer's life is not made of experimentation, and that the work of *doing* is even higher than that of *measuring*, at least from our point of view. But in dealing with my subject of to-night, I am, of course, bound to take up and emphasise this aspect of engineering work. I hope that it may be considered that I have been able to justify my choice of a subject which at first might appear so limited, but which in reality I believe so important, as that to which I have addressed myself this evening — the relation of physical experiment to engineering.

THE BAZIN DISC WHEEL STEAMBOAT.

CURIOUSLY enough interest is being taken by French marine engineers in an experimental vessel now being constructed at the Saint-Denis Works of the Cail Company for a concern which was formed some time ago to work a so-called new system of propulsion of M. Ernest Bazin. It is hoped that this novel boat, which has already been in hand six months, will be launched in July next, and it will make its first trial trip across the Channel as soon after that date as possible. Writing on this subject our Paris correspondent says:—"Though at one time the *navire rouleur*, as it is called in France, met with a great deal of criticism among marine experts, who were rather sceptical as to the success of this new departure from the generally accepted ideas of naval design, it is significant that a fuller acquaintance of the theory laid down by M. Bazin has led them to place faith in the capabilities of the disc wheel vessel. This theory is by no means a new one with M. Bazin, who has been working at it for twelve years or more, and an inspection of the models to be seen at his works at Levallois shows that the system has been applied in a great many different ways before the inventor was able to evolve the remarkable vessel which is now to be put to a practical test. It may be said that the first idea of M. Bazin was to apply a revolving motion to the vessel for the driving action in order to overcome the enormous waste of power due to the resistance of the water and the friction. As is well known, this resistance is proportional to the square of the speed of the vessel, and as the ratio of horse-power necessary to drive a ship increases enormously with the high speeds sought to be obtained, it is believed that the limit in the keel boats has almost been reached. In the problem which he has set himself to solve, M. Bazin believes he has suppressed the resistance of the water to the forward movement of the vessel, and in so doing he has not only added to the speed, but has secured, he says, great economy in motive power as well. To attain this end he designed a vessel in which a flat rectangular deck would be supported by hollow disc wheels of steel running upon their axes. Experiments were made to show the action of these wheels in the water, and in the presence of a large company they were repeated a few days ago by M. Bazin in a tank constructed for this purpose at his Levallois Works. First, a hollow wheel was placed in the tank, and it floated vertically with about a third of its bulk immersed. Spun round without any forward movement, the wheel continued to revolve for some time without moving from its place, and this proved to M. Bazin that he could not rely upon the revolution of the wheel alone for the propulsion of the vessel. He then pushed the wheel forward without revolving it, and the effect was exactly the same as with an ordinary keel, that is to say, it threw up a good deal of water in front and left a trail behind. Moreover, it only advanced four or five feet, and did not show the slightest tendency to revolve. This convinced M. Bazin that he would have to give to the wheel both a revolving and a forward motion. Thereupon, spinning the wheel and pushing it forward, the hollow disc travelled the whole length of the tank with scarcely any agitation to the water whatever. Still pursuing the experiments, the inventor gave a more convincing illustration of the absence of any resistance and friction with the revolving disc. Two sticks were placed in the water, and a disc was propelled horizontally. On meeting the sticks the wheel pushed them forward a few inches and then stopped. Repeating this experiment with a revolving disc, the wheel passed over the sticks, which sank under the wheel and rose at the identical place, while the disc continued its course to the end of the tank. After thus proving that the wheel must have both a revolving and a forward movement, M. Bazin soon found that nothing was to be gained by revolving the disc too quickly, and that it was merely necessary to do this in proportion to the propelling force of the screw. If anything, too much power upon the wheels would be likely to cause a certain amount of friction. Under these circumstances, the relative power upon the propeller and the wheels would have to be calculated with a certain nicety, as the discs would have to turn in exact proportion to the distance covered by the boat. This fact having been settled, M. Bazin proceeded to demonstrate the stability and speed of the wheels. A framework carrying six disc wheels, three on each side, was placed in the tank. A cord was attached to it and drawn up over a pulley, and carried a weight of 200 grammes, which represented a certain propulsive force. The frame was pulled back to one end of the tank, and allowed to go forward by the action of the weight at the end of the cord. According to the watch, the time occupied in travelling the whole length of the tank was twenty-three seconds. The same experiment was then repeated with the wheels revolving by clockwork, and though losing two or three seconds at the start before getting up full speed, the apparatus went from one end of the tank to the other in eleven seconds. By comparing these results, M. Bazin estimates that the speed of a disc wheel steamboat would be 31 or 32 knots, while the smaller power required results, according to his estimate, in an economy of about 66 per cent. of coal. One of the advantages claimed for the system is the practical impossibility of sinking. Supposing that one or two, or even more, of the wheels were perforated in collision, the vessel would not do more than sink a few feet, a fact which was exemplified by the inventor removing the plugs from two of the wheels, and allowing the water to enter. As soon as the water had entered to a certain height in the wheel, it turned up with the orifice at the top, thus permitting of the damage being repaired with the greatest ease. Meanwhile, it would be possible for the vessel to proceed at reduced speed. Having thus, as he considers, demonstrated the speed, economy, stability, and safety of the Bazin wheels, the inventor showed a working model in a large basin constructed for that purpose. As the model is on a scale of one-twenty-fifth of a Transatlantic boat, which it is proposed to build with a length of 130 m., the deck or platform represents a height of six or seven metres above the sea, while the upper deck is about 13 m. above the water level. The deck itself is built up with girders, and being hollow, it has an enormous carrying capacity, either for merchandise or coal. There are eight discs or floats, four on each side, and owing to their convex form they offer little resistance to the wind, while the head wind has a clear passage underneath the deck. In appearance the model is very elegant, and certainly destroys any prejudice that might be entertained against the form of the vessel. The motive power was supplied by dynamos, one working the propeller and four others turning the floats. Upon the connection being made the propeller revolved with great rapidity, and the wheels turned slowly, and after a few seconds lost in getting under weigh, the model sailed the whole length of the basin at great speed. To show the conduct of the vessel in rough weather, the water was agitated to represent waves, on the same scale as the model, of five to seven metres in height, and though rolling slightly at her moorings the model behaved splendidly when in motion. The miniature waves rose nearly to the level of the deck, but the model rode as steadily as in the previous experiments. It is claimed that in the roughest weather the passengers would feel very little movement of the vessel. In the experimental boat now being constructed the steering is done with an ordinary rudder, but it is proposed to steer the Transatlantic vessels by means of a column of water forced out of the stern by a pump, so that instead of the progress of the vessel being impeded by the resistance of a rudder, it will be assisted by the water thus expelled at the stern. On the boat taking up its berth it may be driven by the steering gear alone, and this acts, it is alleged, so efficaciously that the vessel can be turned round its own length.

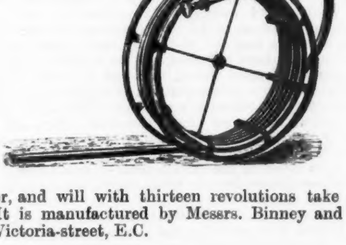


"It may be added that Admiral Coulombeaud, one of the foremost naval authorities in France, is taking a keen interest in the Bazin disc wheel boat, which he thinks is destined to effect great things in the water transport of the future. He admits having been sceptical as to the practicability of the system when it was first mooted, but after making a close study of the invention, he has fallen in with most of the ideas enunciated by M. Bazin. After going to some pains in making a comparison between the *navire rouleur* and the ordinary keel boat, the Admiral has come to the conclusion that the Bazin boat requires only about twenty-seventh of the power necessary to drive an ordinary boat of the same size at a given speed. Taking the Transatlantic Touraine as an example, he further states that if this vessel travelled at 20 knots, the disc wheel boat, with the same horse-power, would attain a speed of 47 knots; but as it is not proposed as yet to construct a vessel to run at more than 30 knots, such a boat would only require a fourth of the power employed in the Touraine. His deductions also show that the power necessary for the floats is one fourth of that employed for the propeller, and upon all the other points he is in accord with M. Parrot, professor of the Ecole Centrale, who has drawn up an exhaustive theory of the working of the Bazin boat. Admiral Coulombeaud does not believe that the present form of the disc wheel boat is a permanent one. It will be greatly modified to suit the different conditions of transport, and this is especially the case with the floats, though for Transatlantic vessels the present disc wheels could hardly be improved upon. The opinions thus expressed by some of the leading naval authorities in France give special importance to the trials that are to take place before long with the experimental vessel now being built, and if successful it is probable that a boat will be put in hand to run between Havre and New York. The following dimensions of the boat now building at the works of the Cail Co. may be interesting:—Number of floats, 6; diameter of the floats, 10 m.; length of the boat, 39 m.; breadth, 12 m.; superficial area of the midship frame, about 50 m.; burden, 274 tons; power developed by the boiler, 700-horse power, of which 550-horse power will be upon the propeller and 150-horse power on the axes of the floats. There will be a separate engine for the propeller and for each pair of disc wheels."

We have here history repeating itself. The boat on rollers is an invention as old as the steam engine.

GOSSAGE'S HOSE REEL.

WE illustrate a very simple and handy reel for garden hose. The engraving explains itself. The drum of No. 1 is 18in. in diameter, and will with thirteen revolutions take 60ft. of hose. It is manufactured by Messrs. Binney and Son, 62, Queen Victoria-street, E.C.



TRADE AND BUSINESS ANNOUNCEMENTS.—Mr. F. Heron, who for the last ten years has been general manager of the large works of the Phœnix Iron Company, Phœnixville, Pennsylvania, resigned his position, and has been appointed general manager and director of the Universal Construction Company, with works and offices in Chicago, Illinois. The Universal Construction Company has taken the North Chicago works belonging to the Illinois Steel Company, and is engaging in all classes of structural work.—Messrs. William Simons and Co., Limited, Renfrew, have received an order to construct a large and powerful hopper dredger for Devonport. The vessel is to be employed in removing blasted rock, and is the second vessel ordered for this purpose.

KING'S COLLEGE ENGINEERING SOCIETY.—At the general meeting on May 8th—Professor Adams in the chair—Mr. Mowat read his presidential address, his subject being "Horseless Carriages." The author commenced by briefly referring to their early history, describing and illustrating—by lantern slides—the various productions of Trevithick and other pioneers of steam road traction. He next cited several examples of coaches which had actually achieved considerable success on the road—those of Gurney, Hancock, Maceroni, Squire, and Hill—attributing their financial failure to oppressive tolls, the then existing railway mania, and also to public prejudice. Mr. Mowat then spoke of the rekindled interest in mechanical road carriages, resulting from their general use on the Continent and of the encouragement THE ENGINEER had given to motor carriage builders. Passing from this he briefly discussed the various advantages and disadvantages of different means resorted to for locomotion, the petroleum engine, electric and steam motors, showing that each had its good points. A few remarks on speed and gearing closed the paper. Mr. Mowat provided a large number of lantern slides of the various types of carriages. The meeting closed with a vote of thanks to Mr. Mowat for his most interesting and instructive paper.

THE CRINAN SHIP CANAL.

We have recently laid before our readers—ENGINEER, April 3rd, 1896—some information concerning the conditions of the Crinan Canal, which is attracting serious attention, and have given some particulars of proposals to form a new ship canal along the same route, capable of accommodating vessels drawing 18ft. of water. We now give some details of the proposed canal, but a short account of the present canal will in the first place be of interest.

The present Crinan Canal connects Loch Fyne with the Sound of Jura, and affords a sheltered passage from the Clyde to the West Highlands and islands, eighty-five miles shorter than the exposed voyage round the Mull of Kintyre, a promontory much obscured by fogs, and subjected at all times to strong currents, and the full force of the Atlantic Ocean. Leaving the sea in the Loch Gilp branch of Loch Fyne, the canal passes for about 2½ miles due north, for the most part along the shores of South Knapdale, thence in a north-westerly direction it runs through the Vale of Dail, where the summit level occurs, and finally, after traversing the shores of inner Loch Crinan, the canal enters the sea at Crinan, the total length being nine miles.

No less than eight locks occur between Loch Gilp and the summit level—which is 59ft. above high water of spring tides —and seven locks between the summit level and Loch Crinan —thirteen of them being 96ft. by 24ft., and the remaining two, at Crinan, being 108ft. by 27ft. The average depth of water in the canal is about 11ft., affording passage to vessels drawing 9ft. 6in. Nine reservoirs in the Knapdale Hills, ranging from 8ft. to 25ft. in depth and from 6 to 45 acres in extent, feed the canal, the surplus water passing into Loch Sween in the Sound of Jura. The canal is chiefly cut through chlorite schist, traversed by trap dykes, showing indications of considerable geognostic disturbance. The undertaking was authorised by Act of Parliament in 1793, and was carried out by John Rennie, father of the perhaps more famous engineer of the same name. The original capital was £120,000, in 2400 shares of £50 each, the first chairman being John, Duke of Argyll.

The canal was opened for traffic in 1801, and owing to bursts which occurred in 1805 and 1811, and great trouble both with reservoirs and embankments, received Government assistance for works and repairs. Without detailing the financial history of the enterprise, we may briefly state that by 1814, in addition to its share capital, the canal had incurred £67,810 of other obligations. In 1816 an Act of Parliament empowered the Barons of the Exchequer in Scotland to advance £19,400 to be expended under the supervision of the Caledonian Canal Commissioners, and this sum was spent by Thomas Telford in 1817 in repairing and renewing the lock gates, in providing new cast iron bridges, and in forming the breakwater at Ardrishaig harbour to enlarge and increase the shelter. Subsequently, by order of the Treasury, the pecuniary affairs of the canal were placed under the Barons of the Exchequer at Edinburgh, and by Act of Parliament in 1848 a new body of Caledonian Canal Commissioners was appointed, and the Caledonian and Crinan Canals vested in them as one undertaking. The Commissioners are the Speaker of the House of Commons—chairman —the Chancellor of the Exchequer, the First Lord of the Admiralty, the Vice-President of the Board of Trade, the Lord Advocate of Scotland, and the member for Argyllshire, with whom are associated the Duke of Argyll, Colonel Malcolm, of Poltalloch, and several other prominent noblemen and gentlemen connected with the district. The secretary is Lord Duncannon.

The traffic carried by the canal consists mainly of coals, bricks, barley, and general merchandise going north, and of slates from the Easdale and Ballachulish quarries, and granite from Mull and Bonawe quarries, with produce going south, whilst fishing boats use the canal freely, and the passenger and tourist traffic in the summer months is very large. The revenue is, however, decreasing on account of the small size of the locks and of the canal being insufficient in depth to carry the larger class of vessels now being employed in the West Highland traffic, which have, therefore, been forced to go round by the Mull of Kintyre. The canal, in short, is in exactly the same condition as when opened nearly 100 years ago. As far back as 1839, competent authorities pronounced the canal too small, and its enlargement was called for. The matter has, however, remained in abeyance, notwithstanding the enormous developments of the past half century.

The scheme now being actively canvassed consists in the formation of a ship canal with a uniform depth of 20ft. of water, capable of navigation by vessels of 1500 tons at all states of the tides; as contrasted with the present canal, to which access can only be gained at Ardrishaig for five or six hours of each tide. The summit level will be only 6ft. above high water of spring tides in Loch Fyne, and only one lock will consequently be required at each end. From lock to lock the length will be six miles, but including the dredged entrance channels, the total length will be nearly eight miles. The engineers of the scheme, Messrs. Crouch and Hogg, of Glasgow, departing from the route of the existing canal, have selected the lowest ground throughout, and with the exception of a stiff bit of rock cutting between Cairnbaan and Dunardry, the work presents no features of difficulty, the material being such that it could be readily excavated by dredgers cutting their own flotation. A storage reservoir will be formed at Crinan, whilst the reclamation of the foreshore —300 acres—at the head of Loch Gilp, with the excavated material, forms another feature of the undertaking. Estimates of traffic show a return of about 2½ per cent. on the calculated cost of £500,000. The benefit to the Highlands and islands will be incalculable, and the prosperity of this extensive district, and the improvement of the condition of its population by affording direct access to the commercial centres of Scotland, can hardly be over-estimated.

THERMAL EFFICIENCY OF STEAM ENGINES.—With a view to arriving at a definition of a standard or standards of thermal efficiency for steam engines, the Council of the Institution of Civil Engineers has remitted the question to the consideration of a committee, comprising the following members:—Dr. Alexander B. W. Kennedy, Member of Council, and Messrs. T. Hudson Beare, Bryan Donkin, James A. Ewing, J. Macfarlane Grey, Michael Longridge, W. H. Maw, and H. Riall Sankey.

THE INSTITUTION OF CIVIL ENGINEERS.

THE EQUIPMENT AND WORKING OF ROLLING MILLS.

AT the ordinary meeting on Tuesday, the 5th May, Sir Benjamin Baker, K.C.M.G., the President, in the chair, two communications dealing with English and American practice in regard to the equipment and working of rolling mills, were read.

The first paper on "American and English Methods of Manufacturing Steel Plates," was by Mr. Jeremiah Head, M. Inst. C.E. Mild steel was made by the Bessemer acid, the Bessemer basic, the open-hearth acid, the open hearth basic processes. Of these the two basic processes were suitable for phosphoric, and the two acid for non-phosphoric pig iron. Plates were made in England by the open-hearth acid, and in America by the Bessemer acid and by both the open-hearth processes. The Bessemer basic process had scarcely yet obtained a footing in America because of the abundance of pure ores from the shores of Lake Superior. About three-fourths of the pig iron made from these ores was sufficiently free from phosphorus for the acid processes. The capacity of American open-hearth furnaces varied between 15 tons and 35 tons, and they produced ten charges per week. In basic furnaces the slag was less abundant than in England, and was too poor in phosphorus to be a marketable by-product. Natural gas was still available in the Pittsburg district for heating, but was becoming scarce, and at its present price was as costly as producer gas, in spite of its much higher calorific value.

In England the intermediate process of cogging was now almost universal, whereas in the United States plates were usually rolled direct from ingots. The former plan permitted the use of larger ingots, and lessened the risk of wasters, as well as reducing the number of ingot moulds in use and slightly decreasing the waste in scrap. On the other hand, it entailed two re-heatings instead of one. An American melting-house, in which the ingots were poured from the top and subsequently cogged, was described. It was arranged on the ground level, with the exception of a small pit for the reception of the casting ladle. When full, this was lifted by an electric crane and poured into a series of ingot moulds, each standing on a bogie. These were then taken to the stripping-house, where an overhead hydraulic stripper held the ingot firmly down and at the same time stripped off the mould. In a typical English melting-house, the furnaces were on a charging platform, while the ingot moulds, standing in a casting pit, were filled from a travelling ladle. The moulds and ingots were lifted by steam cranes in front of the furnaces. A comparison of the number of lifts on the English and American systems showed an advantage in favour of the latter.

Ingot soaking furnaces were heated by coal, or by producer or natural gas, except in one case in Scotland, where no external heat was applied. Vertical furnaces with the lids level with the floor were in favour both in England and America. Where direct rolling was adopted, the ingot moulds were arranged in groups of six on a base-plate, and were filled from below by ducts radiating from a central runner. The upper ends of ingots so made were usually sounder than if they were cast from the top.

The typical American plate mill consisted of a single stand of three chilled rolls, driven by a single-cylinder non-reversing engine through a set of three pinions. The middle roll, which was smaller in diameter than the other two, was not driven. A copious supply of water kept the rolls constantly cool. The live roller tables in front and behind were pivoted, and were raised and lowered to admit the piece through the top or bottom openings. The English plate mill consisted of two stands of two rolls each, worked dry and driven by a pair of reversing engines. There were fixed live roller frames on one side and a traversing one on the other.

The American method of rolling an ingot tapered in two directions into a rectangular plate of equal thickness was next described. In England the cooling and flattening of the plate was effected on an iron-plated floor, and required a considerable amount of space and manual labour. During shearing the plate was manipulated by a gang of twelve men. A truck with universal motion had been introduced to assist in this operation, but had not been generally adopted. In America the plates as they left the rolls moved slowly along a series of live rollers 360ft. long, cooling on the way. At the far end, having been inspected and marked in transit, they were delivered to the shears. During the shearing operation the weight of the plate was supported by a number of inverted castors, which allowed it to be moved horizontally in any direction. The sheared plate was deposited in the railway wagons by an electric crane.

The ratio of saleable plates to ingots was much higher in steel than in wrought iron manufacture, because of the smaller furnace waste and the smaller allowance necessary for shearing. A table was given comparing results where ingots were cogged and where they were rolled direct. A plate mill, supplemented by a cogging mill, had nearly twice the capacity of one not so assisted. The yield and output were largely influenced by the shape and size of the plates manufactured.

The turning of the rolls to ensure uniformity of thickness of the plates was a somewhat delicate operation. The central portion of the roll was apt to become hotter than the ends, and the differential velocities thus caused tended to produce buckling of the plate. To compensate for this the rolls were often turned slightly hollow. A fresh difficulty arose in rolling very broad plates by the springing apart of the rolls. This could not be altogether avoided, and could only be minimised by making the rolls as stiff as possible and keeping them cool.

The American standard plate mill was not suitable for very narrow or thin plates. It was therefore sometimes supplemented by a universal mill for strips of breadths not exceeding 3ft. The English standard plate mill was smaller than the American, and was often supplemented by a larger mill for very broad plates, and also by a sheet mill.

Modern English plate shears were driven by a pair of reversing engines, which were capable of cutting 2in. plates without a fly-wheel, and were somewhat larger than American shears. The latter were driven by a single cylinder with a fly-wheel.

In the second paper on "Four American Rolling Mills," by Mr. Samuel T. Wellman, four mills, typical examples of modern American practice, were described in reference more particularly to the appliances which, during the last ten or eleven years had been brought to a high degree of perfection, to save labour and time in the passage of the material through the successive processes. In American Bessemer steel works where rails were made, the three-high blooming mill was almost exclusively used, having proved its superiority for producing large quantities of blooms of one size. The two-high reversing mill was, however, preferable when many sizes of blooms and slabs had to be manufactured, as all sizes of squares and flats within the range for which the mill was adapted could be dealt with on one set of rolls. The tendency was in the direction of the manufacture at every works of all sizes and shapes, so that it seemed likely that the reversing mill would largely take the place of the three-high blooming mill. The use of the three-high or Fritz mill was almost universal in the United States for finishing rails and other heavy bars.

At the Joliet works of the Illinois Steel Company the rail mill was fitted with automatic machinery, and the blooming mill was equipped with Siemens regenerative ingot heating furnaces and Wellman electro-hydraulic charging machines. The ingots were brought in front of the heating furnaces from the converting works on wagons, and all the operations for dealing with them at the furnaces were effected by these machines, the power for driving which was stored in a tank, charged first with air to a pressure of 100 lb. per square inch, and then with water until the pressure reached 400 lb. per square inch. The ingot, on leaving the furnace, was carried on a wagon driven by a wire rope to live roller tables, along which it travelled to a three-high Fritz mill with the three rollers fixed, the ingot, measuring 16in. by 6in., being rolled in thirteen passes to 7½in. by 5½in. The bloom was carried over driven rollers to the bloom shear, where the ends of the bloom were cut off and the remainder cut into two pieces, each of which was rolled into two rails. The scrap bloom ends dropped on a conveyor in the pit under the shear, by which they were lifted and dropped into wagons. The blooms now passed from the shears, first to the roughing rolls, at which they were manipulated by automatic machinery, then to the finishing rolls and on to the saws. The greatest output of the mill in twelve hours had been 679 tons of billets, and the best month's work 27,003 tons, the average output being about 500 tons per shift of twelve hours. The number of men employed was thirty-five per shift.

The rail mill at the South Works of the Illinois Steel Company, South Chicago, was equipped with a three-high blooming mill and finishing train, the ingots being heated in vertical gas furnaces of the Siemens type, arranged to use producer gas or crude petroleum. The ingots were drawn in and out of the furnaces by Wellman hydraulic cranes. The rail trains were 27in. in diameter, and were fitted with lifting and tilting roller tables for carrying the bloom through the successive passes. The capacity of the mill was very great, 1025 tons of rails having been rolled in twelve hours, and the monthly output having reached 38,093 tons.

The new rail mill at the Edgar Thompson Steel Works was next described. Its capacity had hitherto not been fully tested, but a monthly output of 36,300 tons of rails had been reached.

The new plate mill of the Illinois Steel Company was the largest and most complete in the United States. The train consisted of two stands of rolls of the Lauth three-high type, capable of dealing with ingots 24in. thick, and weighing seven or eight tons. The heating furnaces were of the Siemens type, and were charged by electro-hydraulic charging machines. Electric cranes were used for lifting and moving the plates at the cooling beds, for dealing with them at the shears, and for loading them into the railway wagons.

LAUNCHES AND TRIAL TRIPS.

THE trial trip of the last of the three steam hopper barges ordered by the Admiralty, and constructed by Messrs. Wm. Simons and Co., of Renfrew, took place recently at Skelmorlie with very satisfactory results. Six runs were made with and against the tide, and it was found that a speed of 9¼ knots was obtained, which was over the contract amount. The Admiralty were represented by Messrs. Hay, Stewart, and Scoggins, and the builders by Mr. Wm. Brown. The barge will in the beginning of next week leave for H.M. Dockyard, Devonport, where she is to be employed.

On Monday, April 27th, Messrs. Allsup and Co. launched from their shipbuilding yard at Preston, a steel twin screw tug, built to the order of the Preston Corporation. The dimensions are:—Length, 120ft.; breadth, 22ft. 6in.; depth, 11ft. The boat—whose yard number is 158—was named the Perseverance, and is a sister ship to the Enterprise, and both are principal tugs for work on the river Ribble. The hull was towed straight under the crane to receive the engines and boiler. The boiler weighs 27 tons, and is 14ft. 6in. diameter; the engines, two sets of compound surface condensing, with cylinders 17in. and 34in. by 24in. stroke, working at a pressure of 100 lb., built by Messrs. Allsup and Co. Messrs. Allsup have another tug of similar dimensions in frame, and a paddle excursion passenger steamer of 130ft. long well in progress, and a cargo steamer for the coasting trade ready for launching.

On Wednesday, May 13th, there was launched from the dockyard of Sir Raylton Dixon and Co., at Middlesbrough, the first of some steel towing vessels, built to the order of the American Petroleum Company, of Rotterdam, for the Scheepvaart En Steenkolen Maatschappy. These vessels are 170ft. in length, with a beam of 32ft. and depth of 13ft. 7in., having a deadweight cargo capacity of 1000 tons, and built under Lloyds' special survey, 100 A1. These vessels are intended for a new departure in the coal carrying trade across the North Sea. The screw collier, carrying herself 1700 tons of coal, will tow one of these craft with 1000 tons between the coal ports of the North of England and Rotterdam, and for this purpose they are specially constructed with water ballast, and fitted with sails and very heavy chains and anchors, so as to be quite independent and seaworthy, should the steamer have to cast them adrift at any time through stress of weather. The other vessels for the completion of this scheme are also being built by Sir Raylton Dixon and Co.

On Tuesday, May 12th, the s.s. Elizabeth Rickmers went for a very successful trial trip off the mouth of the Tyue. The steamer has been constructed by Messrs. Wigham, Richardson, and Co., to the order of Messrs. Rickmers, Reismuhlen, Rhederei, and Schiffbau, A.G., of Bremen, for their well-known Eastern service. She is built of steel on the web frame principle, 427ft. in length, 50½ft. beam, and 30ft. in depth, and will carry about 7200 tons deadweight on a moderate draught of water. She is also fitted with every accommodation for a limited number of passengers in the citadel amidships. The arrangements for working both ship and cargo are very extensive and of the most modern type, including eight steam winches as well as various other steam deck gear. The vessel is rigged as a two-masted schooner, and her lower masts are of such a length that she can go up the Manchester Ship Canal in ballast. The engines are of the quadruple-expansion type, self-balanced on the Yarrow, Schlick, and Tweedy system, and working at 215 lb. pressure. This type of engine is now coming to the front, not only on account of the saving in fuel due to the quadruple expansion, but also because of the absence of all vibrations due to the self-balancing. Messrs. Wigham, Richardson, and Co. have several more sets of self-balanced engines in course of construction for steamers of various descriptions. A large company of visitors were present at the trial trip, including Mr. Paul Rickmers, Mr. Heine, under whose superintendence the vessel has been built; Mr. J. Denham Christie, Mr. Patterson and Mr. Muir, of the builders' firm; Mr. A. Gulston, of Sir W. G. Armstrong and Co.; Mr. Duckitt, &c. During the trial the machinery worked in a most satisfactory manner, and immediately on the conclusion of the trip the vessel sailed for Middlesbrough under the command of Captain Andresen, to load.

On Tuesday last the ss. Leitrim, a fine spar-decked steamer built by C. S. Swan and Hunter, of Wallsend, for Mr. R. S. Hudson, of Sunderland, proceeded to sea on her trial trip. The vessel, which has been specially designed and constructed for the conveyance of frozen meat from the River Plate to the United Kingdom, is 365ft. between perpendiculars, by 48ft. 6in. beam by 30ft. 4in. depth moulded, and has been constructed to the highest class at Lloyd's for the carrying of a deadweight cargo of about 6500 tons. Two of the holds have been completely insulated for the conveyance of frozen mutton, and have an internal capacity of about 100,000 cubic feet, capable of carrying about 41,000 carcases. The refrigerating machinery, which is of the latest type, has been supplied by the Linde British Refrigeration Company on its system of ammonia and brine pipes; whilst for rapid handling of the frozen meat, as well as the deadweight cargoes, a large number of steam winches, with horizontal auxiliary boiler, which also supplied steam to the refrigerating plant, &c., and a complete system of quarter-breadth derrick posts and derricks, have been fitted in suitable positions, so that loading or discharging may be carried on at both sides of the vessel simultaneously. The derrick posts have been made of an unusual length, so that in the event of the vessel carrying cattle on the upper deck the derricks will work over all; and the upper and 'tween deck arrangements generally have been so planned to enable the vessel to carry a maximum number of live cattle, in the event of her being fitted for this branch of the meat trade, and, anticipating this, the 'tween decks are ventilated by Blackman's patent steam fans. The steering gear is of the new type of hydraulic gear supplied by Messrs. Fawcett and Preston. The machinery has been constructed by the Wallsend Slipway and Engineering Company, and has cylinders 24½in., 40in., and 68in. diameter by 48in. stroke, supplied by steam at 180 lb. pressure by two large boilers fitted with Serve tubes and Ellis and Eaves' system of induced draught. The whole of the machinery worked without a hitch, and to the entire satisfaction of all connected therewith, and during the progress of speed trials the mean speed attained was about 12½ knots. During the construction the vessel and machinery have been superintended by Mr. T. Graham on behalf of the owners, and he, together with Mr. R. M. Hudson, jun., was present on the trial trip. The builders were represented by Mr. G. B. Hunter and Mr. C. Stephenson; the engineers by Mr. L. Rusden; Messrs. John Brown and Co. by Mr. Gross and Mr. Brown; and the Linde British Refrigeration Company by Mr. Westwood. After the trial trip the Leitrim sailed for Barry Dock, where she arrived after a satisfactory run of sixty-four hours, and where she will load cargo for the River Plate.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

GOOD attendance on 'Change. The demand for steam coal continues good, with heavy shipments during the past week. Prices are steady. House coal shipments are very fair, for the season of the year. Tin-plates in moderate inquiry. The iron and steel trades continue fully employed.

Coal: Best steam, 8s. 3d. to 8s. 6d.; seconds, 7s. 9d. to 8s.; house coal, best, 10s.; dock screenings, 5s.; colliery small, 4s. 3d. to 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 46s. 1d.; hematite warrants, 47s. 5d. f.o.b. Cumberland; Middlesbrough No. 3, 37s. 3d. prompt; Middlesbrough hematite, 44s. 7d. Iron ore: Rubio, 12s.; Tafna, 11s. 3d. Steel: Rails, heavy sections, £4 12s. 6d.; light ditto, £5 f.o.b.; Bessemer steel tin-plate bars, £4; Siemens tin-plate bars, best, £4 2s. 6d.; all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel, coke, 9s. to 9s. 3d.; Siemens, coke finish, 9s. 3d. to 9s. 6d.; ternes, per double box, 28 by 20 C, 18s. 6d. to 20s. Pitwood, 15s. 3d. to 15s. 6d. Freights: Homewards are firm

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

MUCH gratification was expressed on 'Change in Birmingham on Thursday at the satisfactory nature of the Board of Trade returns for April in regard to those exports in which this district is especially interested. The increase in the value of metals for the month amounts to 27 per cent. as against April last year, compared with 22 per cent. for March, and 33 per cent. for February, this last advance being due to exceptionally large shipments of rails to India. This month again the increase is largely due to shipments of railway material. In fact, the demand for railroad material has been enormous. This month we exported £313,174 worth, as against £97,000 worth in April, 1895, an increase of 222 per cent. Next in the order of improvement comes old iron 206 per cent., bar and angle iron 86 per cent., hoops and sheets 55 per cent., galvanised sheets 25 per cent., and unwrought steel 21 per cent. The only noticeable decrease is in the export of tin-plates to the United States. This being the chief centre of the galvanised iron trade, much satisfaction is caused by the advance of 49 per cent. on the first four months of the year in that department, chiefly due to increased demand in Australia, South Africa, Argentina, and India. The exports of hardware and cutlery have increased 8 per cent. for the month, and 16 per cent. for the four months; machinery has advanced 4 per cent. for the month, and 15 per cent. for the four months; whilst engines have increased 22 per cent., and 28 per cent. for the two periods respectively. Railway rolling stock shows an increase of 109 per cent. for the month, and 92 for the four months. Cycles show a falling off for the month, but an increase upon the four months of 20 per cent. The statistics relating to Midland industries cannot but be considered very pleasing, though there seems no immediate prospect of an improvement in prices.

Steel continues in good call at £4 5s. for Bessemer billets and blooms, £4 12s. 6d. for Siemens. Angles and boiler plates, £5 12s. 6d. to £5 17s. 6d.; sheets, £7 5s. to £7 10s., and bars, £5 15s. Basic angles and girders are £5 10s., and boiler plates, £6 5s.

Some rather startling announcements concerning German competition in the galvanised sheet iron trade were made by Mr. W. W. Walker at the annual meeting of the Wolverhampon Chamber of Commerce on Wednesday. He stated that the price of black sheet iron in Germany was £1 per ton lower than it was here. The idea that German sheets were rubbish was an exploded fallacy. The Germans bought spelter from Silesia in Austria at 20s. per ton less than makers here could buy it. The Germans also got their chemicals cheaper. The wood for packing cases came from the Baltic, and was cheaper to the German, as were also the wire nails. The Germans were shipping the residuals from Antwerp and Hamburg to the Eastern countries at the same rate by the same steamer which came to London. Labour was between 30 and 40 per cent. lower than in England, and freights were lower in Germany. Reckoned altogether, he calculated there was a saving of £2 per ton in favour of the German manufacturer. He only knew of five corrugating machines leaving the country for the Continent, but their output would total up to something like 100,000 tons per year.

Pig iron prices are steadily maintained at recent rates—42s. for Lincolnshire forge, 41s. to 42s. for North Staffordshire and Derbyshire, and 40s. for Northamptonshire. Staffordshire cinder pig is 35s. 6d.; part mine, 40s. to 42s. 6d.; and all mine, 55s. Cold blast pig is £4 10s.

A meeting of manufacturers of Birmingham and Walsall in the trades likely to be affected by the introduction of the auto-car was held this week at the Walsall Chamber of Commerce. Mr. Crosbee—Messrs. Crosbee and Sons, Birmingham—presided, and there was a good attendance. Mr. J. Scott, of Walsall, proposed a resolution to the effect that the amendments suggested by the Walsall Chamber of Commerce, which have already appeared in our pages, *re* the Locomotives and Highways Bill, should be approved by the meeting, with the following alterations and additions, viz.:—(1) That the rate of speed in the towns shall not exceed five miles an hour, and ten miles an hour in the country. (2) That in case of a horse-drawn vehicle meeting an auto-car in a road too narrow for them to pass, the auto-car shall give way. (3) That whilst any tax remains on horse-drawn vehicles, such tax should equally apply to the auto-car. (4) That all auto-cars be numbered. This was seconded by Mr. D. Power—Walsall—and carried unanimously. Mr. Jaggar proposed the formation of an association, to be called "The Road Safety Association," for the purpose of arousing public opinion to the necessity of amendments to the Bill, with Mr. G. Harries as hon. treasurer, and Mr. A. Law—secretary of Walsall Chamber of Commerce—secretary. Those present were constituted a special committee to further the work of the association.

The greatest activity still reigns in the cycle trade and all things appertaining thereto. During the week an important conversion has taken place resulting in the formation of the Perfecta Seamless Steel Tube Company, with a capital of £145,000, divided into 30,000 cumulative 6 per cent. preference shares of £1 each, and 115,000 ordinary shares of £1 each, of which 10,000 preference shares and 30,000 ordinary shares have been applied for by the vendor, and will be allotted in full. The remaining 20,000 preference shares and 85,000 ordinary shares are now offered for subscription. The company has been formed to acquire the business of weldless tube and cycle fittings manufacturers carried on by Mr. Albert Edward Hill, at the Perfecta Works, Plume-street, Aston, established in 1891. Mr. Hill was one of the first manufacturers of seamless steel tubes, and owing to his great success in producing the finest quality, the demand has been so great that he has, during the last three years, increased the productive capacity of the works six fold. The site is freehold, and comprises 7200 square yards. It has a canal frontage of 800ft., and two private basins. The plant is modern and of the best character. The profits of the concern from April 1st, 1893, to April 30th, 1896, after making provision for depreciation, &c., is certified to be £20,597, and the net profit for the nine months ending April 30th, 1896, at £11,513, or at the rate of £15,351 per annum. The purchase price is £131,000. The vendor guarantees the book debts, and guarantees a profit of not less than £40,000 in the first two years, and will deposit securities to that amount with the company.

The Cycle Contract Company has just been registered with a capital of £20,000 in £1 shares, to carry on the business of manufacturers of and dealers in cycles, tubes, tires, parts, accessories, india-rubber, &c., mechanical engineers, fitters, machinists, founders, wire-drawers, tube-makers, metallurgists, saddlers, &c. The number of directors is not to be less than three nor more than ten. The subscribers are to appoint the first, the remainder as the company may decide.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—The position continues one of activity as regards the engineering and all the principal iron-using industries of the district, with a large weight of both raw and manufactured material going into consumption; but the deliveries are almost entirely on account of contracts placed some time back. The result is that although both furnaces and forges are mostly kept fully going with orders already on the books, they are just now booking little or no new business of any moment, and although the present lull as regards actual buying is regarded as only temporary, it has for the time being a depressing effect upon prices. Makers and manufacturers are, however, still confident as regards the future; and the only really serious result I hear of, following the falling-off in trade during the last month or so, is that the Wigan puddling forges of the Pearson and Knowles Company have been closed, owing, I understand, to the absence of foreign business to keep them going.

Business on the Manchester Iron Exchange all through continues extremely quiet, little or no new buying of any moment coming forward either in raw or manufactured material, and there is a good deal of pressure to sell for immediate delivery at very low figures, especially with iron held in second hands, whilst here and there makers are perhaps not quite so firm as they have been. As regards local brands of pig iron, makers are still holding to 46s. 6d. less 2½, for foundry qualities, but in forge numbers they would have to give way to secure orders. In district brands some very low-priced parcels of Lincolnshire forge are offering in the market at about 9d. under makers' quoted rates, which remain at 41s. net cash, with foundry still quoted 43s. delivered Manchester. Derbyshire has shown a slight giving way upon late rates, and for delivery here foundry brands scarcely now average above 46s. net cash. Outside brands are being cut very low in the open market, good foundry Middlesbrough for immediate delivery being obtainable at 45s. 9d. to 46s.; although makers quote 46s. 4d. to 46s. 10d. net cash, delivered Manchester. Eglinton is offered freely at 46s. 6d., and Glengarnock 47s. to 47s. 3d. net prompt cash, delivered Lancashire ports.

In the finished iron trade makers are in most cases kept well engaged on specifications in hand, but there is a continued falling off in the weight of new business coming forward, with the result that prices show a weakening tendency, although no really quotable change can be reported, except in the case of one large concern. For Lancashire bars £5 10s. remains about the minimum, with North Staffordshire qualities ranging from £5 10s. up to £5 15s. Very low prices are being taken for sheets, £6 17s. 6d. to £7 2s. 6d. and £7 5s., according to quality, being the average figures. Hoops are steady at the Association list rates of £6 2s. 6d. for random to £6 7s. 6d. for special cut lengths, delivered Manchester district, with 2s. 6d. less for shipment.

Only a moderate business is reported generally in the steel trade, with no appreciable alteration in prices. Hematite makers still hold to 58s., less 2½, as the minimum for good foundry qualities, but merchants are taking 1s. below this figure. Steel billets remain at about £4 7s. 6d. net cash; local steel bars, £6; and boiler plates, £6 5s. to £6 7s. 6d., delivered here.

In the metal market an active demand continues to be reported generally, and although there is no official alteration in list rates for manufactured goods, the tendency is in an upward direction.

The usual monthly returns of the principal engineering trades union organisations show a continued substantial improvement in trade and a further considerable decrease in the unemployed list. The Amalgamated Society of Engineers has now only about 2½ per cent. of the total membership on donation benefit, which is a less percentage than has been reported for six years past. In the Manchester district the position is even better, only 1¾ per cent. of the local membership being on out-of-work support, all the leading firms in the district being fully employed, whilst there is a continued increasing demand for pattern makers. The Steam Engine Makers' Society has not more than 1 per cent. on donation, and this would have been still further lessened but for the dispute on the North-East Coast, which has for the time being acted as a check to the steady decrease in the number of out-of-work members on the books of the society that has been going on during the last twelve months. The returns as to the state of trade continue much as indicated last month, increasing activity being reported generally, some of the leading branches, such as stationary engine building, being now full of orders for a considerable time forward.

The Amalgamated Society of Engineers is this year in a position to present a very satisfactory annual report, showing substantial progress, both numerically and financially. Only on two former occasions has the number of admissions during 1895 been exceeded, the membership at the end of the year being 79,134, or a clear gain of 3624 members, as compared with the previous year, whilst the society has now 554 branches. With regard to the financial position, the total assets of the society have risen from £184,601 to £206,115, this sum including the superannuation levy and funds invested. The income for the year was £296,959, or £28,588 more than in 1894, this being the greatest yearly income since the formation of the society. Turning to the expenditure, which reached a total of £278,696, or a decrease of £2828 on the previous year, donation benefit has been reduced from £138,976 to £108,947, owing to the substantial decrease of unemployed members, which would have been more marked, the report states, but for the social war towards the end of the year. Sick benefit cost £45,726, and superannuation £58,990; funeral benefit amounted to £12,375; contingent benefit, £8108, or an increase of £5620; benevolent grants, £3867; accident benefit, £2700; whilst management expenses amounted to £22,466, which was a little less than in 1894. The society commenced the year with a balance of £160,093, which was now increased to £169,577, a sum of £21,338 having been taken from the general balance for the superannuation reserve fund. As regards the employment returns, there has generally been a steady decrease in the out-of-work list all through the year, with the exception of the period of the Belfast and Clyde labour disputes, and then the increase was only comparatively slight during November and December, and the total percentage of unemployed considerably less than at the same period the previous year.

At a meeting of the Northern Society of Electrical Engineers, held on Monday in Manchester, Mr. John Hesketh read a paper on "The Use and Economics of Rectifiers for Arc Lighting." Of all the existing systems of arc lighting, he said, scarcely one existed in which some glaring inefficiency did not appear, and it was undoubted that there were more inefficiencies in our present arc lighting methods than in any other branch of electrical engineering. The blue tinge of the alternating arc was an objection which might be overcome by colouring during diffusion, or alteration in the constitution of the carbons. Amongst the possible solutions of the question of efficient arc lighting were the following:—Alternating current arcs, with a separate transformer for each lamp; arcs, three in series of 100 volt network, or separate transformer for three arcs; any number of arcs in series off an alternate current transformer giving varying voltage and constant current, and delivering alternate currents into the lamps; or, as in the latter case, but with a commutator or rectifier in the secondary circuit, so that pulsating currents were delivered into the lamps. The balance of advantage was greatly in favour of the third solution, as in addition to every economy gained by systems using only one type of generating plant, it possessed the great advantage of giving arc lamps a photometric curve very nearly equal to that of an ordinary continuous current arc. Mr. Hesketh then described in detail a type of rectifier for arc-lighting, which he said consisted of two parts—a constant current transformer, and a synchronous motor—in which was fixed the rectifier commutator. In arc lamps intended for use with rectified currents, main cores should be laminated, and the bobbins split, but this need not be done for the shunt coils. The pull on the core was rather less, and was more sluggish than with a continuous current, so that a fresh adjustment was necessary. The lamps were also perceptibly longer in striking than with continuous currents, but the illumination from a rectified arc lamp was not perceptibly different from that of a continuous current arc. There was also an undoubted influence on telephone circuits when rectified currents were used in series circuits, as generally arranged. The means for the prevention of such interference were peculiar to each case, but, speaking generally, they were such as applied to the prevention of interference of one telephone line with another—perfect electrical balance on the circuit and perfect insulation.

In the coal trade the amount of business doing in the better qualities shows a decided falling off, and except where pits are going on short time, stocks are accumulating. With the present exceptional weather, requirements for house fire purposes are necessarily being considerably curtailed, and very few of the local collieries are now running above four days per week, some of them not exceeding three.

Quoted list rates are without alteration, but there is a disposition to give way upon present business of any moment, and supplies from Yorkshire and Derbyshire are offering at extremely low figures, in some cases quite 1s. to 1s. 6d. under the quotations of Lancashire collieries for similar qualities. In the lower qualities of round coal, for steam and forge purposes, business continues slow, with supplies excessive, and prices as low as ever. At the pit mouth best Wigan Arley averages 9s. 6d. to 10s. Pemberton 4ft. and seconds Arley, 8s. to 8s. 6d.; common house coals, 6s. 6d. to 7s.; with steam and forge coals, for inland sales, averaging about 6s.; but quantities for anything like prompt clearance obtainable at 6d. to 9d. less. Engine fuel is less plentiful, so far as local supplies are concerned, with a hardening tendency in prices; but with slack coming in more freely from other districts, any really general upward move is checked. Common slack can still be bought readily at 3s. to 3s. 3d.; good medium sorts, 3s. 6d. to 4s.; and best qualities fetching 4s. 6d. up to 5s. in some cases, at the pit mouth.

A moderate business is doing for shipment, but only at very low figures; ordinary steam coal, delivered Mersey ports, or Partington tips, Ship Canal, averaging 6s. 9d. to 7s. 3d. per ton.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

CONSIDERING the season of the year, the pits are fairly well employed. Many of the smaller collieries engaged in the production of house and gas fuel are not doing much, although four to five days a week is the time worked by the larger pits. House coal is in poor demand. Although the lowest summer prices are at present in operation, this seems to have no stimulating effect in the trade. The Metropolis is taking but a poor supply, which is accounted for by the very keen competition of seaborne fuel. Values continue low, and concessions have to be made to effect sales of any consequence. A quiet trade in this class of coal is now looked forward to, and stocks are at present accumulated at one or two of the collieries.

Quotations are as follows:—Best Silkstone, 8s. 3d. to 9s. 3d. per ton; ordinary, 6s. 9d. per ton; Barnsley house, 7s. 3d. to 8s. 3d.; Flockton, 7s. to 7s. 6d.; secondary sorts from 6s. 6d.; while thin seam coal only realises 6s. per ton. There is a better business doing in steam fuel, and the season's trade bids fair to be a good one. A large increase is reported in the tonnage sent to Hull and the other Humber ports. For the month of April just ended the trade done by Yorkshire pits with Hull exceeded that of April, 1895, by 12½ per cent., or more than 10,000 tons. Grimsby has also taken an increased tonnage. The railway companies are taking a large amount of hard coal on contract account. Values remain very much the same as when last reported.

Barnsley hards, 6s. 6d. to 7s. per ton, while secondary qualities realise 6s. per ton. There is only a moderate business doing in gas coal, while manufacturing coal is in fairly good request. Small coal is rather scarce, owing to the heavy demand for the coke trade. This has had the effect of stiffening values, which range as follows:—Small nuts, 4s. 3d. to 5s. 3d. per ton; screened slack, 3s. 3d. per ton; pit slack, 2s. 6d. per ton; smudge, 1s. to 1s. 6d. per ton.

The satisfactory feeling which has existed in the heavy industries for the last few months still continues. There has been an excellent demand for Swedish Bessemer steel. This is due to the cycling "boom," at present in full swing. It is rumoured that one firm of cycle makers in Coventry alone have placed an order for 2000 tons of this material. Makers are now full up with work, and are not very eager to accept any more orders at present. Values range from £9 10s. to £15 15s. per ton f.o.b., and there is a general idea that these figures are not the top prices by a long way. Manufacturers in this city are continually expressing their regret that this cycle business was not secured for Sheffield at the outset.

In the lighter industries business is not so flourishing. A good trade is at present doing in hammers, spades, forks, shovels, and similar field and garden tools, and one or two local firms have of late fully doubled their output. Large quantities are being forwarded to South Africa, West Australia, and other mining districts. An increase in the home demand has taken place since the development of the allotment movement. The tool trade is in an excellent condition. The introduction of the Sloyd system and of technical education in schools has had the effect of creating a large demand for joiners', carving, and similar tools. Makers of anvils, vices, and heavy engineers' tools, report a very good trade. The local file industry is considerably disturbed at present by a wages dispute. Trade being good, the men are asking for the return of the 10 per cent. they conceded to their masters when they were badly off for work. The masters appointed a committee to consider the question, and they recommended the employers to comply with the request. The general body of the masters, however, have decided not to do so, and meetings of both sides are being held. It is hoped that an amicable arrangement will yet be come to, so that the activity in trade may not be interfered with.

Hardware and cutlery during April showed a considerable increase in the foreign markets, the value of exports having been £162,803, against £149,540 for April of 1895. Australasia and the British Colonies generally showed the largest increases. In unwrought steel last month's foreign business reached a value of £191,625, against £157,274 for April of 1895. All markets showed an increase except Holland and France.

The directors of the Parkgate Iron and Steel Works have been able to present a better report of the operations of the company for the year ending March 31st last than they did for the previous twelve months. Whilst the late depression in trade continued for nearly the whole of the first half of the past year, an improvement has since set in, resulting in an increased demand for the different materials produced at the works. The whole of the blast furnaces, five in number, have been in full operation since the middle of February last, whilst the steel works have also been fully employed. The falling off in the demand for finished iron still continues, but this is in some measure compensated for by the increased demand for steel. The gross profit made during the year was £15,507 17s. 4d.; after paying interest on debentures, and writing off £3000 for depreciation, the dividend is £3 per share, carrying forward £938 17s. 3d. The shares are £100—£75 paid up.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

BUSINESS has been much interfered with this week in this district by the strikes of engineers at Stockton, Middlesbrough, and the Hartlepools, and the threatened extension of the dispute to other parts of the North of England. Naturally buyers will not operate under such uncertain and unsatisfactory circumstances, and the demand in almost all departments is practically paralysed. The precipitate action of the Stockton engineers, who were the first to strike, is generally condemned even by their own class in other parts of the district. The matter in dispute is a comparatively trivial one, and might easily have been adjusted by arbitration, as the masters offered. Besides this, the matter does not affect the men at present, and will not until September, and before that period some settlement might have been amicably arrived at, without any dislocation of the trade of the district. The strike came as a surprise to almost everybody, and it is not easy to believe that so small a grievance could have such widespread results. At one of the leading engineering establishments, which employs over 2600 hands, who have all stopped, the total sum in dispute is only 3s. 6d. per week—seven men at 6d. per week each. That the conduct of the men is unreasonable does not admit of doubt, and many of the men themselves who have been obliged to come out are dissatisfied that they have had to stop on such a slight pretext, just when they were getting into regular work, and were earning fair wages.

The dispute has arisen in this wise. When at the end of March the employers and the engineers entered into an arrangement that the members of that society were to have 1s. per week advance at once and another 1s. in September, the masters believed there were in the society none but skilled men earning over 30s. per week. But it turns out that the constitution of the society has been altered, and there are now admitted to membership unskilled men earning at present under 30s. per week. These include machine men, planers, &c. Of course the employers never intended that these lower paid men should receive the same advance as the skilled men, because in their ageements with all the other classes of workmen it is stipulated that all men receiving under 30s. per week will have an additional 6d. given them in September, and not 1s. as in the case of the higher paid men. They did not see their way to pay the lower class members of the Engineers' Society on different terms or similarly paid men in other departments would agitate to have like treatment. Besides, when reductions were being made during the period of depression, all the men with the lower wages had their wages reduced by smaller amounts than the skilled men, 6d. being taken off from the former where 1s. was demanded from the latter. Naturally the masters thought it right that advances should be made in like proportions.

But the officials of the Engineers' Society are determined to hold the masters to their agreement, even though it was made under a misapprehension, and so far they have not accepted the offer of the masters to refer the dispute to arbitration, though the Tyne and Wear men appear to favour that step, as do a good many who are out on Tees-side. The Stockton men were the first to come out, and the Middlesbrough men followed to support them. The employers then agreed to give 25 per cent. of the members of the Engineers' Society their notices, but the Hartlepool men all struck when this action was taken. It is regrettable to see trade complicated by a dispute which, in the first instance, was of such slight dimensions and of such trivial importance, and which might so readily have been settled by arbitration, without any stoppage of work.

The boilersmiths and platers at the Tees-side Iron and Engine Works, Middlesbrough, have come out on strike for an advance of wages, and the same classes of men have given notice to cease work on Saturday at Messrs. Head, Wrightson, and Co.'s works at Thornaby.

The price of Cleveland pig iron has been reduced 6d. per ton this week, and there can be little doubt that the fall has been induced by the engineers' strikes, which have made the future of the market so uncertain. Consumers generally have withdrawn their offers, or have reduced them to figures at which sellers will not at present look. No one apparently needs to buy iron for prompt delivery, as consumers have fair stocks or have arranged with makers for supplies. This is not a time to buy for forward delivery; in fact, for the present, speculation is altogether suspended. No. 3 Cleveland pig iron has dropped to 37s. 3d. per ton for prompt f.o.b. delivery, a lower rate than has been known since January, but it is stated that makers have not taken so low a figure. It is 1s. 9d. per ton below the best price of the year, and only 1s. above the worst. Few buyers will pay more than 37s. Cleveland warrants were as low as 37s. 1½d. cash on Monday, but on Tuesday advanced to 37s. 6d., though on Wednesday they fell back to 37s. 3½d. The general market has not responded to the changes in warrants, being depressed by the labour troubles. No. 1 Cleveland G.M.B. pig iron is 38s. 6d. to 38s. 9d; No. 4 foundry, 36s. 9d.; grey forge, 36s. 3d.; mottled and white, 36s., the last-named being relatively dearer than the better qualities, as both mottled and white are so scarce. Shipments are well maintained, in fact they are much better than might have been expected, considering the heavy exports of March and April. The total exports of pig iron this month up to Wednesday from the Cleveland district were 45,888 tons, as compared with 46,957 tons in April, and 46,521 tons in May, 1895, to 13th. Local and inland deliveries are also good, yet the stock of Cleveland pig in the public warrant stores increases, Connal's having on Wednesday night last 197,041 tons, or 3285 tons increase this month. Cleveland hematite pig iron is in poor demand, and weak in price, some sales of M. Nos. having been made at 45s. 9d. per ton f.o.b., though 46s. is the regular quotation. Deliveries are very good to Sheffield, though they are hardly satisfactory on export account.

A stronger business is being done in steel rails, and manufacturers have no difficulty in securing plenty of orders; indeed, they can hardly keep up with their contracts, though they are working more fully than for years. Heavy steel rails are quoted £4 10s. to £4 12s. 6d. net at works. Steel billets are about £4 5s. net at works, but are scarcely in such good demand as rails. The plate and angle manufacturers have not yet found their trade detrimentally influenced by the engineers' strikes, but they expect the demand to fall off if the dispute is not soon settled. The quotation for steel ship plates is £5 2s. 6d.; steel ship angles, £4 17s. 6d.; iron ship plates, £5; iron ship angles, £4 15s.; all less 2½ per cent. and f.o.t. Common bars are firm at £5, less 2½ per cent. f.o.t., and works are well employed.

The current going works and business of Black, Hawthorn, and Co., engineers, Gateshead, were offered for sale by public auction on Tuesday at Newcastle. The works are freehold, and occupy an area of about six acres. They adjoin and have direct access to the North-Eastern Railway. The firm have been well known as manufacturers of tank locomotives and colliery engineering work. The minimum price at which the place would be sold was announced by the auctioneer to be £40,000. There was no bid, and the property was withdrawn.

The coal trade is quieter, even in the steam coal branch, now that the rush of shipments brought about by the opening of the navigation season is over, and as some of the steam coal pits are not fully employed, there is some easing in the price of best steam, though 8s. 3d. f.o.b. is still quoted.

The death is announced of Mr. John Nixon, one of the founders of the Northumberland Miners' Association, for many years its treasurer, and of late years its president. He was seventy-five years of age.

The sale of collieries referred to last week is that of the Earl of Durham's. Altogether he sells fourteen collieries, producing 12,000 tons per week, and employing 8000 men, to a syndicate headed by Sir James Joicy, who are already the owners of thirteen collieries, employing 4000 hands.

Blast furnace coke is cheaper, the supply being larger, and exports are easier, so that more is offered to local blast furnace owners, who have this week been able to buy at 13s. 6d. per ton, delivered on Tees-side. At the Malton Colliery, near Lanchester, Mr. S. A. Sadler, of Middlesbrough, the owner, is adding thirty-five coke ovens to the seventy already in operation.

So far as the voting of the Durham miners has been made known, they seem as antagonistically disposed as ever to a continuance of the Concilliation Board, the commendations of their executive with respect to the benefits of the organisation having apparently had little effect upon them.

Coal shipments last month from North-Eastern ports reached 1,447,149 tons, or 67,295 tons more than in April, 1895.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE was a smart drop in the prices of warrants towards the end of last week, in consequence of the fresh dispute in the marine engineering trade. It is alleged that "bears" who had for some time being doing little or nothing, eagerly took advantage of the anticipated spread of the labour quarrel to the Clyde and Belfast to depress prices, and the expectation was therefore formed that the market would likely in a few days exhibit a smart reaction. The favourable nature of the Board of Trade returns was not without its effect in steadying the market, and there is besides a pretty wide-spread conviction among those connected with the shipbuilding and marine engineering trades that an amicable settlement of the quarrel between employers and workmen is likely soon to be effected. Scotch warrants fell from the best point of last week 9d.; Cleveland iron, 6d.; and Cumberland hematite, 8½d. per ton. The price of Scotch in a few days improved to the point from which the fall began, and hematite gained 4d., and Cleveland warrants 3d. of the decline. A good deal more warrants changed hands this week than for several weeks past, the transactions being largely speculative. Business was done in Scotch warrants from 45s. 10½d. to 46s. 4½d. cash, and 46s. 1d. one month, but fluctuations continue to take place.

There are eighty-one furnaces in blast in Scotland, compared with seventy-six at this time last year; and of the total, forty-one are producing ordinary, thirty-seven hematite, and three basic iron.

A small decrease has occurred in the stock of pig iron in Connal and Co.'s Glasgow stores, which now contain about 356,000 tons, compared with 282,700 tons at this time last year.

While pig iron warrants have been fluctuating, owing to reasons above explained, the prices of the special brands of makers' pig iron have been comparatively steady. The quotations are as follows:—Govan and Monkland, f.o.b. at Glasgow, Nos. 1, 47s.; Nos. 3, 45s. 9d.; Carnbroe, No. 1, 47s. 3d.; No. 3, 46s.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie, No. 1, 50s. 6d.; No. 3, 48s.; Calder and Summerlee, Nos. 1, 51s.; Nos. 3, 48s.; Coltness, No. 1, 53s. 6d.; No. 3, 49s.; Glengarnock, at Ardrossan, No. 1, 51s.; No. 3, 47s.; Eglinton, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Dalmellington, at Ayr, No. 1, 47s.; No. 3, 45s.; Shotts, at Leith, No. 1, 53s.; No. 3, 49s.; Carron, at Grangemouth, No. 1, 52s.; No. 3, 48s.

The pig iron shipments are considerably larger than last week, when, however, they were exceptionally small. In the past week the total has been 8003 tons, which compares with 7317 in the corresponding week of last year. There was despatched to Australia 400 tons; Holland, 600; India, 300; United States, 65; Canada, 100; South America, 20; France, 215; Italy, 140; Germany, 235; Belgium, 40; Spain and Portugal, 68; China and Japan, 150; other countries, 210; the coastwise shipments being 5450, against 6382 in the same week of last year.

The malleable iron department is fairly active, the home trade absorbing a considerable amount of iron. The demand for abroad is not what it might be, but considerable shipments are being made to places where foreign competition has little effect, or where Scotch finished iron is preferred on account of its distinctive qualities. The steel industry is very busy, probably busier than ever before in the course of the history of the mild steel manufacture. Scarcely anything is heard about prices, which are understood to be nominally without alteration.

The coal market continues very dull and heavy. A fair volume of business is being done; in some qualities, indeed, the turnover might be said to be extensive. Supplies are, however, so very large that prices are kept down, and the figures are nominally without change. The total coal shipments in the past week from Scottish ports amounted to 180,743 tons, against 161,366 in the corresponding week of last year.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE result of personal observation over a considerable extent of the Brecon, Midland, Cambrian, and London and North-Western lines, during the last few days, has been to prove that South Wales coal is maintaining its position against that of North Wales. Monmouthshire coal, that of Nantyglo, Tredegar, Ebbw Vale, is well in evidence, and even patent fuel, I see, is becoming of more general use. As for anthracite, I find that the use is extending. and amongst some good customers the Crystal Palace is named as one.

The steam coal trade at Cardiff last week was, as usual, in thorough animation, but house coal was very slack, the exceptionally fine weather telling adversely. Prices falling. Monmouthshire coal for shipment at Cardiff active.

Swansea Exchange report for last week indicates a more hopeful state of things, and there is now a strong probability, as was remarked, that things are settling down into a more satisfactory condition, port statistics showing an increase of 10,000 tons over those of the corresponding week for last year. In coal there has been a good deal of activity, and three large steamers were cleared with anthracite for San Francisco, totalling 9993 tons.

Cardiff prices, mid-week, were as follows:—Best steam, 10s. 3d. to 10s. 6d.; best seconds, 9s. 9d. to 10s.; seconds, ordinary, 9s. 3d. to 9s. 6d.; drys, 8s. 7½d. to 9s.; best small, 4s. 9d. to 5s.; good small, 4s. 3d. to 4s. 6d.; seconds, 4s., drys, 3s. 6d. to 3s. 9d. House coal, best, from 9s. 9d.; No. 3 Rhondda, 9s. 6d.; No. 2 Rhondda, which is in fair demand for bunkering purposes, 7s. 3d. to 7s. 9d. German demands for anthracite are improving.

April statistics are just to hand, and show favourably in regard to coal and patent fuel, but a falling off in iron and steel shipments, as compared in each case with the returns for March.

Cardiff shipped in April 1,159,641 tons of coal, indicating a better trade even than January. Newport total was 241,636 tons foreign, and 83,719 tons coastwise. Swansea, 96,662 tons foreign, and 49,204 tons coastwise. Llanelly, 14,895 tons foreign, and 8107 tons coastwise. I note that for April the collective totals from the Welsh ports show that 14,145 tons of iron and steel have been shipped, 7928 tons of coke, and a quantity of patent fuel. The coast shipment from Cardiff since the beginning of the year has totalled 4,584,641 tons. Since January Cardiff has sent 21,534 tons steel, Newport, Mon., 11,658 tons; Swansea, 2998 tons. This exceeds late averages.

Last week I announced the success of the Barry Railway in getting access into Monmouthshire. This week, I am very gratified in being enabled to record the dispensation, at the hands of an unquestionably able and impartial committee, of the powers sought by the Bute Docks for the amalgamation with the Rhymney Railway. This gives it the powers and circumstances of a railway of its own, and places it not upon an unfair advantage over competitive powers, but upon the same level. As I remarked lately, the Taff has its railway and docks, the Barry theirs, and now the Bute has succeeded. This concession will restore the balance of power to an equitable position, and when the immense capital invested is considered, and the long period of up-hill and adverse time regarded, the concession is simply a reasonable one. In announcing the decision, the chairman said the Committee are of opinion that the Bill shall proceed, but that clauses be introduced giving equal facilities on equal terms in respect of traffic conveyed by any of the railway companies having access to the docks, similar to those contained in the Bute Docks Transfer Act, 1886.

The Port Talbot Railway and Docks Bill is the next one of importance to come on.

I see that in connection with Swansea a very important project has been revived, that of the floating of Swansea Docks. This is the scheme of Mr. Rosser, and has the advantage over others of a connection between all the docks at all states of the tide, and the formation of basins outside the present harbour. Dock gates are by this scheme to be constructed between the present piers; the water from the Tawe is to be brought through all the docks, and overflows are to be provided at various points.

The question now discussed in the district is whether the Harbour Trust will seriously consider this, or the other scheme, that of Mr. Westlake. Fairly, it may be stated that the Trust are thoroughly alive to every suggestion for improving the harbour.

With regard to the Llanelly Dock Bill, which will come before the House of Commons, an important communication has been received by the Harbour Commissioners from the Great Western Railway, proposing, it is understood—though particulars are not made public—an alternative scheme, which is to be duly and promptly considered.

Work has been resumed at the Trumble Colliery, Llanelly. The points in dispute have been referred to a committee of four. An agitation amongst the Ebbw Vale hauliers is causing some attention.

Swansea Exchange report in connection with the iron and steel trades, mid-week, indicates weakness in the pig iron branch; prices slightly lower. Most of the works in the finished iron and steel trades are well employed. There is no change in quotations for steel rails, bars, or sheets. Glasgow pig is quoted at 46s. 2½d., cash buyers. Bessemer and similar bars remain at past figures, and I am glad to note that a larger make is going on, though in tin-plate the quantity brought from works last week was in excess of shipments, so stocks have been again increased. For rails there is a fair demand. One cargo was sent away this week to Douglas. Cyfarthfa preparations for rail make are now understood to be complete. I note that the demand for bars is much improved, also for "small goods." A little better tone prevails in some of the tin-plate districts.

During last week sixteen mills were in operation in the Briton Ferry district.

I am pleased to record that a satisfactory dividend was announced last week at the half-yearly meeting of the Briton Ferry Steel Works. Mr. Bevan, the retiring director, was re-elected. I hear that a large foundry and extensive engineering works are projected.

Tin-plates are slightly better. The latest figures are: Swansea Siemens coke finish, 9s. 3d. to 9s. 6d.; Bessemer coke, 9s. to 9s. 3d.; ternes remain from 16s.; best charcoal, 12s. 6d. to 12s. 9d.

Patent fuel and coke prices, mid-week Cardiff, were unaltered. Pitwood a little firmer.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

FAIR accounts can be given of last week's business on the iron markets over here. A considerable degree of activity is noticeable in nearly all departments; raw as well as manufactured iron meets with a good demand, not only on home, but also on foreign account, and though prices have remained stationary for the last two weeks, there is so much firmness to be perceived in all branches of the iron trade that the bright confident tone of previous weeks was not only well maintained, but has even further increased.

With regard to the iron business in Silesia most satisfactory reports continue to be received. The blast furnace works are very busy just now, a considerable amount of large orders coming in. The malleable iron industry is also in a fair condition, the contracts booked reaching, in a number of instances, far into the last quarter. Some of the leading firms are contemplating the extension of their establishments, and there has also been talk of an additional rolling mill being built by a well-known Breslau firm.

On the Austro-Hungarian iron market the condition remains much as was previously reported. The position of producers is, on the whole, satisfactory, though competition is keen, which prevents prices from rising more quickly; but for most articles a very good inquiry is experienced, and compared to the same period last year, a decided improvement can be noticed for bars, girders and plates. With regard to the business in railway material, the hopes that were entertained at the beginning of the year have not been fulfilled; however, there is a fair activity going on at the shops generally. For hardware, a slightly better inquiry has been experienced, especially in Bohemia and Hungary. Prices show a rising tendency all round, but an official advance has not taken place lately.

No material change is noticeable on the French iron market, business in nearly all departments being satisfactory. Pig iron is becoming exceedingly scarce, and prices have, consequently, been showing a hardening tendency. In the manufactured iron and steel trade a strong tone is reported generally, quotations moving steadily in an upward direction. Exports during the past week have been rather heavier than formerly.

According to the "Comité des Forges de France," the French iron ore mines yielded 3,117,000 t. ore in 1894, output of the air-shafts being 665,000 t. Compared to the year before, the production of the iron ore mines increased by 232,000 t., while output of the air shafts was 23,000 t. higher than in 1893, total increase thus amounting to 255,000 t., or 7 per cent. against the previous year. Average prices were 3·07f. and 3·30f. p.t. The total quantity of iron ore, at the average price of 3·26f. p.t., was worth 12,297,000f., the number of mines being 71, while there were 45 air shafts.

In Belgium the business in iron and steel has been exceptionally strong during the week now past; large lots are being exported, and there are indications that a lively continuance of trade will be experienced for many months ahead. Prices for pig iron continue to show much firmness, although imports from Germany, France, and Luxemburg have been rather heavy. All sorts of structural iron are in in active request, and quotations are considered fairly satisfactory, although it is exceptional where any really appreciable advance is being got. Belgian export figures for the first two months of the present year show a fair increase against 1895; in manufactured steel export increased 180,000 t.; in steel rails alone 10,000 t., in girders 4000 t., more were exported than last year. Export in manufactured iron was 26,000 t. higher than during the corresponding period in 1895.

Demand and sale continue unusually brisk on the Rhenish-Westphalian iron market. Producers and buyers are entertaining the most hopeful views with regard to the development of the iron trade. There is, all things considered, good reason to expect a further improvement in occupation and in prices, and even if a temporary lull should set in, the orders on hand and those now offering would secure a brisk employment for at least several months to come. Iron ore is in active request, and fair prices are obtained. The Nassau ore mines have even ventured a slight advance, M. 9·70 p.t. being the list quotation for the 50 p.c. red iron ore. Siegerland qualities range between M. 2·50, 2·80, and 3·20 p.t. as before; two-thirds of the present output of the Siegerland ore mines have already been disposed of, a number of the orders booked reaching into the first quarter of next year. A good number of inquiries continue to be received in the pig iron trade, consumers being extremely anxious to place their orders for the last quarter, and stocks are very small in consequence. Figures for March show output in iron and steel to have been 551,000 t., which shows an increase of 70,000 t. against the same month last year. At present the blast furnace works are hardly able to produce the quantities required, especially basic is very briskly called for. List rates during the last week were:—Spiegeleisen, 10 to 12 p.c. grade, M. 59 p.t.; forge pig, No. 1, M. 53 to 55 p.t.; No. 3, M. 42 p.t.; hematite, M. 65 p.t.; foundry pig, No. 1, M. 65 p.t.; No. 3, M. 57 p.t.; basic, M. 56 p.t.; German Bessemer, M. 60 p.t. at works; Luxemburg forge pig, 56f. p.t., free Luxemburg.

The manufactured iron and steel industries are in exactly the same position as before, which means a good deal of activity at the mills and foundries and a strong upward movement in quotations.

There have also been rather more foreign orders booked upon the week, which has had the usual favourable effect on the tendency of the iron market. For bars and girders, and also for sheets, a vigorous demand is coming forward, and the heavier sorts of plates also meet with a lively request. Wire and wire nails have been in fairly good call, comparatively speaking; there are more export orders booked, and quotations begin to be a trifle more paying. The slight changes that have, since last week, taken place in the employment of the foundries and machine factories, have all been more or less in the direction of an improvement, and there is now hardly any branch of the iron trade that could be regarded as weakly or unremuneratively occupied.

Latest list prices per ton at works are as under:—

Good merchant bars, M. 118; angles, M. 128; girders, double T, free Burbach, M. 94 to 97; hoops, M. 120 to 125; billets in basic and Bessemer, M. 85 to 86; heavy plates for boiler-making purposes, M. 160 to 165; tank ditto, M. 135; steel plates, No. 1, M. 145; No. 2, M. 130; tank ditto, M. 120 to 125; sheets, M. 155 to 160; iron wire rods, common quality, M. 125; drawn wire in iron and steel, M. 118 to 130; rivet iron, M. 138; rivets, good merchant quality, M. 175 to 180; complete sets of wheels and axles, M. 280 to 290; axles, M. 220; steel tires, M. 200; steel rails, M. 118; steel sleepers, M. 110; fish-plates, M. 120 to 130; light section rails, M. 100.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, May 7th.

THE disturbing political conditions, are rightfully or wrongfull, credited with some of the hesitancy displayed by promoters and managers of many new industrial enterprises in the prosecution of work. Production of iron and steel has gone beyond daily and weekly demand. Prices have been shaded during the past few days on almost all products, despite the vigorous efforts made in several branches to preserve remunerative quotations. In the Western States, where agricultural interests have been presenting summer and autumn requirements, there is a better condition. The many small industries there depending on agriculture, mining, lake transportation, &c., are all buying freely, and the aggregate is quite an encouraging sum. In the regions east of the mountains trade and industry move at a laggard's pace. Pig iron at all points is perceptibly lower. The efforts made to preserve coke and lake ores 25 per cent. above a fair market price has checked demand. There is no escape from these quotations except in non-production, and that is a resort not to be thought of while a margin remains. Railroad building is not increasing, and a minimum of railroad work is being done. In many quarters the impression prevails that the formulation of a gold platform at St. Louis will stimulate and encourage investments of home and foreign capital on an extensive scale, sufficient to swing the pendulum in the other direction. The present dulness may terminate suddenly, but with the enormous production stronger prices are impossible unless exceptional causes should be precipitated. Coal production is in excess of all former years, and combinations of producers are securing more favourable margins to owners. General trade is not satisfactory, but an early improvement is anticipated. Gold exports keep the public in remembrance of the fact that their metallic basis needs watching.

AN ENORMOUS PLATE.—At the Cardiff Exhibition is a boiler plate some 70ft. long. We have received from the Stockton Malleable Iron Company, Stockton-on-Tees, particulars of a still larger plate, the largest plate ever rolled. The total length sheared is 76ft. 3in. Its rolled width varied from 5ft. 2in. to 6ft. 2in. The sheared width is 5ft., and the thickness 0·6in. The sheared weight of the plate is 5 tons 10 cwt. It was rolled on Tuesday, the 5th instant.

NEW PIER AND LANDING STAGE FOR THE CITY OF BANGOR.—A new pier and landing stage for accommodating the ferry and steamer traffic in the Menai Straits, at Bangor, was opened by Lord Penrhyn, yesterday, the day being observed as a general holiday. The pier is 1550ft. long, and 24ft. wide, and is constructed of iron screw piles, and steel girders which carry the timber deck. There are eight embayments upon which are built ornamental kiosks, and the head is increased in width to allow ample room for promenading. The landing stage at the end of the pier consists of floating pontoons approached from the pier by a bow-string girder bridge. The pier will be of great service to the neighbourhood, and will command a fine view of the Straits and Welsh mountains. The works, which have cost about £20,000, were designed by Mr. John J. Webster, M. Inst. C.E., Westminster, Mr. Alfred Thorne being the contractor.

THE INSTITUTION OF CIVIL ENGINEERS.—YORKSHIRE ASSOCIATION OF STUDENTS.—At the invitation of Mr. A. Creer, A.M.I.C.E., this Association made their first monthly excursion of this session to the York City Sewage Works. Meeting at the Guildhall on Saturday, May 9th, the visitors, numbering about thirty, were taken down the river in launches to Fulford, where the primary screening apparatus was examined, and also pumping engines, in duplicate, capable of dealing with 3,000,000 gallons per twenty-four hours. Taking boat again, the party was transported to Naburn, where the deodorising and precipitating processes were at work. A special feature, which caused much interest, was that of caking the sludge by compressed air at 80 lb. per square inch. Mr. Creer here, as at the former stage, gave a very careful description of the works, which have been carried out on the most modern and approved system. On arriving back at York a vote of thanks to Mr. Creer was proposed by Mr. S. Utley, seconded by Mr. C. R. Fenwick, and unanimously carried, this ending a most enjoyable and interesting afternoon.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

_ When inventions have been "comunicated" the name and address of the communicating party are printed in italics.

30th April, 1896.

9166. Buffing Pads for Boots and Shoes, G. Riley, Leicester.
9167. Lubricators, H. McClenahan, Liverpool.
9168. Cycles, D. Doyle, Youghal, Co. Cork.
9169. Instrument for Drafting Bodices, M. A. Fitton, Huddersfield.
9170. Elevators, R. Birtwistle, Manchester.
9171. Underground Conduits for Electric Railroads, W. Fairweather.—(*Munson, Roberts, Alston, Reid, and Reid*, ——.)
9172. Carding Engines, W. Hopkinson and R. Tyack, Accrington.
9173. Making Wire Cloth, J. Brodie, R. Miller, and R. Weir, Glasgow.
9174. Pressing Cloth on to Tenter Hooks, W. Thompson and A. W. Glover, Leeds.
9175. Golf Clubs, H. J. Just, Accrington.
9176. Apparatus for Catching Flies, R. Swann, Preston.
9177. Appliance to Assist Hearing, K. Macqueen, Bristol.
9178. Cycle Tires, S. Bunting and W. A. Courtland, Birmingham.
9179. Card Covered Raising Machines, J. and W. Blamires, Huddersfield.
9180. Cooking Ranges, A. T. Hebron, Whitley, Northumberland.
9181. Milking Apparatus, W. H. Lawrence and R. Kennedy, Glasgow.
9182. Gas Heating Apparatus, T. Fletcher, W. Russell, and Fletcher, Russell, and Co., Manchester.
9183. Pneumatic Ball Cushion Tire, A. L. Binns and J. F. Garvey, Liverpool.
9184. Water Decomposing Process, J. T. E. F. Cosson, Brussels.
9185. Making Pipe Joints, J. Wood and W. Clark, London.
9186. Folding Bedsteads, J. G. Winship, London.
9187. Sewing Machine, J. Marshall and E. A. Leech, London.
9188. Ink Wells, J. S. Mallary, J. A. Leonard, and C. P. Wilson, London.
9189. Bean Harvesters, A. A. Snure, London.
9190. Apparatus for Planing Blocks, J. S. Hoerner, London.
9191 Tire Shrinking Apparatus, M. D. Gould, sen., London.
9192. Churns, W. Deacon, London.
9193. Dust-bin, G. L. Lavington and E. A. Wright, London.
9194. Turbine, J. Farrar, Halifax.
9195. Fastenings for Door Knobs, J. Newbould, Sheffield.
9196. Knife-cleaning Machines, T. E. Peckett, Sheffield.
9197. Cycles, J. E. Hatch, Birmingham.
9198. Bicycles, J. E. Evered and D. G. Pappa, London.
9199. Internal Combustion Motor Engines, G. McGhee, Glasgow.
9200. The Cyclists' Tea Basket, M. O'C. Eccles, London.
9201. Veterinary Rasps and Files, J. E. Arnold, London.
9202. Incandescing Fire-grate Bottom for Stoves, J. D. Wood, London.
9203. Cooking Utensils, S. York and R. I. Knight, London.
9204. Binocular Field, &c., Glasses, J. H. Steward, London.
9205. Stretchers and Ambulances, B. Hardcastle, London.
9206. Ships' Divisional Bulkheads, S. A. Johnson, London.
9207. Increasing Furnace Combustion, H. J. Dowsing, London.
9208. Advertising, D. R. S. Galbraith, London.
9209. Conveying Signals from Railway Stations, &c., to or from Railway Trains in Motion, F. J. Agabeg, London.
9210. Attaching Tires to Wheel Rims, J. W. Bowley, London.
9211. Sanitary Traps for Sinks, &c., H. E. Hadley, London.
9212. Printed Pile Carpet, C. Hughes and W. Youngjohns, London.
9213. Educational Game, C. W. Faulkner and N. Winchcombe, London.
9214. Speed Indicating Apparatus, A. Inokuty, London.
9215. Tool for Bending Bandage Bars, E. Stendel, London.
9216. Coin-freed Meter Apparatus, J. F. Simmance, London.
9217. Transport and Storage of Cycles, J. Oller, London.
9218. Appliance for Supporting Bicycles, F. Sabel, London.
9219. Bulkhead Closer, D. B. Morison and R. Cockburn, London.
9220. Reducing Sulphide Ores of Lead, C. T. Vautin, London.
9221. Protecting the Bottoms of Vessels, J. Gordon, London.
9222. Book or Music Holders, &c., W. J. Pitt, London.
9223. Caissons for Pier Foundations, W. De H. Washington, London.
9224. Stop Valves, J. Hopkinson and J. Lowis, London.
9225. Warming Vehicles, J. and H. E. Gresham, Manchester.
9226. Splints, E. Stendel, London.
9227. Carrying Heavy Books, &c., A. Chapman, London.
9228. Head-rest for Dentists' Chairs, E. Jung, Liverpool.
9229. Tubes for Cycle Frames, &c., C. Binks, Liverpool.
9230. Rims for Wheels for Bicycles, J. T. Hircock, London.
9231. Device for Closing Mouths of Bottles, L. Bouneu and G. de Margeot, London.
9232. Treating Oil, F. B. Aspinall and The Electrical Oil Refining Company, Ld., London.
9233. Gas Meters, H. A. Willey and S. Simpson, London.
9234. Blast Furnaces and Cupolas, O. J. Wilmart, London.
9235. Feed-water for Steam Boilers, A. Montazeau, London.
9236. Coin-freed Mechanism, F. Saunders, London.
9237. Combination Hand Tools, R. Teichmann, London.
9238. Pneumatic Tires for Bicycles, R. Pattison, London.
9239. Stripping Insulation from Wires, W. McMurtrie, London.
9240. Pneumatic Tires for Bicycles, W. F. Goerdes, London.
9241. Garment Hooks, C. C. Blossom, London.
9242. Dentistry, W. L. Mason and H. A. Curtis, London.
9243. Signal Indicators, R. Morris and J. Crabtree, London.
9244. Manufacturing Incandescent Bodies, W. Nicholls, London.
9245. Tipping Buckets, C. Q. Henriques, London.
9246. Dough-notching Knives, M. Dare, London.
9247. Bells for Cycles and other Vehicles, H. Elsom, London.
9248. Filter, J. H. Southcott, O. P. Payne, and J. C. Sunter, London.
9249. Igniting Blasting Charges, H. M. Edwards, London.
9250. Fastener for Coats and Vests, J. Bedford, London.
9251. Hairpins, A. W. H. Barrett, London.
9252. Ladies' Hair-combs, A. W. H. Barrett, London.
9253. Boot Brushes, A. C. Clarke, London.
9254. Brushes for Shaving Purposes, J. Walton, London.
9255. Bicycle Rest or Support, J. Aynsley, London.
9256. Air and Exhaust Valves for Engines, J. B. Petter, London.
9257. Arc Lamps, C. Grahner, London.
9258. Astatic and Dead-beat Galvanometers, T. Clark, London.
9259. Explosion Engines, A. J. Boult.—(*La Société J. Landry and G. Beyroux, France.*)
9260. Machinery for Sifting Flour, E. Trummer, London.
9261. Ventilating Shafts, &c., W. Williams, London.
9262. Distributing Electricity, R. Pippette, London.
9263. Bearings for Wheels, W. H Dunkley, Birmingham.

2nd May, 1896.

9264. Adjustable Hat Peak, R. S. and J. S. Brown, London.
9265. Cycle Rack, W. E. Harper, Bath.
9266. Electric Lighting Fuses, J. MacK. Urquhart and W. H. Dingle, London.
9267. Pressure Gauges, F. Edwards, London.
9268. Utilising Air for Cycles, B. H. Thwaite, London.
9269. Argentiferous Ores, &c., B. H. Thwaite, London.
9270. The Glove Safety Purse, D. H. Thompson, Scarborough.
9271. Cigarette Machine, G. Thompson, Fife.
9272. Water-tight Doors, J. Donald and W. Johnstone, Barrow-in-Furness.
9273. Milking Machines, A. Shiels, Glasgow.
9274. Extinction of Fire, J. H. R. Dinsmore, Liverpool.
9275. Apparatus for Operating Auto-cars, R. Harrison, Herts.
9276. Metal Heads of Golf Clubs, C. Playfair, Belfast.
9277. Apparatus for Hoppling Sheep, J. S. Anthony, Derby.
9278. Tire for Cycle Wheels, &c., J. S. Anthony, Derby.
9279. Collapsible Gates, J. Robertson and J. Watt, Glasgow.
9280. Machines for Checking Time, M. Loftus, Wrexham.
9281. Ascertaining the Temperature of Kilns, C. Copeland, Staffs.
9282. Constructing Auto-cycles, W. H. Eaves, Coventry.
9283. Constructing Auto-cycles, W. H. Eaves, Coventry.
9284. Switching Gear of Electrical Transformers, A. H. Walton, London.
9285. Load Sustaining Hoists, C. J. Hart and B. C. Barton, Birmingham.
9286. Bogies for Railway Vehicles, J. H. Graham, London.
9287. Hinge for Railway Wagon Doors, H. Hyde, Sheffield.
9288. Telephone Receivers, A. Marr, Manchester.
9289. Electro-deposition of Copper, W. E. Heys.—(*E. Dumoulin, France.*)
9290. Ruling Machines, J. Joly, Dublin.
9291. Harrows, F. C. Merrill, London.
9292. Weighing Scales, J. G. J. Davis, London.
9293. Bedsteads for Trapping Insects, G. Ipson, London.
9294. Hat Brim Curl Trimming Machines, G. Atherton, Manchester.
9295. Shaping Sheet Rubber Tubing, W. G. Wrench, Glasgow.
9296. Pneumatic Corks or Stoppers, E. Guthrie, Manchester.
9297. Decorating Fenders, H. E. and E. O. Newey, Dudley.
9298. Decorating Fire-dogs, H. E. and E. O. Newey, Dudley.
9299. Apparatus for Printing Late News, J. H. Watt, Liverpool.
9300. Attaching Collars to Fronts, A. B. Coates, Stockport.
9301. Breaking up Macadamised Roads, P. S. Swan, Arbroath.
9302. Refrigerators, D. B. Walker, Glasgow.
9303. Trawl Nets for Surface Fishing, G. Davidson, Glasgow.
9304. Drinking Troughs for Dogs, S. M. Buchan, Glasgow.
9305. Gas Lamps for Railway Carriages, J. Sharp, Glasgow.
9306. Valves, A. T. Macfarlane, Glasgow.
9307. Controlling Feed-water, A. G. Mumford and A. Anthony, London.
9308. Improved Carrier for Golf Clubs, H. Verschoyle, London.
9309. Hand Cameras, S. Hebblewhite, London.
9310. Transmitting Motion to Parts of Machines, F. W. Farr, London.
9311. Sewing Machines for Boots, &c., F. W. Farr, London.
9312. Dating or other Stamps, J. W. Sutton, London.
9313. Velocipedes, A. P. Blackman, London.
9314. Tea Strainers, A. R. Pritchard, London.
9315. Cocks for Preventing Leakage, C. King, London.
9316. Treatment of Gas, C. E. Botley and C. F. Botley, jun., London.
9317. Props or Stands for Bicycles, W. Parry, jun., Liverpool.
9318. Shoe Heel Paring Machines, W. R. Mudd, London.
9319. Game for Parlour Tables, F. H. Madge, Liverpool.
9320. Measuring Liquids, H. Mayer.—(*C. Mayer, Germany.*)
9321. Sectional Tires for Cycle Wheels, C. Parnacott, London.
9322. Weaving Machinery, — Zubler, London.
9323. Lithographic Reproduction, M. Fischer, Brussels.
9324. Manufacture of Picture Frames, M. Kaelin, London.
9325. Cooking Ranges, G. G. Brodie and J. D. Prior, London.
9326. Furniture for Bed-rooms, &c., H. Cowley, London.
9327. Adjustable Sliding Sight Bar, G. J. Brownnutt, Bucks.
9328. Cycle Chain Gear, W. G. Parry and W. H. Hillsdon, London.
9329. Bottles for Spraying Liquids, M. de Laski, London.
9330. Saddle Cover for Velocipedes, M. de Laski, London.
9331. Pince-nez, &c., F. H. B. Carr, London.
9332. Permanent Electric Ways, A. Rincklake, London.
9333. Cycle Locks, F. W. Godwin, London.
9334. Linotype Machines, T. P. Ritzema, Birmingham.
9335. Carriages, Count A. de Dion and G. Bouton, London.
9336. Explosion Motors, Count A. de Dion and G. Bouton, London.
9337. Petroleum or Gas Engines, Count A. de Dion and G. Bouton, London.
9338. Gear Wheels, Count A. de Dion and G. Bouton, London.
9339. Cycle Pedals, E. W. Fraser, Bromley-by-Bow.
9340. Blackboards, L. Lahrmann, London.
9341. Fountain Pens, R. W. Barker.—(*E. Frischknecht, United States.*)
9342. Flying Machines and Apparatus, H. Middleton, Slough.
9343. Dyestuffs, O. Imray.—(*The Farbwerke vormals Meister, Lucius, and Brüning, Germany.*)
9344. Tapping Casks, J. H. McCullough and R. Crawford, London.
9345. Antiseptic Preparations, &c., J. Ascough, London.
9346. Billiard Ball Returner, W. Buttery, London.
9347. Handles for Cycles and Vehicles, J. McRae, London.
9348. Pneumatic Tires, B. P. and D. W. Alexander, London.
9349. Electrical Measuring Device, H. A. Rowland, London.
9350. Wearing-edge Protectors, &c., W. Hoffmann, London.
9351. Dredging Pipe Sewers and Drains, E. Murray, London.
9352. Mattresses, J. Sibley, London.
9353. Moulding Screw-stoppered Bottles, C. Gray, London.
9354. Stoppering Devices, A. J. Boult.—(*L. Bouneu, Belgium.*)
9355. Compressing Device for Moulding, C. H. Gray, London.
9356. Treating Defective Sight, C. Dion and Y. A. M. P. Goubaux, London.
9357. Packing Food, H. H. Lake.—(*Vacuum Pan and Jar Co., United States.*)
9358. Apparatus for Producing Carbite, R. Pictet, London.
9359. Raising and Stacking Hay, &c., H. Reeves, London.
9360. Velocipede or Cycle Pedal Motion, M. Bliss, London.
9361. Closets, M. J. Adams, London.
9362. Dynamo-electric Machines, W. B. Sayers, London.
9363. Stoves, E. Laroche, London.
9364. Skates, E. O. Friederich, Germany.
9365. Perforating Machines, W. C. Barns and E. Selby, London.
9366. Producing and Burning Vapour, R. Poitrimol, London.

4th May, 1896.

9367. Control of Cycles, G. Quick, London.
9368. Maritime Vessels, W. P. Thompson.—(*W. R. Brüner and F. L. Anderson, United States.*)
9369. The Locke Cycle, S. H. Locke, Heaton Moor, Lancashire.
9370. Construction of Beetling Engines, J. W. Frazer, Belfast.
9371. Universal Advertising Letters, G. J. Gillett, Charlbury, Oxon.
9372. Pneumatic Tubes, W. R. and W. Swinburn, Great Grimsby.
9373. Coin-freed Machinery, G. Salter, Birmingham.
9374. Apparatus for Filtering Sewage, W. Birch Manchester.
9375. Locking Window Fastenings, G. Ashton, Manchester.
9376. Construction of Toy Puzzles, E. Taylor, Blackburn.
9377. Cycles, W. T. Smith, Keighley.
9378. Tobacco Pipe, J. O. Martinson and J. B. Archer, South Shields.
9379. Gas Motors, T. Bush, Coventry.
9380. Expanding Reels or Drums, R. Wallwork, Manchester.
9381. Pneumatic Hammers, E. Samuelson, Banbury, Oxon.
9382. Attachment Bosses of Cycle Saddles, J. B. Brooks, Birmingham.
9383. Propellers for Steam Ships, F. Wakefield, Birkenhead.
9384. Cotton Blanket Sheet, A. Warburton, Manchester.
9385. Joints for Tramway Rails, W. E. Kenway, Birmingham.
9386. Band for Sewing Machines, C. A. McCombie, London.
9387. Cycles, J. Melling, London.
9388. Obtaining Copper from Copper Ores, C. A. Burghardt and G. Rigg, Manchester.
9389. Handles for Cycles, S. Whittaker and G. H. Richmond, Manchester.
9390. Rotary Cutting Machines, A. Muir and H. S Clement, Glasgow.
9391. Rulers, G. M. Davies, Cardiff.
9392. A Novel Game, A. G. Rowlett and C. W. Faulkner, London.
9393. Stud Extractor or Driver, W. L. Wynn, Birmingham.
9394. Cutting Out Leather, J. Blakely and W. F. Blampey, Halifax.
9395. Apparatus for Winding Certain Warps, J. Rhodes, Bradford.
9396. Bicycle, R. Flucke, Berlin.
9397. Shot Register for Fire-arms, P. Gehlich, Berlin.
9398. Pulleys, W. Snelgrove, Birmingham.
9399. Air Tube for Pneumatic Tires, T. J. Rickard, Newport, Mon.
9400. Shuttle Guard for Looms, F. W., A., and J. Jepson, Burnley.
9401. Combined Shirt and Drawers, C. E. Corfe, Winchester.
9402. Electric Gas Lighting Devices, O. von Morstein, London.
9403. Cap Spinning, &c., Machinery, M. Crossley, London.
9404. Flushing Water-closets, J. and C. Wilby, London.
9405. Trap for Catching Rats, E. G. Kendall, Birmingham.
9406. Tires, A. Mapplebeck, Birmingham.
9407. Water-closets, J. Duckett and Son, Ld., and J. Duckett, London.
9408. Galvanising Iron, E. Rousseau, Catford Bridge.
9409. Hand Vices, J. W. S. Neal, London.
9410. Lanterns, J. Tabrar, London.
9411. Spring Wire, T. Shepherd. London.
9412. Flower Holder or Clip, W. S. Tansley, London.
9413. Automatic Reference Paper, A. A. M. Fournet, London.
9414. Saddle Covers, The Eadie Manufacturing Company, Ld., and H. J. Milward, Birmingham.
9415. Escapement for Watches, F. Scherzinger, London.
9416. Appliances for Drain Pipes, J. A. Kershaw, London.
9417. Cooking Utensils, J. H. Trinder, Surrey.
9418. Lock and Hasp, S. R. Foreman and G. A. Askew, London.
9419. Grindstones, F. A. Ziegner, London.
9420. Infusers, E. Fowler, London.
9421. Device for Fixing Curtain Poles, F. A. Müller, London.
9422. Applying Strips to Box Corners, H. Inman, London.
9423. Floats for Supporting Weights, E. L. Berthon, London.
9424. Converting Horizontal into Rotary Motion, J. H. Nelson and A. E. Freeto, London.
9425. Puzzles, W. M. Williams, London.
9426. Bottles, F. E. d'Humy, London.
9427. Pencil Holders, A. P. Gillespie, London.
9428. Devices for Spreading Shoes, P. Fournier, London.
9429. Accommodation Skirt, &c., F. Hooper, London.
9430. Heating of Laundry Irons, C. Stephens, London.
9431. Lifts, G. Zahikian, London.
9432. Preventing Overheating of Shafts, M. Evans, London.
9433. Umbrella Frames, E. W. Golby.—(*F. Prager, Germany.*)
9434. Dress Coverings, M. Moscovitz, London.
9435. Cycle Locks, T. Baxter, Liverpool.
9436. Mechanism for Operating Auto-cars, J. G. Horsey, London.
9437. Knee or Bed Covers for Trains, &c., M. Bliss, London.
9438. Mechanism of Linotype Machines, The Linotype Co., and C. L. Ireland, London.
9439. Knives, J. F. Wilke, London.
9440. Velocipedes, H. J. Kloos, London.
9441. Attaching Wallets to Cycles, F. Weintraud, London.
9442. Tricycles, P. Dorigny, London.
9443. Show Cases for Cabinets, H. Broughton, London.
9444. Balloons, &c., H. Broadbent and A. Swan, London.
9445. Trucks, H. A. L. Barry, London.
9446. Cocks, E. H. Page, London.
9447. Reversible Variable Speed Gear, A. G. Cooke, London.
9448. Centrifugal Pumps and Ventilators, F. Pelzer, London.
9449. Door Fastening, J. Haswell, London.
9450. Apparatus for Spraying Liquids, G. S. Spurrier, London.
9451. Presses for Bundling Hay, W. J. Perkins, London.
9452. Inhaler, A. M. Paddon, C. E. Hedmondt, and H. L. Pringle, London.
9453. Wheeled Vehicles, &c., Sir A. H. Grant, Bart., London.
9454. Steam Engines, C. Bellens, London.
9455. Biscuit for Human Food, B. F. Hartzhorne, London.
9456. Tool Rest, J. F. Lorenz and H. Leistner, London.

5th May, 1896.

9457. Garden Chair, D. S. Hawks, Welshpool
9458. Feeding Bottle Holder, G. Royle, Bedford.
9459. Velocipede, W. Wingate, London.
9460. Bicycle Chains, J. Hollis, Ilkeston.

9461. Radiographic Vacuum Tube, J. Buckland, Taunton.
9462. Keeping Tobacco Moist, C. and L. W. Lee, Bilston.
9463. Motor Power for Velocipedes, F. T. Pritchard, Leamington Spa.
9464. Tea Strainers, W. H. Pike, Cardiff.
9465. Letter-box Plates and Letter-boxes, E. Miles, Swansea.
9466. Water Telescope, G. Hopkins and R. W. Archer, Reading.
9467. Boots for Animals, F. H. Ayres and R. Evans, London.
9468. Shoulder Pads for Coats, &c., W. H Sladdin, Brighouse.
9469. Bottle with Self-locking Lock, W. Sherwood, Birmingham.
9470. Cycle Frames, F. S. Willoughby, Manchester.
9471. Igniting Cigarettes and Cigars, E. Guthrie, Manchester.
9472. Cycle Mud-guards, E. D. Hopcroft, Kidderminster.
9473. Attaching Heels to Shoes, W. H. Dorman, Stafford.
9474. Folding Sheets of Paper, K. Geiger, Manchester.
9475. Skimming Molten Iron, H. Gerling, Birmingham.
9476. Crane Apparatus for Elevating Buckets, S. Porter, Liverpool.
9477. Dyes, L. P. Marchlewski, E. S. Wilson, and E. Stewart, Liverpool.
9478. Frame for Christmas Cards, W. Jones, Newport, Mon.
9479. Cycles, G. O'C. Holloway, Birmingham
9480. Subways, A. S. Krotz, W. P. Allen, and O. S. Kelly, Manchester.
9481. Gas Meters, G. H. Smith, Manchester.
9482. A New Tire for Cycle Wheels, J. Blakey, Halifax.
9483. Double Cased Oven Doors, W. E. Jaques, Salop.
9484. Steel Wire Suspender, &c., W. J. Byard, Bradford.
9485. Lubricators, C. Ankers, Liverpool.
9486. Fire Lighters, E. Jones, Bradford.
9487. Brushes for Cleaning Cycles, G. and H. Zierlien, Halifax.
9488. Picker Spindles of Weaving Looms, J. Appleyard, Bradford.
9489. A Toy, J. H. Ruddick, Newcastle-on-Tyne.
9490. Manufacture of Cricket Balls, J. Lane, London.
9491. Railway Permanent Way Chairs, F. G. Hopkirk, Belfast.
9492. Hammerless Gun Locks, O. Horton, Glasgow.
9493. Photographic Cameras, &c., E. Wood, Rochdale.
9494 Steam Valves, J. C. Jackson and J. Ogden, Manchester.
9495. Spinning Frames, S. M. Rutnagur, Manchester.
9496. Pneumatic Tires, P. A. Birley and C. Macintosh and Co., Ltd., Manchester.
9497. Improved Window Fastener, R. Ellis, Lancashire.
9498. Removing Liquids in Kettles, S. Diplock and W. T. Lalonde, Weston-super-Mare.
9499. Combustion of Gases, S. Diplock and W. T. Lalonde, Weston-super-Mare.
9500. Spanners and Wrenches, G. F. Forster, Liverpool.
9501. Ladies' Blouses, L. S. Willoughby, London.
9502. Flat Printing Presses, T. E. Allison, London.
9503. Reversible Octave Concertina, F. A. Hanks, London.
9504. Three-way Railway Switch, S. C. Adams and H. P. Crouse, London.
9505. Bottles, J. S. Harrison, London.
9506. Spring Heel for Boots, &c., H. D. Richey, London.
9507. Ball Bearings, F. W. Engels and H. R. Kirschbaum, London.
9508. Cycle Crank Attachments, F. W. Engels and H. R. Kirschbaum, London.
9509. Letter Carriers' Register, J. D. Miller, S. M. Jones, and C. M. Towson, London.
9510. Photographic Burnishers, G. C. W. Gennert, London.
9511. Vent Plug for Barrels, G. H. W. Davis, Birmingham.
9512. Shedding Motions of Looms, T. Crook London.
9513. Coop for Fattening Geese, M. Rosenberger and F. Belággi, Birmingham.
9514. Casting Ingots, W. Kirkham and D. Evans, Sheffield.
9515. Pneumatic Tires, C. Lyon and C. Poose, London.
9516. Appliances for Testing Sight, N. Davidson, London.
9517. Railway Signalling, W. R. Sykes and F. T. Hollins, London.
9518. Reaching Elevated Parts of Buildings, E. J. Palmer, London.
9519. Machines for Drawing Corks, W. Vaughan, Birmingham.
9520 Improved Night-dress for Children, L. High, London.
9521. Artificial Musk, S. S. Bromhead.—(*Messrs. Gretsch and Mayer, United States.*)
9522. Thread Cutting Implements, C. Elterich, London.
9523. Mouse Traps, N. Fellows and H. S. Stacy, London.

9577. Treating Auriferous Slimes, J. H. Pollok, London.
9578. Making Lucifer Matches, J. C. Donnelly, Liverpool.
9579. Pneumatic Tires, H. S. Maxim, London.

6th May, 1896.

9580. Combined Manhole Filter and Dirt-box, J. T. Neech, Tyldesley, near Manchester.
9581. Antiseptic Animal Size, F Humphrey, Bristol.
9582. Antiseptic Mineral Size, F. Humphrey, Bristol.
9583. Antiseptic Clair Colle, F. Humphrey, Bristol.
9584. Pneumatic Cycle Seat, J. A. Bonds, L. Dawes, and S. Dawes, London.
9585. Graduated Handrail Wreath Measure, W. J. and I. Harrison, Derbyshire.
9586. Brackets for Rain Water Gutters, A. Doman, Dudley.
9587. Water-tube Boiler, S. J. Hamblin, Newbury.
9588. Detachable Covers for Tires, W. D. Mastaglio, Newcastle-on-Tyne.
9589. Shaft Governors, F. Bosshardt.—(*J. R. Frikart, Germany.*)
9590. Breast-strap for Weaving Looms, H. Spencer, Blackburn.
9591. Wet Gas Meters, H. O'Connor, Edinburgh.
9592. Tires of Vehicles, W. Menzies, Dundee.
9593. Sewing Sweat Hat Bands, J. Kelso.—(*A. Kelso, United States.*)
9594. Tires for Cycle, &c., Wheels, J. A. Beattie, Glasgow.
9595. Tandem Cycles, G. W. Bendie, Glasgow.
9596. Cog-wheel Driving Bands, G. Moore, jun., Birmingham.
9597. Handle-bars of Cycles, A. G. and H. H. C. Adamson, Glasgow.
9598. Corsets, E. Young, Glasgow.
9599. Artificial Fuel, R. Bradshaw, Liverpool.
9600. Blowing Apparatus, T. Duncan, Oldham.
9601. Decorating Glass for Leaded Lights, E. W. Brock, Bristol.
9602. Sewage Precipitation Tanks, H. Walker, Nottingham.
9603. Preparation for Glazing Linen, M. Holding, Halifax.
9604. Liquid Container, G. H. Shaw, Ashton-under-Lyne.
9605. Ladies' Skirts for Cycling, M. A. Ward, Bristol.
9606. Lighter for Cigars and Pipes, J. G. Squire, London.
9607. Lessening Carriage Vibration, J. Annandale, Glasgow.
9608. Sewing Machines, W. H. Inslee.—(*The Singer Manufacturing Co., United States.*)
9609. Igniting Cigarettes and Cigars, E. Guthrie, Manchester.
9610. Fire-engines, J. C. Merryweather and C. J. W. Jakeman, London.
9611. Tyres for Cycles and Vehicles, H. Thompson, London.
9612. Breaking Up Dried Fruits, T. Johnson, London.
9613. Combination Folding Tent and Bed, J. Long, London.
9614. Power Hammers, W. H. Botting, London.
9615. Ironing Machine, W. Lanfear and G. A. Macdonald, London.
9616. Bicycle Support, R. C. Mann, London.
9617. Powder for Cleaning Teeth, J. Berman, London.
9618. Aprons and Rugs for Vehicles, &c., H. G. Ives, Bristol.
9619. Electric Lamps, S. P. Eastick and E. Sayer, London.
9620. Socket Connection for Pipes, &c., F. Offen, London.
9621. Cartridge Holders, H. S. McKenzie, London.
9622. India-rubber Waterproof Fabrics, T. Birnbaum, London.
9623. Cycle Driving Gear, J. Greenall and A. Jones, London.
9624. Cycle Tires, J. Whitehead and J. A. Crane, Handsworth
9625. Locks, Sir G. H. Chubb and G. G. Exton, London.
9626. Rotary Blowers or Exhausters, T. W. Green, London.
9627. Feeding Ore to Crushing Machines, The Sandycroft Foundry and Engine Works Company, Ld., and R. O. Ahlers, London.
9628. Elastic Tire for Velocipedes, Sir H. W. Tyler, London.
9629. Separating Paper Sheets, A. S. Coghill, London.
9630. Combustion of Acetylene Gas, C. Coppeaux, London.
9631. Churning, Whisking, Mixing, &c., P. Dutto, London.
9632. Friction Gear Hoisting Apparatus, R. F. Sturrock, London.
9633. Metal Capsules, B. J. B. Mills.—(*E. Stern, France.*)
9634. Luggage Carriers, A. J. Boult.—(*The Rochester Bicycle Combination Holder Company, United States*)
9635. Protectors for Sink Pipes, &c., J. Gowland, London.
9636. Producing an Optical Delusion, E. Prentice, London.
9637. Arc Lamps, A. Blahnik, London.
9638. Pulleys for Transmitting Power, J. H. Lee, London.
9639. Guard for Cricket, J. G. and W. A. Green, London.
9640. Spindles of Spinning Machines, C. Bergmann, London.
9641. Bicycles, &c., H. Gläser and R. Kolbaba, London.
9642. Pneumatic Tires, W. A. G. Birkin, London.
9643. Wheels for Cycles, &c., T. W. N. Crawford, London.
9644. Fittings for Lavatory Basins, O. Elphick, London.
9645. Bulbs for Producing Rays, R. M. Deeley, London.
9646. Softening Water, E. d'Huart, and M. and G. Glaesener, London.
9647. Hat Boxes for Silk Hats, F. W. Longmore, London.
9648. Roller Skates, W. P. Thompson.—(*H. Strieffler, Germany*)
9649. See-saw, W. P. Thompson.—(*E. Schneider, Germany.*)
9650. Electromotors and Dynamos, E. Lanhoffee, London.
9651. Cloak, H. A. Meyer, Liverpool.
9652. Valves, &c., L. H. Jung and H. A. Clifton, London.
9653. Pumps, Valve Guards, &c., F. Edwards, London.
9654. Framing for Bedsteads, P. Jensen.—(*H. J. Kollén, Sweden.*)
9655. Dry Docks, W. W. Horn.—(*A. Cameron, United States.*)
9656. Depositing Metal, The Improved Electric Glow Lamp Syndicate, Ld.—(*C. Schwabe, Germany.*)
9657. Attaching Tires to Rims of Wheels, S. Chandler, jun., and J., J. C., and S. B. Chandler, London.
9658. Drying Butter, R. A. Lister and G. E. Snoxell, London.
9659. Seed and Manure Drills, &c., J. Wilson, London.
9660. Let-off Motions for Looms, J. Poyser and F. L. Ball, London.
9661. Extinguishing Fires, &c., J. M. Raymond, London.
9662. Headlocks for Cycles, V. F. and W. F. Drew, London.
9663. Bottle Case, H. Penn, London.
9664. Bolt, J. W. Sutton, London.
9665. Apparatus for Drying Materials, E. Stauber, London.
9666. Pneumatic Tires, H. S. Maxim, London.

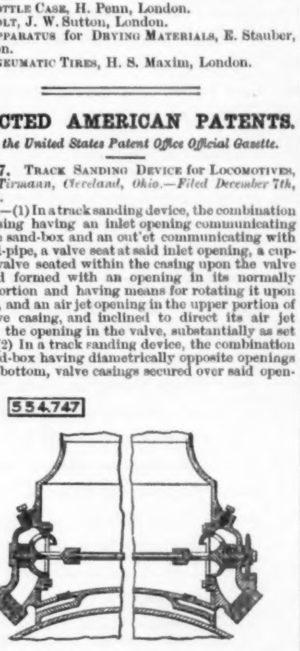
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

554,747. Track Sanding Device for Locomotives, *H. Tirmann, Cleveland, Ohio.—Filed December 7th*, 1895.

Claim.—(1) In a track sanding device, the combination of a casing having an inlet opening communicating with the sand-box and an outlet communicating with the sand-pipe, a valve seat at said inlet opening, a cup-shaped valve seated within the casing upon the valve seat and formed with an opening in its normally upper portion and having means for rotating it upon the seat, and an air jet opening in the upper portion of the valve casing, and inclined to direct its air jet through the opening in the valve, substantially as set forth. (2) In a track sanding device, the combination of a sand-box having diametrically opposite openings near its bottom, valve casings secured over said openings and formed with inlet openings communicating with the sand-box and outlets communicating with the sand-pipes, valve seats at the inlet openings of the casings and having inwardly overhanging hoods at their upper portions, cup-shaped valves upon said seats having pivots journalled in the valve casings and formed with openings in their normally upper portions and with inwardly projecting shanks formed with openings which register with said first mentioned openings, springs which force said valves upon their seats, a rod having its ends attached to the shanks of the valves, and air jet chambers in the upper portions of the valve casings and formed with inwardly inclined jet openings, substantially as set forth.

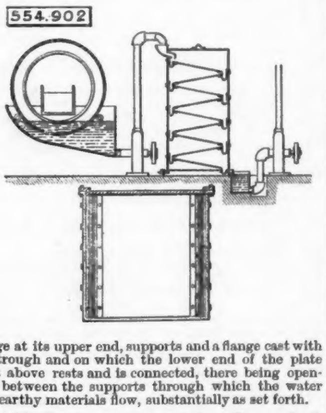
554.747



554,902. Amalgamator for Separating and Saving Gold, *T. G. Barlow-Massicks, Prescott, Ariz.—Filed January 23rd*, 1895.

Claim.—The combination in an amalgamating apparatus, of the cast iron troughs, each with an upwardly-projecting flange at one side and an inclined flange at the other side, an inclined plate, fastened to such flange at its upper end, supports and a flange cast with the trough and on which the lower end of the plate next above rests and is connected, there being openings between the supports through which the water and earthy materials flow, substantially as set forth.

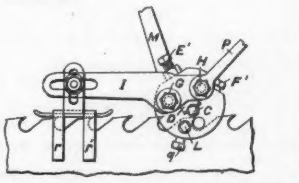
554.902



555,005. Device for Swaging Saw Teeth, *S. H. Holley, Marquette, Mich.—Filed July 3rd*, 1895.

Claim.—In a device for swaging the points of saw teeth, the combination with body A, provided with slot J; anvil B, held in position by set screws F and F'; die C, block D, in slot O, provided with groove *a* and set screws E and E', and handle N; set screw K, with small set screw *q*; set screw L, with handle M; guide I having slot *u*, held to body A by bolts H and G; with finger U and rest S, held to guide I by bolt V; finger U being provided with guards and extensions *r*, *r'* and *r*² and slot *u'*; and stop P; all substantially as shown and described.

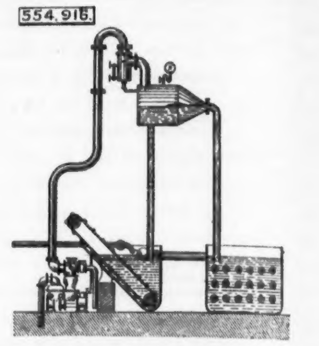
555.005



554,916. Vacuum Pan, *H. H. Dow, Midland, Mich.—Filed June 13th*, 1895.

Claim.—In apparatus for producing granular salts or similar solid substances from liquids by evaporation, the combination of an open heating vessel provided with means for heating the liquid therein, and thereby separating and depositing the less soluble impurities accessible for removal, and elevated separating vessel having a pipe ascending into it from the heating vessel and having a descending pipe from its bottom, means for reducing the atmospheric pressure in said separating vessel to raise the liquid from the heating vessel into the separating vessel and to produce evaporation without the application of heat to said latter vessel, and a settling vessel having the descending pipe opening into it and from which the settled solids may be removed, substantially as set forth.

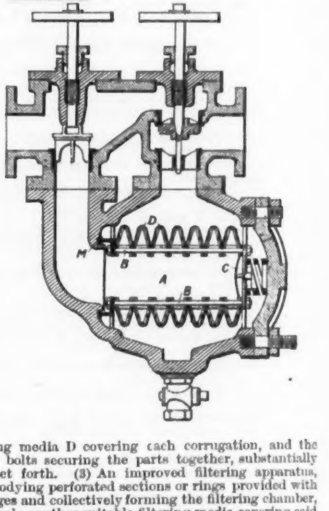
554.916.



555,020. Filter, *W. Railton and R. Campbell, Liverpool, England.—Filed April 30th*, 1894.

Claim.—(1) An improved filtering apparatus, embodying a filtering chamber formed of the perforated corrugated sections or rings having flanges, the end pieces C C, longitudinal stay bolts B passing through said flanges and end pieces, the seating M against which one set of end pieces C rest, and tightening devices for forcing the filtering chamber against said seating, substantially as and for the purpose set forth. (2) An improved filtering apparatus, embodying the perforated corrugated sections or rings forming the filtering chamber A, the filtering flannels or other filtering media D covering each corrugation, and the stay bolts securing the parts together, substantially as set forth. (3) An improved filtering apparatus, embodying perforated sections or rings provided with flanges and collectively forming the filtering chamber, flannels or other suitable filtering media covering said perforated sections and having the edges clipped between the flanges of the adjoining sections or rings, and bolts passing through said flanges for securing the sections or rings together and binding the covering or filtering media in position, substantially as set forth.

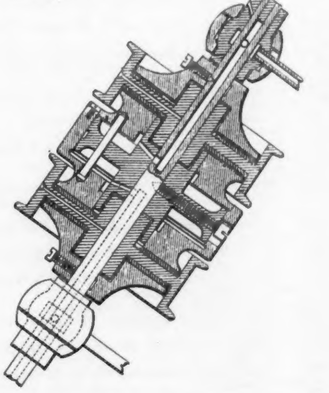
555.020



555,036. Fluid Controlled Clutch Mechanism, *D. H. Church, Newton, Mass.—Filed July 20th*, 1895.

Claim.—The combination with a shaft, a pair of pulleys thereon, and means for resisting movement of said pulleys longitudinally of the shaft; of a single closed cylinder embracing the shaft between the pulleys, a piston in the cylinder, and channels for admission of fluid under pressure into the cylinder on either side of said piston, one of said last mentioned parts being held from longitudinal movement and the other constituting a one piece double faced clutch member to engage the pulleys under longitudinal movement—the admission of fluid on one or the other side of the piston effecting a clutching of one pulley and at the same time a positive unclutching of the other pulley.

555.036



ON THE TRANSMISSION OF HEAT THROUGH METAL PLATES FROM HEATED GAS AT THE ONE SIDE TO WATER BEING HEATED AND EVAPORATED AT THE OTHER.

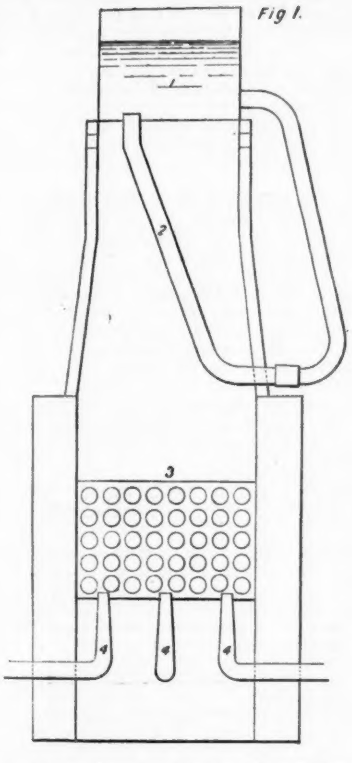
By Mr. A. BLECHYNDEN.

THIS may be regarded as part of a continuation of that on the same subject by the author, and read at the summer meeting of the Institution of Naval Architects at Cardiff, July 12th, 1893, and is an account of some further experiments on the transmission of heat through metallic plates. The object in view was to ascertain how the rate of transmission of heat through copper plates compares with the rate of transmission through steel plates of the same thickness and under the same condition.

The apparatus employed in most of the experiments was identical with that described in the previous paper as having been employed in the experiments with the steel plates, and for a description reference may be made to that paper; in other cases an almost entirely different apparatus was used. The experiments whose results are given in tables 1, 2, 2A, 3, and 3A, were made with the identical apparatus previously used.

The experiments with the copper plate P, and the steel plate G, of which the results are given in Table 4, were made with the furnace as originally described. The plates formed the bottoms of two semicircular pans, each 5in. radius, and so made that they could be placed together side by side and form one circle of the same diameter as the original boiler. Each plate was ·08in. thick, and their surfaces were as nearly as possible of equal smoothness; but while the copper plate had a clean metallic surface, that of the steel plate was oxidised. The tubes K and L were experimented upon with the apparatus shown in Fig. 1. Into each of the semicircular pans just described a tube was fitted, as shown in Fig. 1, the one end being connected to the side and the other to the bottom. The tubes were partially in and partially out of the furnace; the inner part forming the upcast, while the outer formed the downcast tube. The tubes were solid drawn, 1·1875in. diameter outside and ·09375in. thick. K was of steel and L was of copper.

Fig 1.



The copper plate I was a piece of boiler plate, such as is used for the fire-box of a locomotive. Its surfaces were smooth and clean, just as they had left the rolls. B was a Siemens-Martin steel boiler plate. The side which was next the water was machined, but the lower side was left untouched.

For the method of experimenting with the plates, reference may be made to the paper above referred to. The experiments with two semicircular fans were carried out in a somewhat similar manner to those with the circular plates. The time required to reach the boiling point was noted, as well as the evaporation in a given time, so that there were two records to check the relative rates at which heat was transmitted by the two plates. For all practical purposes the experiments with the two tubes, K and L, were conducted in the same manner.

The furnace temperatures were estimated by means of a Siemens pyrometer, Pouillet's determination of the specific heat of platinum being the basis; for the other temperatures mercurial thermometers were used. The remarks in the previous paper hold good in regard to sources of error. The results of the various series of experiments are given in the accompanying tables and diagrams. Tables 1 and 3 are for a series of experiments with the copper plate I; No. 1 being with the surfaces thoroughly clean, No. 3 with them slightly smoked with the products of combustion from the furnace, and No. 3A with the surfaces thoroughly sooted. Table 2 is a copy of Table 6 of the paper read at the summer meeting of the Institute of Naval Architects in Cardiff, 1893, and is introduced for comparison of the plate I with the plate B, which was the same thickness. Table 2A gives the results of experiments with a steel plate H, which was of the same thickness as the plates I and B, but was machined very smoothly on both sides, almost bright on the fire side, so as to present a clean metallic surface to both sides of the furnace and water, somewhat similarly with the plate E of the Cardiff paper. The surfaces were, however, brighter than those of the plate E. Experiments were also made with this plate with its fire surface smoked as shown in the table. The effect of its greater smoothness was to reduce its rate of absorption much below one with a surface like E. Table 4 gives the comparative results of the thin steel and copper plates placed over the same fire. Tables 5 and 6 give the results of steel and copper in the form of tubes placed in the same fire.

NOTE.—The differences of time under the head of "Duration of experiment" for each experiment are due to their having been measured from the moment the water reached boiling point in each pan. They ended at the same time. In the case of the copper plate, therefore, as it transmitted heat less rapidly than the steel plate, the water in the pan P was longer in reaching the boiling point, which left less time for actual evaporation.

An explanation of their origin may be interesting, as the experiments with the steel and copper plates seem like going over old ground. The first experiment with the copper plate I arose through a discussion as to the advisability of adopting copper in place of steel in the fire-box of a locomotive form of marine boiler. It was suggested that copper should be used, on the ground of its superior conductivity; but as the matter was open to doubt, notwithstanding the fact that it has been often asserted, and even in recent years, that copper is much superior as a heat conductor in the form of a plate to steel, it was determined to test it. Accordingly a single experiment was made, when it was found that the modulus of conductivity, or:—

$$\frac{\text{Heat transmitted per square foot per hour}}{(\text{Difference of temperature on the two sides})^2} = \cdot 015$$

which, being compared with that for a steel plate B of the same thickness, viz., ·024, appeared exceedingly low, and on this account the accuracy of the experiment was doubted.

It will be remembered that Weidmann gives the relative conductivities of copper and iron as 74 and 12, and that Despretz gives the more moderate ratio of 897 to 374. Both these experimenters refer to the internal conductivities only, but as the surface resistance enters the problem of the heat transmission through a plate forming part of the heating surface of a boiler, the problem becomes somewhat more complicated.

Rankine, using Peclet's figures, has given in his "Treatise on the Steam Engine" formulæ and figures for the purpose of estimating the external and internal resistance of a plate of metal to the transmission of heat, and consequently its rate of transmission. The rates thus calculated per hour per square foot of surface for plates 0·5in. thick, the surfaces being assumed as smooth and metallic in the first, and as coated with lampblack in the second case, and for a difference of temperature of 1000 deg. Fah. between the two sides, are for:

	Clean surface.		Lampblack surface.	
Copper ...	... 3415	...	8240	British thermal units, and for
Iron ...	... 3390	...	8230	,, ,,

The difference between these figures for the two metals is sufficiently unimportant to permit of their being regarded as equal, and given as they are on such authority, similar calculations have caused it to be generally accepted that the rate of transmission is little affected by the metal *per se*. As will afterwards be shown, this view is upheld by the experiments whose results are herein given. At the same time many persons have held to the opinion that so long as the surfaces are clean, a copper plate is a better conductor than steel or iron, but that they practically become equal when their surfaces are sooted.

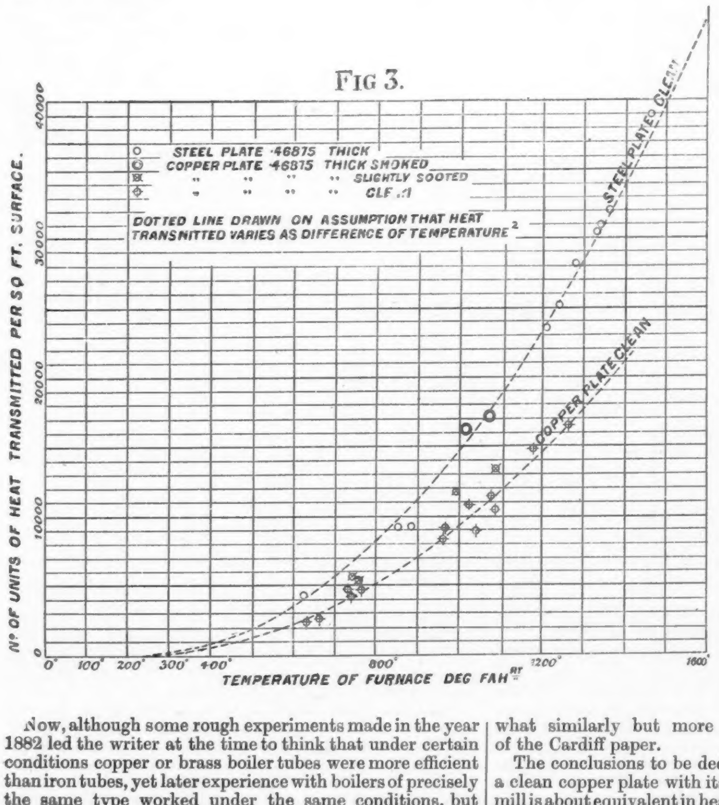
FIG 3.



Now, although some rough experiments made in the year 1882 led the writer at the time to think that under certain conditions copper or brass boiler tubes were more efficient than iron tubes, yet later experience with boilers of precisely the same type worked under the same conditions, but some having brass and others iron or steel tubes, forced upon me the conviction that there was no advantage under ordinary conditions of working, so far as heat transmission was concerned, in brass over iron or steel. He was, therefore, inclined to think that the view generally held, viz., that so long as the surfaces were clean, copper was superior to iron or steel, might be correct, but that such superiority disappeared in the case of sooted surfaces. It was, therefore, a matter of some surprise to find such a marked inferiority of copper to steel indicated in the experiment. And thinking that there might be some error in the measurements of the temperatures, it seemed the most sound and certain means of obtaining comparative data to place two vessels, the one with a copper and the other with a steel heating surface, over the same fire, when, let the temperature be what it might, or the temperature measurements err as they might, the comparative results would be accurate. Accordingly, the two semicircular pans described were made and placed over the same fire, when the fact indicated by the previous experiment was fully confirmed. This will be evident by an examination of the two first lines of Table 4, the moduli being, for

Copper	·01447, and for
Steel	·02120

On a second trial with the same apparatus, however, it was found that a change had taken place in the conditions, and that the modulus of the copper plate had materially altered, having increased to ·01955.

An examination of the surfaces of the plates having shown that both had become sooted, it appeared that the slightly oxidised though comparatively bright surface of the steel plate in the first instance was not equivalent to the clean metallic surface of the copper plate, and that while a coat of lampblack might make a considerable difference in the case of a clean copper plate at least, its influence was not great in the case of a steel plate with its surface in the condition it leaves the mill. To test this point the systematic series of experiments of Tables 1, 2A, 3, and 3A were made.

The series Nos. 1, 3, and 3A were made with the plate I. In the case of No. 1, the surface of the plate next the fire was kept clean, but not polished; in No. 3 the surface was slightly smoked, and in No. 3A it was well sooted. The series whose results are in Table 2A were made with a steel plate, with both its surfaces smoothly machined somewhat similarly but more smoothly than the plate E of the Cardiff paper.

The conclusions to be deduced from these facts are that a clean copper plate with its surfaces as it comes from the mill is about equivalent in heat-transmitting power to a steel plate with its surfaces machined like the plate E, or, that in the case of these two metals at least, clean metallic surfaces are about equal in heat-transmitting properties irrespective of the metal; that the oxidised though comparatively bright surface of the steel plate is approximatively equivalent to a fire and soot dirtied copper plate; that, additionally, soot-dirtying a steel plate whose surface is as from the mill makes little difference in its heat-transmitting properties; and that merely sooting a machined steel plate affects its rate of transmission very little—see Table 2A. The results of the experiments just referred to are further emphasised by those with the tubes K and L, given in tables 5 and 6.

In the first two lines of Table 5 it will be seen that the moduli of the tubes are ·0203 and ·0157 respectively, and that in the remainder of the experiments they apparently fall. The reason of this is because the temperature of the furnace was measured at the upper station only in the first two experiments, but in the remainder it was measured at the lower station as well. The first two moduli only are therefore comparable with those of the plates, as in their case the temperatures at the lower station—14—are not recorded. (See note on this point in Cardiff paper.)

Now, on examination of the values of H ÷ D^2, it will be evident that as the experiments proceed there is a gradual though somewhat irregular approach to equality, evidently due to a slight deposit of soot on the surfaces, as was also found in the case of the plate I.

With the object of further verifying this view, the tubes were sooted as was done in the case of the plate I, and further experiments were made, whose results are given in Table 6. The average of the moduli indicate that while the modulus of the steel plate remained as before, that for the copper increased considerably, the said averages being for copper ·01536, and for steel ·01392. A comparison was also made with a brass tube, a welded steel, and a welded iron tube in an apparatus similar to that illustrated in Fig. 2, with the results that for the differences of temperature of 1700 deg. and 800 deg. Fah., at the ends of the tubes the rates of transmission were for the brass tube, 7600 British thermal units; for the iron tube, 11,800 do. do.; and for the steel tube, 10,000 do. do. per square foot per hour, the surface being measured on the inside of the tubes. It seems clear that the difference in the performance of the tubes is due simply to a condition of surface. The brass tube was clean and metallic, the steel and iron tubes were coated with oxide, but the steel one was much smoother than the iron.

It appears evident, therefore, that these experiments uphold Peclet's views, that the great difference between the efficiency of copper and steel plates found in the first experiments was only due to the difference between their surfaces, which view is upheld by the experiments with the plate E—see tables 12 and 13 of the Cardiff paper—and also by a steel plate of the same thickness as I and B, with its sides machined similarly to E, whose nominal modulus H ÷ D^2 was found to be about ·0148, or just equal to that found for the plate I; its true modulus H ÷ D*d* was ·011.

Now by actual experiment the heat transmitted by copper and steel plates of ·46875in. thickness, both having clean metallic surfaces, and for 1000 deg. Fah. difference of temperature, are:—

Surface.		Clean metallic.		Copper sooted steel as from mills.	
Copper	... ...	11,200	...	18,100	British thermal units
Steel	... ...	11,000	...	18,000	,, ,, ,,

In other words, they are equal in efficiency, but their rates appear very much greater than estimated by Peclet. It also appears from these and the former experiments that the rate of transmission follows the square of the difference of the temperatures much more closely than Peclet thought.

THE PROBLEM OF SPEED.*

By M. J. A. NORMAND.

OUR eminent President, M. de Bussy, has invited me to give you some particulars of the Forban. It has seemed to me that I cannot better comply with this invitation than by examining from a general point of view the speed of torpedo vessels. The Forban represents the last step in the march of progress. We shall best understand the laws governing advance in speed by looking back upon the road which has been traversed. The figures which I shall quote will all be taken from torpedo boats of my own construction, because concerning them alone have I exact information, but I acknowledge that extremely remarkable results have been achieved by other builders.

It is chiefly in small vessels up to 200 or 300 tons displacement that progress has been manifested, and the reason is that in them the phenomenon of resistance presents a very special character not observable in vessels of larger displacement.

This character consists in a rising of the vessel due to the vertical component of the direct resistance, as I explained at our last session.

Let D = displacement in tons.

Let V = speed in knots.

The direct resistance is proportional to $D^{\frac{2}{3}} V^2$, and the phenomenon of lifting occurs when the ratio of direct resistance to displacement $\frac{D^{\frac{2}{3}} V^2}{D}$ or $\frac{V^2}{D^{\frac{1}{3}}}$, attains a certain value. In a torpedo boat of 125 tons, this is at a speed of about 20 knots, which corresponds to the speed at which the propulsive efficiency reaches its lowest point; above this speed it improves.

Calling V_1 the speed at which propulsive efficiency is a minimum, $\frac{V_1^2}{D^{\frac{1}{3}}} = \frac{400}{5} = 80$. The worst speed is consequently given by the formula

(1) $V_1 = 9\sqrt{D^{\frac{1}{3}}}$. Thus for a vessel of 300 tons $V_1 = 9\sqrt{6 \cdot 695} = 23 \cdot 3$ knots, and for one of 8000 tons $V_1 = 9\sqrt{20} = 40$ knots. We shall probably not live to see the formula verified for vessels of 8000 tons. These figures are approximate, and

---

* A paper read before the Maritime Technical Association, 1895.

should be corrected for variation of resistance with absolute size, but the law appears to be correct.

The principal lesson taught by the Forban is that the performance of such a vessel improves gradually from 20 to 31 knots. It might have been feared that the slight improvement in performance observed at the highest speeds of all torpedo boats would change sign at still higher speeds, but this does not prove to be the case. What has been already said will explain why the greatest progress has been made in small vessels. This progress is considerable. Eighteen years ago the highest speed attained was 18 or 19 knots; in 1889 it reached with difficulty 21 knots; in 1892 it rose rapidly to 24 knots in an 80-ton torpedo boat and to 25½ knots in 120-ton boats. Then after having slightly exceeded 27 knots in the Chevalier, it has reached to-day more than 29 knots in the Boxer, 30 knots in the Sokol, and 31 knots in the Forban.

It must not be supposed that the speed has increased some 60 per cent. in this space of time, other things remaining equal. The figures given above do not represent the curve of progress realised, they require to be corrected for difference of absolute size and of load carried on trial. I shall try and deduce the real law for this curve. Few studies are so interesting, and the value of this is far from being confined to torpedo vessels, and the law once found can be applied to vessels of the largest size.

Let V = maximum speed in knots.
F = I.H.P.
D = displacement in tons.
a = the fraction of displacement devoted to propelling machinery, which does not include spare gear or reserve water, the importance of which is arbitrary.
π = the weight per indicated horse-power at full power.
M_D = the corresponding coefficient of performance.

Then

$$(2) \quad V = M_D \sqrt[3]{\frac{F}{D^{\frac{2}{3}}}},$$

and $\pi F = a D$ or $F = \frac{a}{\pi} D$.

This value of F substituted in equation (2) gives

$$(3) \quad V = M_D \sqrt[3]{\frac{a}{\pi} D^{\frac{1}{3}}}.$$

The formula (3) is as general as (2), and can be applied in the same way to ships of all descriptions. The slight change in form, as compared with (2), brings out the causes of progress more clearly. Thus it shows that maximum speed depends (1) on proportional efficiency; (2) on the fraction of displacement devoted to propelling power; (3) on the weight per indicated horse-power of propelling power; (4) on displacement.

We will examine separately the influence of the different factors. It will be seen from the table of results of different types of torpedo boats which I have built since 1886 that the propulsive efficiency has not improved, it would even appear to have diminished, but that is probably apparent only. In the Balny the length was twelve times the beam, while in more recent types it is between nine and nine and a-half beams. The propulsive efficiency in proportion to the displacement is less, but the hull has become, if not lighter, at any rate stronger, and the sea-going qualities have been improved. A notably better performance can be obtained by getting rid of the deadwood of the stern, as has been done in most of the English torpedo boats, but the effect is to render them unsteady on a course which may even prove dangerous when steaming in company and in bad weather.

At any rate, it must be admitted that no sensible reduction in propelling efficiency due to absolute size is apparent between displacements of 50 and 200 tons. The advantage which results from increase of displacement depends greatly upon the arbitrary conditions of the problem. If we suppose as I did in 1885, in my "Etude sur les Torpilleurs," that the crew, and all the weights appertaining to the crew, as well as provisions and water, increase only as the square of the lineal dimensions, and that the weights of artillery, torpedoes, and electric light remain constant, then the improvement is considerable; but in practice this is not so, because these weights vary much more often as the cube. When dimensions are increased it is for the purpose of obtaining a greater radius of action, and of rendering the vessel more habitable and able to remain for longer periods at sea. It would not be far from the truth to suppose that by increasing the dimensions only, other things remaining equal, the ratio of all the weights to the displacement will vary but little.

The values of M_D, a and π in the formula (3) being constant, the speed will then vary as $D^{\frac{1}{9}}$. Now if the displacement of a 20-knot torpedo boat be doubled, the speed becomes $20 \times \sqrt[3]{\sqrt[3]{2}} = 21{\cdot}6$. Therefore it is neither to a better performance, or to augmented displacement, that the great progress of recent years must be attributed. It is due to variations of the ratio $\frac{a}{\pi}$ the cube root of which is one of the coefficients of speed, variations which depend upon those of the portion a of the displacement appertaining to the propelling machinery, and above all to the weight per horse-power of propelling machinery π. This weight, which was 72·7 lb. in 1889 in the Avant-garde, is only 35·3 lb. in the Forban—that is, a reduction of one-half in six years. It may be seen by examining the formula (3) that this reduction alone increases the speed in the ratio $\sqrt[3]{2} = 1{\cdot}26$, or from 20 to 25·2 knots.

The increase really amounts to nearly 6 knots when account is taken of the improvement in performance which takes place at extreme speeds. It is due to this, and also to the fact that nearly 20 per cent. more of the displacement has been given to the propelling machinery, that such exceptional results have been obtained in the Forban. It must be admitted that it has been necessary to sacrifice weights, which, if not indispensable, were at least useful; but it does not appear that more sacrifices of this nature have been made in the Forban than in recent British destroyers. As I explained in this place last year, the weight per indicated horse-power of propelling machinery varies with the size. It is high in engines of low power, on account of the exaggerated importance of auxiliary machinery and of tools, and also because a certain minimum thickness of working parts is necessary to provide for wear. It seems to reach a minimum value in sea-going torpedo boats and destroyers, but in the latter vessels, which have from 4000 to 6000 indicated horse-power, this result can only be attained at the expense of a very high rate of revolution. Thus the revolutions of the Sokol were 420, while in the Forban they do not exceed 365. As the linear dimensions of the engines and of the vessels increase, and as the service becomes more prolonged and important, the weight per indicated horse-power of both engines and boilers must increase. In torpedo boats and destroyers of from 120 to 300 tons, which are alone dealt with in this paper, it may be assumed that the weight per indicated horse-power is independent of size. It will in that case depend only, other things being equal, upon the economy of engines and boilers and upon the type of boilers. The same observation is applicable to the hull, and within the same limits of displacement, the proportion borne by the weight of hull to the cube of the linear dimensions is fairly constant. Above about 300 tons the ratio of the weight of hull must be increased if it is desired that a given stress upon the material be not exceeded.

I first introduced feed heaters, steam traps, and cylinder relief valves discharging into the steam chests in Nos. 126, 129, and the Avant-Garde, and although the engines were double-expansion only, the saving of steam was considerable. Later, in the torpedo boats 147 and others, and those of the Lancier type, the pressure was raised, triple-expansion adopted, and water-tube boilers substituted for locomotive. By these means the coal consumption was again reduced, and the total saving in weight of boilers was partly due to the fact that the weight of the water-tube type is only half that of the locomotive, and partly to a further economy in steam consumption. In 1886 the consumption of coal was 2·64 lb. per indicated horse-power at full speed and 2·2 lb. at low speed, and these figures were comparatively low. In consequence of the alterations already described, it has to-day fallen to 1·54 lb. and 1·1 lb. respectively. The reduction is such that, although the radius of action is extended, the actual weight of coal is less, the weight saved being available for machinery. Nothing shows more clearly the truth of the principle too long ignored, that economy tends to lightness. The history of the progress of the torpedo boat is that of the progress of the steam engine.

It only remains for me to examine the possibilities of a further rise in speed. There is no doubt that we are far from having reached the limit. By simply perfecting means already known, by employing stronger materials and higher pressures a considerable advance may be made. We must abandon at least for the present, the employment of light alloys of aluminium for the shell plating of vessels. It is regrettable, because when we consider that the tension on the material of small vessels is very small, and that the minimum thickness of plating is determined by the resistance of the material to compression and by wear, we find that by the use of an alloy of a specific gravity of 2·8, and having tensile strength of 12·7 tons per square inch with 16 per cent. extension, a reduction of about 40 per cent. would be effected in the weight of hull proper, and of about 20 per cent. in the total weight of hull, including fitting, and armament.

But there is another direction in which progress may be made, and to which I wish to call attention. The volume of the above water portion of these small boats amounts to from one and a-half to twice the underwater volume. No doubt some reserve buoyancy is indispensable, since the vessels depend upon water-tight compartments for safety, and it is necessary that they should be navigable and seaworthy with at least one compartment full; but is it necessary to have so large a reserve as that now adopted? It would not be if there were a raised platform deck upon which the work of the ship could be done, and under which the sea could freely pass. Between the submarine vessel in which there is no reserve buoyancy, and the present type in which there is much more than is required for the safety of the ship, there lies a mean, the adoption of which would probably admit of a large reduction in the weight of hull, which now amounts to more than one-third of the whole displacement, and the weight saved could be added to propelling machinery. It is possible for a Whitehead torpedo to attain a speed of 30 knots, because the total immersion affords sufficient displacement to enable a powerful motor to be carried. Although the Forban is probably too small to be fitted with a raised deck, let us see, if only to fix our ideas, and without troubling to consider the necessary change of form and proportions, what would be gained in this little vessel if she were immersed as deeply as would become possible if she were so provided. Suppose the displacement increased in the proportion of two to three, that is from 126·8 to 190·2 tons. This is not an unreasonable assumption since the volume of the above-water portion of the hull is now as much as 1¾ times the displacement in trial condition. The additional displacement, amounting to 63·4 tons, would be disposed of as follows:—

	Tons.
For flying deck	4·00
For extra coal to give the same radius of action (the consumption per mile would vary as $D^{\frac{2}{3}}$	2·50
For strengthening of hull to suit extra power ..	2·50
	9·00

The remaining weight available for increasing power would be 54·4 tons, and the total weight of machinery would become 118 tons. The value of a would be $\frac{118{\cdot}08}{190{\cdot}21} = {\cdot}621$. If the weight per I.H.P. and the efficiency remained unchanged the speed would become $V = 5{\cdot}74 \sqrt[3]{\frac{0{\cdot}621}{0{\cdot}0159} \times \sqrt[3]{190{\cdot}21}}$ $= 34{\cdot}9$ knots, or 4 knots more than at present. The propulsive coefficient of the vessel would probably not be reduced. The worst speed would be about $V_1 = 9\sqrt[3]{\sqrt[3]{190{\cdot}2}} = 21{\cdot}6$ knots, or 13·3 knots below the maximum, instead of 11 knots below it as in the Forban, and the effect of the lifting action would be very considerable. I must admit that so large an increase of speed is not possible in the Forban unless very great modifications are made in the design of the machinery, which now occupies so much space in the vessel that it cannot well be enlarged.

The same is not true of larger vessels, and it seems probable that several additional knots could be obtained in this way if the steam pressure were considerably raised and the cylinder volume reduced. The use of petroleum fuel would greatly facilitate the solution of the problem, because the length of the grates has already attained a maximum with coal, and the power of the boilers is now limited by the width of grate that the beam of the vessel will accommodate.

This is not the place to examine whether excessive speed has really the importance generally attributed to it, but if the flying deck is ever adopted it will probably be for other reasons—an extended radius of action, for example. The space between the flying deck and the top of the vessel would be used for storing a reserve of coal in bags. This would form an excellent protection to the machinery, and would be safer than internal coal protection where water-tube boilers are employed. In case of bad weather, or of circumstances requiring the attainment of the highest possible speed, the vessel could be rapidly lightened.

The form of the transverse sections would be such as to secure stability with coal so stowed, and in this manner a greater amount of consumable stores could be carried in a vessel of given size than would be otherwise possible, unless she were provided with water ballast, and the guns and torpedo tubes could be carried as high above the water as in a vessel of three times the displacement. Sixteen years ago I proposed to fit a flying deck in the case of torpedo boat No. 60, and the proposal was accepted on condition that the stability was augmented; but the increase of beam required to effect this would have prevented the attainment of the desired speed, and the project was abandoned. Since then the principle has been successfully applied in American "whalebacks."

These are, if I am not mistaken, the causes of recent progress, and some of those which may lead to further advances in the speed of small vessels. The principles are very simple, but their application is difficult.

In conclusion, I must apologise for having written at such length about vessels of apparently such little interest as torpedo boats, but size is not a sure test of importance. A celebrated foreign engineer has said that no other class of ship has contributed so much to the progress of naval construction. Nothing is more true, and in addition to the light which torpedo boats have thrown on the theories of resistance and of propulsion, they have taught most valuable lessons on steam engine design. Improvements applicable in small vessels are equally so in large, and there is no reason why the most powerful machinery should require more than 11 lb. of steam per indicated horse-power, and the weight of boilers could be reduced to a fraction of what it is to-day. When these results are achieved, let the tiny vessels which have led the way not be forgotten.

Torpedo Boats.

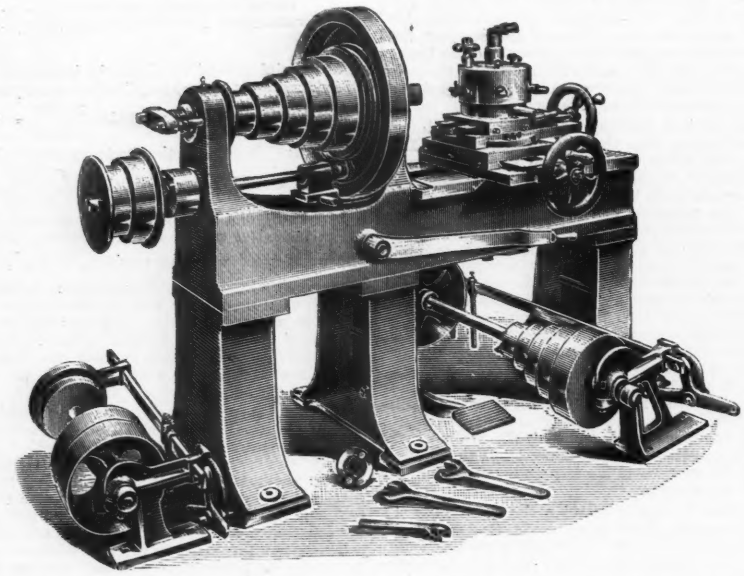
BRASS FINISHERS' LATHE

MESSRS. CARTER AND WRIGHT, ENGINEERS, HALIFAX.



BRASS FINISHERS' AND CYCLE MANUFACTURERS' CAPSTAN LATHE.

This lathe, in addition to the ordinary arrangement of a capstan lathe for turning, boring, and facing, possesses a very simple, powerful, effective, and sensitive arrangement for screwing and tapping, whereby a valve or any other class of work to be operated upon can be turned, bored, and faced by the ordinary driving belt, which operates directly on the spindle cone, and then tapped or screwed by an increased power obtained by a large driving disc mounted on the cone spindle, the disc having internal grooves cut therein to admit a small driving pulley. The latter is mounted on a shaft with oscillating bearings, and receives its motion from a separate cone and overhead motion. When tapping or screwing, the lever in front of the lathe bed is raised, thereby pressing the periphery of the small driving pulley within the outer groove of the disc, and the tap or die, which is held in a steel rack socket in the capstan rest, is forced into the work by a rack pinion on the rest, and as soon as the required length is screwed or tapped, the lever in front of the bed is released and the foot applied to a brake—in a convenient position for the workmen—which acts directly on the periphery of the disc, thereby stopping the rotation of the spindle. The lever is then depressed, and the small friction pulley runs the disc in the opposite direction at an increased speed. For cycle work the fast head spindle is hollow, and a universal chuck and a cutting-off rest with two tool posts are fitted to the bed. When for ordinary brass work, a two-jaw universal chuck without a cutting-off rest is used, but for valves a universal chuck with rotary jaws, so that a valve can be finished at one setting, is provided. With a chuck of the latter construction a youth can bore, face, chase, and seat the body of an inch valve in two minutes.

The above illustration is from a 9in. lathe with six tool-holders, and sufficiently represents its construction without further description. The lathes are made in three sizes—7in., 9in., and 12in. centres, by Messrs. Carter and Wright, Hexagon, Ironworks Halifax.

THE CARDIFF EXHIBITION.

Now that the Cardiff Exhibition has been made more ship-shape, and is in all but the engineering department practically complete, it is possible to form a better opinion of its merits, and the result of further inspection confirms the favourable view expressed in The Engineer on May 8th. The buildings are seen to be admirably contrived for their purpose, as well they might be, since Mr. E. Seward, the architect, has made a special study of exhibition requirements at home and on the Continent. They afford ample space, abundant light, and are at the same time sufficiently compact. The structure is in every way worthy of the site which, though in the centre of the town, affords a delightful combination of meadow, grove, and garden. The variety of the attractions is exceptionally large, and, while popular tastes are duly regarded, the distinctive note of the undertaking is undoubtedly to be found in the suggestive or educational value of the objects gathered together in the mining, maritime, and engineering sections. It was to be expected that in the largest coal port in the world, as Cardiff claims to be, the colliery and shipping industries would be well represented. These departments are, in fact, the most prominent and comprehensive in the Exhibition, that portion of the building set aside for the mining exhibits presenting a series of object lessons as interesting to the engineer as they should be useful to the engineering student. In the grounds close by there has been erected a model of a coal mine in operation, which is a striking piece of realism, and does credit to the ingenuity of Mr. Gascoyne Dalziel, M.E., and the mining engineers who assisted him in its construction. Something of the kind has been done before at Newcastle, but nothing on so large a scale or so elaborate in detail. The visitor passes through swing doors to find himself at the bottom of the downcast shaft of a modern steam-coal pit, with the engine plane stretching into the darkness beyond. He is supplied with a safety lamp, and discovers duplicate roadways leading to the workings, laid with rails, and provided with trams, hauled on one track by steam power and on the other by electricity. Blocks of coal from the steam collieries of the district are piled high to form the walls and face, in such a manner as to show how the seams lie *in situ*; and here an electric coal cutter—Atkinson and Goolden's patent—is at work. The roof and sides are timbered with a prodigal disregard of material, which would vex the heart of some parsimonious colliery managers, and it is really a perfect piece of work of its kind, performed by Mr. Jenkins, of the Cymmer Colliery, who is said to be the most expert timberman in South Wales. The processes of pumping are illustrated by an electric pump, capable of discharging 8000 gallons an hour against a head of 500ft. There are intake and return airways, supplied by one of Waddle's fans, which drives 50,000 cubic feet of air a minute through the workings. Barometer, thermometer, anemometer, all are in their proper places, and in addition there is a Shaw's gas-testing apparatus, which, according to the patentee, will detect and register so infinitesimal a trace as 0·1 per cent. of foul air in the ventilating current. Everything here—trams, rails, &c.—was in actual use in pits in the Rhondda Valley or Monmouthshire a month or so ago, and the height and width of the roadways are those of an ordinary steam-coal colliery.

Near at hand is a separate exhibition of coal as it is won from the mine, or rather as it can be won by special effort. To exemplify the hardness of certain seams, Glamorganshire and Monmouthshire coalowners would seem to have entered into a friendly competition for the production of the largest block. The palm must be given to the enormous mass shown by Powell's Tillery Company from the well-known Monmouthshire black vein; it weighs about five and a-half tons, and was hewn some three-quarters of a mile from the bottom of the shaft. Only a trifle smaller is the specimen of the Patent Nut and Bolt Company, Cwmbran, 10ft. 6in. long, 3ft. 9½in. in height, 3ft. 3in. wide, and weighing about four tons. The Dowlais Company sends similar examples from its new colliery at Aberdare Junction, which is sunk to a depth of 740 yards, and is the deepest pit in the coalfield. These are the more conspicuous of the exhibits of coal; but we must not omit to mention the United National Company's section, about 10ft. high, showing the run of the veins in the Risca Colliery, with the intervening and supervening shale and rubbish. A pumping engine in motion, from Messrs. Bever and Dorling, Dewsbury; a horizontal air compressor, supplying air at 80 lb. pressure to a 1in. Reidler pump, from Messrs. Fraser and Chalmers, Threadneedle-street; a case of all sorts of explosives, in *fac simile*, from Nobel's Company; and safety lamps in any number from various makers, including the first Davy ever used underground, are all worth notice. So, too, is the model from Messrs. Robey, of Lincoln, of a ten-head stamp battery, comparatively light in structure, with its strength concentrated in those parts subjected to the greatest working stress. The heads, which can be worked in sections of five, if needful, are made in one solid forging of steel, and are said to be unbreakable; while it is claimed as a feature of the battery that all the working parts are accessible, with large spaces between them, so that there is room to take out parts for renewal, and give the millman a full view of the front plates and easy access to the mortar box.

The South Kensington Museum lends a valuable collection of models, most of which have been seen elsewhere, though several no doubt derive a special interest from their present surroundings. Three, for instance, illustrate several methods of timbering levels, as well as what is called "overhand and underhand working," in a Freiberg mine. Another shows the tubbing and guides used in La Grange shaft at Guzin, France. A Japanese model exhibits a section of a gold and silver mine at Aoban, Sado Island. There are, besides, several cabinets of mineralogical specimens, that from the Imperial Institute embracing the native ores of India, Canada, New South Wales, and South Africa, in connection therewith being examples of quartz, &c., from the Rand and Matabeleland, lent by the De Beers Company, which also sends a sectional model of the Kimberley mine. One of the most valuable contributions to this section is made by the South Wales and Monmouthshire Coalowners' Association, whose secretary, Mr. Gascoyne Dalziel, has been for some months engaged in gathering the material. It consists, in one form, of a picture of the South Wales coalfield, and, in another, of a history of the trade. Mr. Forster Brown and Mr. Theodore Vachell have assisted Mr. Dalziel to prepare a vertical section of all the coal seams proved in East Glamorganshire and Monmouthshire, and this is further illustrated by samples of each vein of coal, labelled and numbered to correspond with the chart. The thickness of the steam coals in the Aberdare Valley is shown in a supplementary section by Mr. Thomas Evans, M.E., while another drawing represents the strata penetrated in sinking the Harris' Navigation Colliery, the deepest in South Wales until the neighbouring Dowlais pit was opened. Tables and diagrams, the outcome of Mr. Dalziel's laborious effort, show the actual selling prices of South Wales coal f.o.b., from 1845 to 1895, and the fluctuations in miners' wages in the district from 1875 to 1896, which is practically the period in which wages have been regulated by the sliding scale agreement. Plans of Cardiff, Penarth, and Barry Docks, and of Newport and Swansea Docks are at hand to enlighten the stranger from afar as to the accommodation provided for coal shipments, and lest it should be thought that this is ample, it may be well to remark that on every hand new docks or dock extensions are even now being made.

Other exhibitions, especially the Naval Exhibition, will no doubt have familiarised a good many visitors with the principal maritime objects collected together from all parts of the country. It is nevertheless an interesting and instructive department, and probably the most extensive of all. At a glance one perceives that the chief contributors are Messrs. Armstrong, Mitchell, and Co.; Messrs. Laird, of Birkenhead; and Lloyd's Register of British and Foreign Shipping, who divide between them most of the 8400 square feet of space. Most of the models and other exhibits from the three sources have been described in these columns in other connections, and considerations of space compel us now merely to refer to them *en bloc*, while we pass on to other features. Models of harbours and docks are present in number and variety, from the large-scale plan in relief—132ft. to 1in.—of the Tyne, with its jutting piers and populous banks, to the extensive but more highly-finished model of Southampton Harbour, showing the existing docks, the new works in progress and those in contemplation—a truly graphic example of what a model ought to be—on a scale of 50ft. to 1in., and exposing an area of 1090 acres, of which the dock and quay basins occupy 360 acres. This fine work was designed and constructed by Messrs. J. P. Jordan and J. P. Maginnis. It is, of course, a loan from the South-Western Railway Company, which sends also models of its twin-screw steamers Columbia and Alma, of the Southampton and Havre service. From the Mersey Dock and Harbour Board come models of the Mersey from the bar to Warrington, and of the approaches to the landing-stage. Sunderland is represented on a scale of 40ft. to 1in., with the new piers in course of construction; and the River Wear Commissioners contribute likewise models of a radial crane for setting concrete blocks of 52 tons weight; of the sand pump suction dredger Sandhill; of Wake's steam concrete bag barge, constructed to deposit concrete bags 56 tons and 115 tons in weight for the foundations of the new piers; and of a dredger and hopper barge, capable of lifting about 600 tons per hour. The Floating Pontoon Dock at Avonmouth, and Barry Docks are the subjects of other models. The 900-ton gates of Barry Dock are represented in model by the Thames Ironworks and Shipbuilding Company, and so are the Chatham and Dover bridge at Blackfriars, Woolwich Ferry, the Blackwall Tunnel, and the Royal Albert Docks, from the same company's works. A general model of the East India Docks is lent by the London and India Docks Joint Committee, which sends an interesting reproduction of the automatic tipping lift designed by Mr. H. F. Donaldson, M.I.C.E., and capable of lifting thirty sheep a distance of 50ft. in one minute.

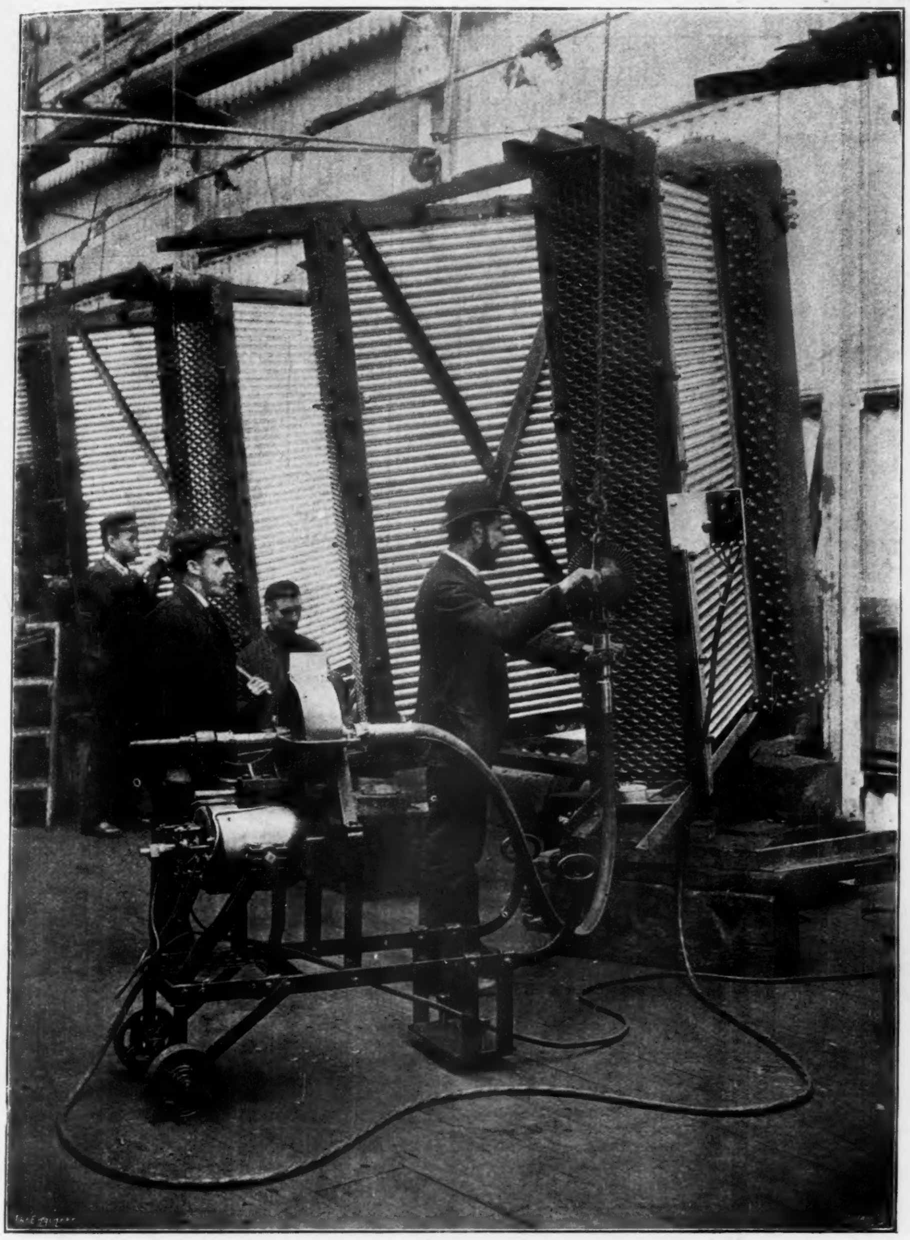
The telegraph steamship Faraday, at once identified by her two funnels abreast, to allow of the cable being paid out amidships; fine examples of the fleets of Donald Currie and Co., the Union Steamship Company, and the American Transatlantic Line; and models of some of the best productions of the Clyde builders have their place here. Noteworthy exhibits of water-tube boilers, machinery, and all kinds of shipping appliances represent the North-Eastern Marine Engineering Company, Wallsend; T. L. Thompson and Sons, North Shields; the Darlington Forge Company; William Doxford and Son, Sunderland, including models of the latest type of torpedo destroyers; John Brown and Co., Sheffield; and a number of other eminent firms.

TRACTION ENGINES ON ROADS.

The House of Commons Committee sat for the last time to hear evidence on the above subject, on Thursday, the 14th inst. The only witness on that day was Mr. C. Mulvany, M. Inst. C.E., County Surveyor of Roscommon, Ireland, who has the supervision of 1200 miles of road, the upkeep of which costs between £5 and £16 in the country districts per mile per annum, while the main roads involve an expenditure of £30 per mile for a similar period. In the towns the expenditure is greater, and varies between £80 and £100. Although he had no material evidence of the employment of traction engines in Roscommon, the witness informed the Committee that he had had an opportunity of inspecting their operation in Tyrone, where, with the use of a 14-ton engine, no serious damage was done, but he thought the trucks, which were sometimes overloaded, did considerable damage to the roads. Mr. Mulvany stated that they had no bye-laws in the West of Ireland, nor had the local authorities the power to make them. With the further extension of the employment of this kind of traffic on the public roads, he thought that the weight of engines ought to be restricted to 10 tons, and that the trucks should be constructed so that the wheels broke gauge, under which circumstances the roads would be benefitted rather than injured when they had been raised to a standard suitable for the traffic. He considered that an annual licence fee of £10 for the whole of Ireland would be a reasonable one, but that the owners of engines should still be liable for extraordinary traffic, and thought that the maximum limit of speed on country roads might be increased to six miles per hour. With regard to the third man employed, the witness considered that it should not be necessary for this person to precede the engine. We understand that the Committee will not sit again until June 8th.

King's College Engineering Society.—At the meeting of this Society on the 15th inst., the President opened a debate on "Horse Haulage *versus* Motor Traction," by referring to some of the points for discussion in his paper of May 8th. Mr. Bailey followed, taking the side of horse haulage. He did not attempt to oppose the car for long distance work, but based his arguments in favour of the horse on short trips and canal work. Mr. Standen then rose for the opposition. Referring to many interesting points, he said the motor would make a great difference to the railways. Mr. Hogarth then seconded Mr. Bailey, giving many valuable remarks as to cost and maintenance of a horse, coupled with many arguments against motors. Mr. Tolmé, in seconding Mr. Standen, compared the endurances of horses *versus* motors, much to the advantage of the latter. He also pointed out how useful motors had become in crossing the deserts in Algeria. Mr. Carter and Mr. Simpson joined in the discussion which followed, dealing with characters and efficiencies of motors. Mr. Mowat brought the debate to a close with a few remarks bearing on each side. The division resulted in a majority of two in favour of motors.

EXPANDING TUBES IN YARROW BOILERS



ARMOURED TORPEDO BOAT DESTROYERS FOR THE ARGENTINE GOVERNMENT.

In previous issues—March 13th and 27th ult.—we noted as under construction at the shipyard and works of Messrs. Yarrow and Co., of Poplar, for the Argentine Government, four new torpedo boat destroyers of a type which is a modification of the Sokol, a vessel of the destroyer class built by the same firm for the Russian Government.

In the issue of the later date we fully described one of these vessels, and showed the points of difference between it and its prototype. The principal of these were, it will be remembered, that both the sides and deck—for the length of the machinery and boiler space—were armour plated, and the shape of the hull above water so far modified that all "tumbling home" of the sides is done away with, thus allowing the deck to be the full width of the ship, and the bows made with a considerable flare in order to throw off the seas when going against them, and keep the decks drier.

In previous destroyers, the side plating above water has only been of normal thickness throughout the length of the vessel; but it being recognised that the protection of the vitals of a warship—her propelling machinery, boilers, &c.—is of far greater importance than a slight reduction in her speed, these vessels have been given such a thickness of armour-plating for the part of their sides referred to, as will be proof against the small class of projectiles.

Last Saturday afternoon, the first of the four vessels abovementioned, which has been completed to the launching condition, was put into the water with her machinery and boilers on board, from Messrs. Yarrow's yard with complete success, in the presence of a number of naval and engineering experts.

The boilers for supplying the engines of these vessels with steam are, as we have previously stated, six in number, of Messrs. Yarrow's special water-tube type, each being capable of developing a minimum of 700-horse power. A feature of novelty in their construction worth noting is the method by which the tubes in them—which are perfectly straight—are expanded at their ends, or made to fit the tube plates absolutely steam and water-tight. This is ordinarily effected by means of a percussion expander worked by hand, the mandril being driven up by blows from a hand hammer. The work is not only tedious but laborious, resulting in the expanding of about seventy tubes in a working day.

To accelerate the rate of progress of this work, and to minimise the physical labour attending it, Messrs. Yarrow have brought out a special expander, the body of which is made to revolve, leaving the mandril free to feed itself, thus disposing of the necessity for the use of the hammer during the process of expanding the tube end. The necessary motion is given to the expander by electricity or steam, the motor in the former case being one of those made by Mr. Kodolitsch, of Trieste, which conforms to all the requirements for this class of work; and in using steam the driving power is obtained from ordinary shafting by rope gearing. It is found that the new expander ensures a uniformity of work which cannot be obtained by hand, and that the rate of getting through it is increased from seventy tubes a day per man to thirty tubes per hour.

On the occasion of the launch of the destroyer above referred to—which, by-the-bye, was not named—the experts and other visitors who witnessed it were afforded an opportunity of inspecting a large stern-wheel steamer building by the Messrs. Yarrow—her construction being nearly completed—for the Russian Government for the use of the Trans-Siberian Railway, a work of great magnitude, now being rapidly proceeded with, and to be completed in the year 1900.

This vessel is 120ft. long and 24ft. beam, and in her loaded condition will draw 12in. of water. Her stern wheel is driven by a pair of horizontal engines, placed directly aft—one on either side—of 150 indicated horse-power, supplied with steam from a boiler of the locomotive type, located forward, and she is to have a running speed of twelve miles an hour. The vessel, whose engines and stern wheel were in motion, as she lay on the stocks on which she has been built, will shortly be taken to pieces and shipped to the port of Vladivostock, the eastern extremity of the Trans-Siberian Railway, and from thence transported to the interior of Siberia, and there put together. The main deck of this vessel is flush, and upon it the cargo is generally carried, the cabin accommodation provided being on the upper deck.

In addition to the destroyers building for the Argentine Government, Messrs. Yarrow have also on hand for the Chilian Navy six first-class torpedo boats, which will be an improvement on the Viper, built by them for the Austrian Navy, and whose speed trials we lately noticed. These vessels will be 152ft. 6in. long, 15ft. 3in. beam, and will be fitted with triple-expansion engines to indicate about 2000-horse power, and to drive them at a guaranteed speed of 25½ knots an hour. Steam will be supplied by water-tube boilers of the Yarrow type. The boats will have a large range of action, as their bunker capacity is to be 40 tons, and they will be armed with torpedo ejectors and quick-firing guns.

THE ELECTRICITY STATION AT THE EARL'S COURT EXHIBITION.

The Exhibition at Earl's Court this year is an improved edition of the Empire of India Exhibition, which attracted so many visitors last year. The London Exhibitions Company has spared no trouble to produce an interesting spectacle, and there is now a very complete central station where electricity is generated for the whole of the lighting. Our supplement gives a general view of the interior of the station, and it will be seen that, although merely devoted to the service of an exhibition, the plant is of very considerable size, and is, in fact, capable of a larger output than that used in many stations supplying small towns.

It will doubtless be of interest to our readers to have the details of this station. Mr. G. C. Fricker acted as consulting engineer, and Mr. A. W. Money is the resident engineer for the Exhibitions Company. The whole of the plant is installed in one large room. This is, of course, not an ideal plan, as the boilers should be kept quite apart from the engines wherever it is possible to do so, in order to avoid dust and ashes being carried into the bearings of engines and dynamos. It was, however, found impossible to carry out this system in the present instance owing to the limited space at disposal. A canvas screen has, therefore, been drawn across at the back of the stoking floor, and this appears to obviate most of the difficulty. The presence of the whole of the plant in one room has this advantage—that the engineer-in-charge can overlook the whole of the attendants from the elevated gallery which surrounds the switchboard. The board itself is arranged upon three sides of a square tower, not shown in our engraving, and the upper part is surrounded by the gallery alluded to, and is reached by a flight of steps. In order to give a general view of the plant, both the board and the canvas screen have been omitted in our general view, otherwise only a very limited portion of the whole plant could be seen at once.

The station building adjoins the Exhibition theatre, and is close to the Midland Railway siding. Coal is brought within a few yards of the station by truck, and then has to be reloaded into carts and unloaded at the station itself. It seems rather a pity that some arrangement could not have been made whereby the trucks could be brought up to the coal store itself, where the coal could be directly dircharged without using any carts. Ten tons of coal can be stored inside the engine-room itself.

Steam generating plant.—Steam is generated by means of nine boilers of the locomotive type, and of the well-known semi-portable form built by Messrs. Davey, Paxman, and Co., of Colchester. Each boiler is 18ft. 6in. long over all, and has a barrel 4ft. 6in. diameter; the whole of the shell is of mild steel. The fire-box shell is the same width as the barrel, and the internal fire-box is 5ft. 6in. high by 4ft. 6in. long, and has a grate area of 20 square feet; there are 100 iron tubes 2¼in. diameter inside. Steam is collected at the top of a dome, and passes through a steam pipe 3in. diameter to a common receiver, which consists of a mild steel tube 20in. inside diameter, built up in short lengths with flanges welded solid on. At first sight it would appear that some trouble must be found with a long receiver such as this passing across nine boilers, and connected to the separate stop valve of each by a length of about 3ft. of straight pipe; these straight branches, however, enter stuffing-boxes and glands on the receiver, so that there is a certain amount of elasticity which would not be obtained by direct coupling, and we are assured that no trouble has ever been experienced from deterioration of the joints of the stop valves due to expansion and contraction of the receiver. The whole of the boiler fittings are by Messrs. Dewrance and Co., except the injectors, which are by Messrs. Holden and Brooke, of Manchester. Some little difficulty was anticipated owing to the lack of water storage, so a large concrete tank was built in the floor under the barrels of the boilers; this tank is 60ft. long by 5ft. wide by 4ft. deep, and is always kept full of water from the public mains through ball cocks, so that it can give several hours' supply. The makers calculate for an evaporation of at least 9·5 lb. of water per pound of coal from and at 212 deg. Fah., and a consumption of about 19 lb. of coal per square foot of grate per hour. The working pressure is 120 lb. per square inch. Each boiler is provided with a separate vertical wrought iron chimney, 18in. diameter and 30ft. high. Besides the injector supplied to each boiler there are also two of Mumford's steam feed pumps; these feed a common supply pipe connected to each of the clack boxes, so that there is a double feed to each boiler. In ordinary work it is found that one feed pump is sufficient to supply all the feed-water required, although we are told that the boilers steam slightly better when the injectors are used than when the pumps are employed The joints of the steam pipes are made with corrugated brass rings, coated with red lead cement. These rings are made by Messrs. Newton and Nicholson, of Tyne Docks, South Shields.

Engines and dynamos.—Leaving now the steam generating plant, we shall describe the steam and electric plant; the former was all supplied by Messrs. Davey, Paxman, and Co., and the latter by the Brush Electric Company. At one end of the building are three fine sets of Peache's patent high-speed engines, direct-coupled to alternators. We will not now describe the Peache engine in detail, as we dealt with it in our issue of December 6th, 1895, upon page 550, and our readers will doubtless recollect the ingenious arrangement by which the use of excentrics is obviated. The whole of the joints of the rods inside the oil chamber are partly cut away at the top, so as to allow perfectly free access of the lubricant to the wearing surfaces. We carefully examined a number of these joints and could find no trace of wear or scoring, although the engines have now been in use a considerable time. Two of the engines consist, as will be seen, of three compound single-acting tandem sets in parallel, and each engine developes 220 indicated horse-power, and is direct-coupled to a Mordey alternator capable of developing 100 kilowatts, at a speed of 325 revolutions per minute. The other engine consists of two compound single-acting tandem sets in parallel, and the engine developes 150 indicated horse-power and is direct-coupled to a Mordey alternator, which developes 75 kilowatts at a speed of 350 revolutions per minute. The sizes of the cylinders are in all cases the same, 10in. and 15in. by 10in. stroke.

On another page, by the courtesy of the inventor of the engine, Mr. J. C. Peache, we are able to reproduce some indicator diagrams, Fig. 6, taken from one of the six-cylinder engines in ordinary work. Although they fairly represent the distribution of steam in the engines, they only give about three-quarters of the full capacity of the engine. The speed had to be reduced from 400 revolutions per minute to about 325, to suit the Mordey alternator to which it is coupled, and the M.E.P. is also less than is recommended in usual practice. It must always be remembered that the engines at Earl's Court are the first which were built, and in the engines now being built many details have been altered, as, for instance, the arrangement of the governors.

The total power indicated for the three sets of the one engine, as shown by the diagrams, is 171·3 indicated horse-power. The normal indicated horse-power of this size of engine is 260 indicated horse-power.

The frequency of each alternator is 130 alternations per second. All the machines are of the Brush Company's new armoured coil type. Each alternator frame serves as an oil reservoir, and the lubricant is caused to circulate to the bearings by means of a small centrifugal pump.

Passing to the other end of the building, we find the other half of the plant; this consists of three engines. The first is of the Colchester type, horizontal, compound side-by-side engine. The high-pressure cylinder is 12¾in. diameter; the low-pressure 20in. diameter, and the stroke 24in.

SWITCHES AND SWITCH BOARDS AT THE INDIA AND CEYLON EXHIBITION

This engine will develope 140 indicated horse-power with 120 lb. of steam, when running at 100 revolutions per minute; it has a fly-wheel 9ft. diameter, and drives by means of a double leather belt 16in. wide a 75-kilowatt Mordey alternator. The second engine is of the girder type, and has the same size cylinders as the first, but is provided with two fly-wheels, each 8ft. 6in. diameter and 11½in. wide. Each fly-wheel is provided with a double leather belt, 10in. wide. One drives a Brush arc lighter for fifty-five lights, and the other drives a 40-kilowatt direct current compound wound 100-volt Brush machine, used for the lighting of the theatre by means of arc lamps, placed two in series, and also for the charging of accumulators for the electric launches.

The third engine is of the Colchester type, developing 220 indicated horse-power, at 100 revolutions with steam of 120 lb. pressure. The cylinders are compound, the high-pressure being 18¾in. diameter, and the low-pressure 28in. diameter by 24in. stroke. The fly-wheel is 10ft. diameter, and has a double leather belt 2ft. wide driving on to a pulley 4ft. diameter fixed to a countershaft carried upon pedestals placed on the floor. This countershaft is of mild steel, 4½in. diameter, and runs at 250 revolutions per minute. It carries five driving pulleys, four of which each drive by belting a 55-arc light Brush machine series wound; and the fifth drives also by belting a 25-kilowatt Vienna Brush compound wound machine. All the engines are fitted with Messrs. Davey, Paxman, and Co.'s governors, and the high-pressure cylinder is provided with an expansion valve which works at the back of the steam valve proper. This arrangement of valve gear has been fully illustrated in our columns. One excentric drives the main slide valve, while two other excentrics drive the subsidiary valve through a die to a link; the position of the link is controlled by the governor. In Fig. 8 we give indicator diagrams taken from these engines, which clearly show the good distribution obtained with this type of valve gear.

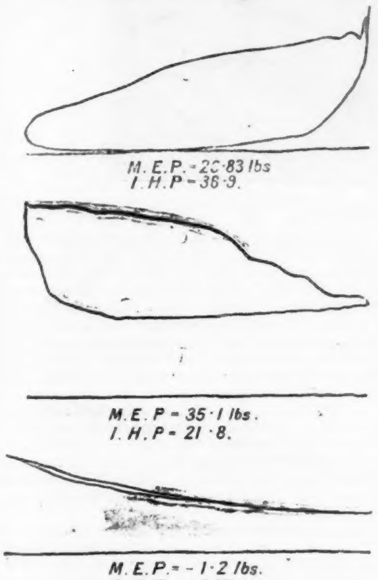

Fig. 6—Indicator Diagrams from the Peache Engines at 310 Revolutions per Minute

Switchboards.—The upper part of the central structure in the centre of the building is occupied by three switchboards. The first consists of four marble panels, one of which we illustrate in Fig. 1. At the bottom is the adjustable resistance in the shunt coils of the exciters for the alternators. At the right side above is a throw-over switch with carbon break; the middle contacts are the terminals of the field of an alternator, the lower terminals are used to short circuit the field on itself when breaking circuit, and the upper terminals are connected with the centre of the left-hand throw-over switch; these two switches are shown diagrammatically in Fig. 2. The left-hand switch has its lower terminals connected to the exciter of the alternator and its upper terminals connected direct to the omnibus bars of the 40-kilowatt or 25-kilowatt direct current machines, so that the alternator can be excited either by its own exciter or by any one of the other direct current machines. Above these switches are fixed the voltmeter and amperèmeter; the voltmeter shows the electro-motive force of one coil, no transformer being used, and the amperèmeter shows the ampères flowing in primary. Above these there is a double-pole trigger switch and double-pole Bates fuses.

An Ayrton and Mather electrostatic gravity voltmeter is used to calibrate the others, and reads up to 2400 volts. Next to this board is the Brush arc light switchboard, with five circuits and connections for six machines. One of the circuits is shown in Fig. 3, and an amperèmeter is provided for each circuit. The board is extremely simple, and the method of hanging on the connector to two gun-metal hooks leaves little to be desired; it seems distinctly preferable to the plug system for a small number of circuits. By means of this board any circuit can be connected to any machine. This is the low tension board for the arc lighting. Adjoining this board is the high tension board for connecting any machine to any feeding circuit; one of the panels is shown in Fig. 4. Sixteen circuits, each consisting of 7/18 cable, leave the station and carry currents 2000 volts potential; each circuit leaves the station through a single-pole switch and double-pole Bates fuses. There are four pairs of omnibus bars behind the board, and by means of plugs it is easy to connect any circuit to any alternator. A diagram of connections is shown in Fig. 4A. On the ground level there is another board which carries a special switch, designed by Mr. Money, and shown diagrammatically in three different positions, 1, 2, and 3 in Fig. 5. It enables the lighting to be effected entirely either by the 40-kilowatt direct current machine, or by the 25-kilowatt direct current machine, or jointly by both.

Each machine is shown connected through double-pole switches to the mains leading to the switch, and each is provided with an amperèmeter A and a voltmeter V. The switch itself consists of a Y-shaped handle with metal arc-shaped contacts. In one of the limbs of the Y there is insulation; outside the handle is a ring with six contacts, the shaded portions representing insulation, and the unshaded portions metal contacts. In Position 1, the 40-kilowatt machine is feeding lamps L, the current passing back through C, the handle, and B to the dynamo. In the same way the 25-kilowatt machine is feeding lamps L¹, and the current passes back through D, the handle, and E to the machine; but the machines are not in parallel. In Position 2, the 40-kilowatt machine is doing the whole of the work and lighting lamps L and L¹, for the current flows from the + terminal to the outside leads through the lamps, and back from the L section to G, and from the L¹ section through D and C also to G, and thence through B to the machine. Position 3 shows the 25-kilowatt machine doing all the work. This switch can be easily manipulated, with scarcely any spark. The currents in the arc light circuits are kept constant by means of Brush-Geipel regulators.

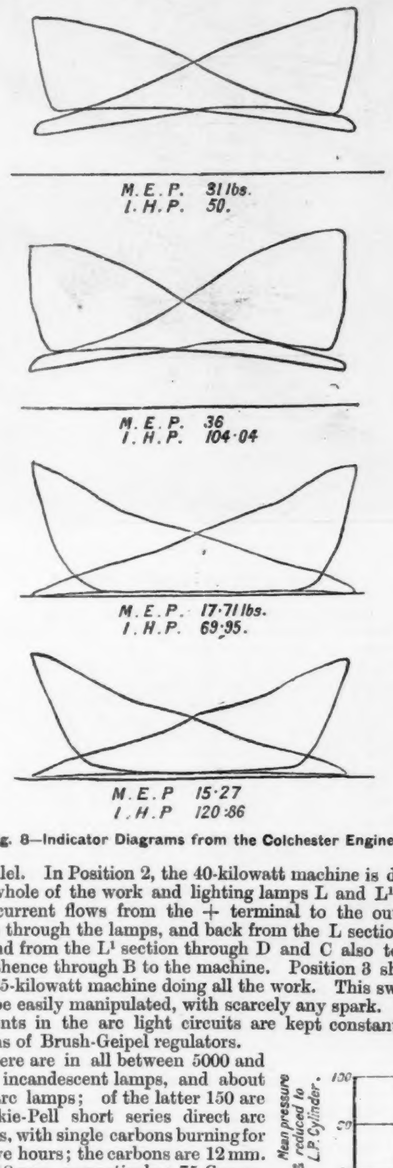

Fig. 8—Indicator Diagrams from the Colchester Engines

There are in all between 5000 and 6000 incandescent lamps, and about 275 arc lamps; of the latter 150 are Brockie-Pell short series direct arc lamps, with single carbons burning for twelve hours; the carbons are 12 mm. and 18 mm. respectively; 75 Crompton Pochin arc lamps are worked direct off the Brush 55-light machines. There are also 32 arc lamps for 15 ampéres, each of a type designed by Messrs. Money and Nash; these are run two in series direct off the 105-volt machines, and have single carbons, and light the auditorium of the theatre; also 36 alternate current arc lamps by Messrs. Siemens Brothers and Co. run in parallel off 50-volt converters. There are transformer sub-stations about the Exhibition grounds, and these are supplied with current through leads run into iron gas barrel 1in. diameter buried in the ground. Messrs. Siemens Brothers and Co. supplied the whole of the cable used in the Exhibition.

Quite recently Prof. Alex. B. W. Kennedy has made very careful trials of a Peache high-speed engine at the works of Messrs. Davey, Paxman and Co., Colchester; but before dealing with the results then obtained, we will say one or two words about the construction of the engines.

As stated earlier in our article, the engines at Earl's Court are, with the exception of an experimental engine, the first of this type which have been built, and differ in the arrangement of the governor from the standard type at present being constructed. All parts of the engines are as readily accessible for examination or removal as in the case of a double-acting engine of the usual construction. The moving parts and their fastenings are strong, and do not call for special knowledge or undue nicety in fixing or adjusting, and there are no internal glands. The steam cylinders are perfectly isolated from the working chamber. No steam or heat can get from the cylinders to the working chamber, and the temperature of the bath of lubricant never rises above 100 deg. Fah., or thereabouts. Consequently the lubricant remains in good and effective condition, and no artificial cooling, such as cold water cooling pipes, or other devices, have to be resorted to. The isolation of the steam cylinders from the working chamber precludes the possibility of oil from the working chamber being drawn up into the condenser if the engines are worked condensing. All bearings are made of ample size, and the engines will readily bear loading up to an M.E.P. of 60 lb. or more per square inch referred to the L.P. piston. We may add that these engines were running through the last season of the Exhibition, and that then, as now, the demands were such as to need all three engines at work at the same time. During the evening they are therefore running without any reserve plant. Although one of the three engines is a two-crank engine, Messrs. Davey, Paxman and Co. have definitely adopted the three-crank type as their standard, to the exclusion of the single or double-crank type.

REPORT ON TEST OF HIGH SPEED ENGINE—PEACHE'S PATENT—AT COLCHESTER ON APRIL 16TH, 1896.

14, Old Queen-street, Westminster,
London, S.W., 11th May, 1896.

Messrs. Davey, Paxman, and Co., Colchester.

Dear Sirs,—I have pleasure in reporting to you the results of trials which I carried out at your works on the 16th ult. upon one of Mr. Peache's high-speed engines. The main objects of the trial were the determinations of the efficiency and the steam consumption of the engine at various loads.

The engine tested was of a new type, specially adapted for high speed running. It was a single crank compound engine, the two cylinders being tandem, and respectively 10in. and 15in. diameter, with a length of stroke of 10⅛in. The exact dimensions were 10·02, 15·00, and 10·11, as found by measurement after the trial, and these dimensions have been taken into account in the calculations.

The engine was intended to work at about 80 indicated horse-power, and at about 375 revolutions per minute. The work done was taken up by a brake wheel, having a channel-shaped rim cooled by water. The brake wheel was encircled by eight ropes each about 1½in. diameter, the weight of the ropes on the two sides being carefully balanced. The brake was loaded with dead weights on one side, and the back pull taken up by a spring balance.

The engine was non-condensing. It was therefore necessary to determine the weight of steam used by weighing the water as it went into the boiler. This was done by a special arrangement erected for the purpose, in which the measuring tank was placed on the platform of a weighing machine, which was afterwards checked with dead weights. The water was passed through this tank, 2 cwt. at a time. The feed pump used during the trial was supplied with steam from a separate boiler. The whole of the feed and steam pipes—the latter being temporarily covered with non-conducting material—were visible, and all the connections were checked.

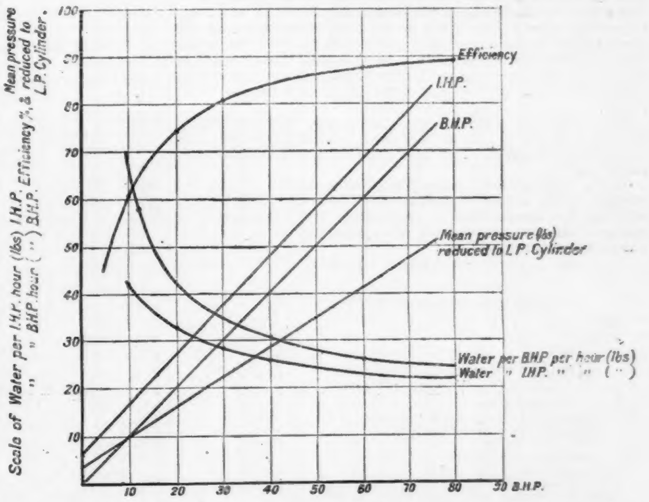
The boiler used was a locomotive boiler. The water level was kept low in the gauge glass, but in spite of this the steam blown off from the indicator cocks on the engine looked by no means very dry, and I am afraid that the steam consumption may on this ground have been somewhat larger than if the steam had been entirely free from moisture. No allowance, however, has been made on this account, as the quantity of wetness in the steam was not measured.

I had the whole of the apparatus to be used on the trial tested beforehand, and a rehearsal of the trial was run on the 15th April, to make sure that everything was in working order. The actual trials I carried out on the 16th April.

A full power run was carried out over about five hours, the results of this trial being the most important. At three-quarter load, half load, and quarter load, the trials lasted about one hour each, the exact times being stated in every case in the annexed table. The engine worked exceedingly well, indeed without the slightest hitch or difficulty of any kind, during the whole of the day, and after the trial was over I found the bath of lubricant to be quite cool, although the engine had been running continuously for very nearly twelve hours. The principal results are shown in the table appended to this report, and also in the diagrams, of which copies are enclosed.

It is necessary to make the following remarks as to the indicated horse-power. The indicator cards were worked out by a planimeter in the usual way, and the high-pressure cards reduced to the area of the low-pressure piston. Indicator diagrams taken from the valve chamber, which were found to be positive, were worked out, and the mean-pressure taken for each power and then reduced to the corresponding pressure on the low-pressure cylinder. Indicator diagrams were also taken from the controller at each power. These cards were found to be negative, and the corresponding mean-pressure was deducted from the effective mean-pressure on the low-pressure piston. The differences due to the addition of the valve power and the subtraction of the controller power were very small, but I think it right to take them into account.

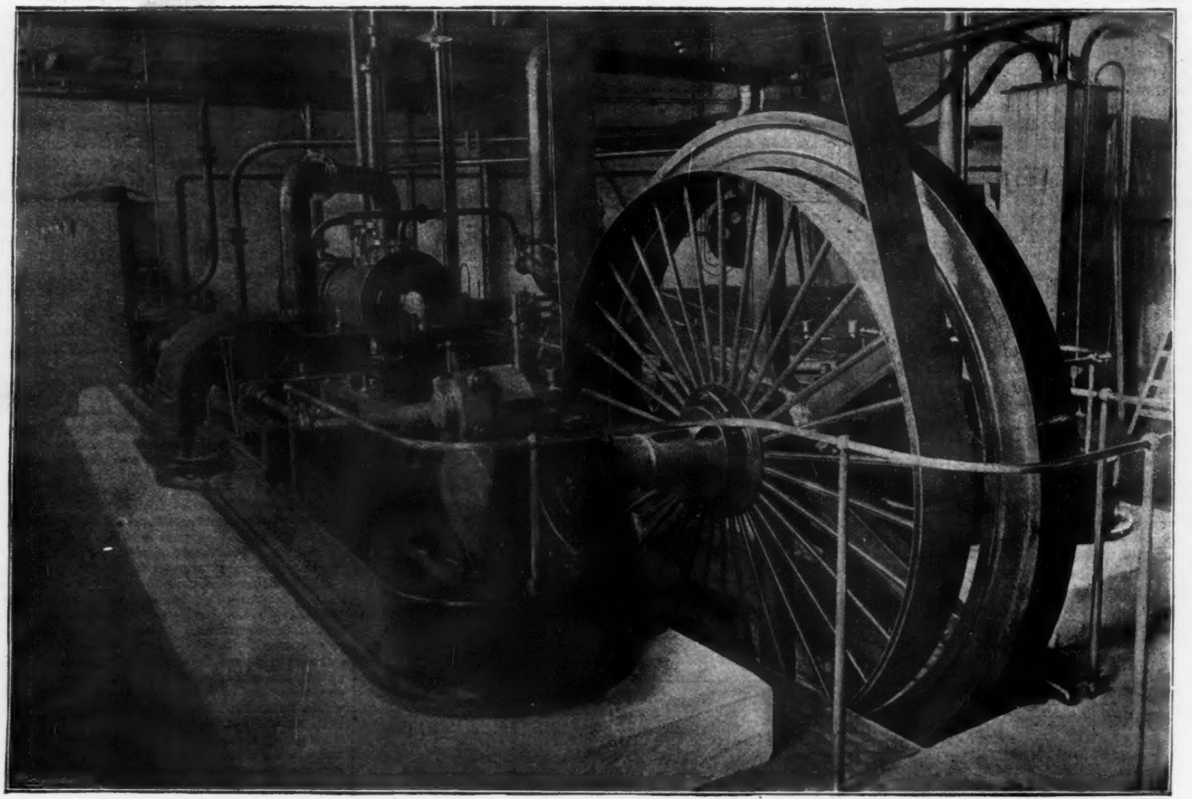
The brake horse-power was found from the brake weights and



AMMONIA ICE-MAKING PLANT—ENGINES AND PUMPS

(*For description see page* 517)

Fig. 1



speed in the usual manner, the whole of the dimensions being carefully measured and the weights checked, and an addition was made for the power necessary to drive the brake itself. This was necessary, as the brake was a very heavy one and had two bearings of its own. Separate trials showed that at 386 revolutions the power necessary to drive the brake wheel empty was 1·8-H.P., and a corresponding allowance has been made in each case.

In the diagram on preceding page are shown the principal results as to efficiency and economy. The dots show the exact observations made; the lines, straight and curved, are drawn so as to correspond as closely as possible to the whole of the observations. The base of the diagram represents brake horse-power, and the lines upon it show the mean pressure—reduced to low-pressure cylinder—the indicated horse-power and the efficiency, the total water per hour, and the water per brake horse-power hour and per indicated horse-power hour. As to these last figures, it will be seen that the very satisfactory result is attained of 22·5 lb. of feed-water, measured into the boiler, per indicated horse-power per hour, and 25·2 lb. of feed-water similarly measured per brake horse-power per hour. The mechanical efficiency at full load, or ratio, of brake horse-power to indicated horse-power was 89·2 per cent. It is a matter of common knowledge that figures of this kind, especially for a small engine, and where it had been impossible to make sure that the steam was thoroughly dry, are extremely good. It is satisfactory to notice also that the rate of increase of water consumption per horse-power hour as the horse-power diminishes is not unduly rapid. This is shown both by the diagram and table.

Diagram No. 719* is practically a plotting of the log sheet of the trials upon a time base. It may be noticed that the full power trial lasted actually about six hours, although the effective running time was only 5 hours 21 minutes. The water used in the different portions of the trial is plotted separately as well as continuously. The reason for the principal pause was that I wished to let the water-level down in the boiler gauge glass, in the hope that the steam might become somewhat dryer in consequence. The actual water used is of course stated only for the times during which it was actually measured and not for the pauses, although the engine continued to run without any alteration of load for the whole period.

The engine ran without a governor, so that it was necessary between each pair of tests to bring down the steam pressure, as is shown on the diagram. The total number of indicator diagrams taken was 142.

On the whole matter I am very glad to be able to say that the working of the engine was satisfactory from beginning to end, and that the results, both as to efficiency and economy for an engine of this size and working non-condensing, were quite first-class.—Yours faithfully,

(Signed) ALEX. B. W. KENNEDY.

Table giving Principal Results of Trial.

Date of trial	April 16th, 1896	
Duration of trial—	hrs.	min.
At full load	5	21
At three-quarter load	1	10½
At half load	1	1
At quarter load	0	54
Dimensions of engine—		
Diameter of high-pressure cylinder	10·02in.	
Diameter of low-pressure cylinder	15in.	
Length of stroke	10·11in.	
Diameter of piston-rod	1·87in.	
Radius of brake to centre of rope	30·7in.	
Boiler pressure at full load	185 lb. per sq. in.	
Horse-power taken up by brake wheel (at 386 revolutions per minute)	1·80	

	Full load.	Three-quarter load.	Half load.	Quarter load.

Mean revolutions per minute	376	363	385	391
Mean I.H.P.	84·1	65·0	45·3	30·1
Mean B.H.P.	75·0	57·0	38·14	23·14
Mechanical efficiency of engine, per cent.	89·2	87·7	84·2	76·8
Feed-water per hour, lb.	1890	1493	1186	969
Feed-water per I.H.P. per hour, lb.	22·5	23·0	26·2	32·2
Feed-water per B.H.P. per hour, lb.	25·2	26·2	31·1	42·0

HORSELESS CARRIAGE NOTES.

AT a meeting of the Engineering Section of the London Chamber of Commerce on Monday, the Light Locomotives Bill came up for consideration, and the recent action respecting the increase of the minimum weight from two tons to four tons was referred to. The resolution passed in favour of this recent increase in weight was on Monday adversely criticised, and the feeling was that two tons for an empty vehicle was the maximum weight it is advisable to sanction at present, and that the heavier vehicle would be unsuitable for what is the experimental stage in a new industry. It was felt that the demand for the greater weight would cause delay in the passage of the Bill. Of course, we hope that this will not be the case, but rather than run any risk of this there is no doubt the majority of those interested in the development of the motor carriage would prefer to leave the maximum for the unloaded vehicle at two tons. A change, if necessary, could be made by an amendment another year, but two tons is sufficient for the carriage of from 30 cwt. to two tons of passengers by motors now available. Since the Monday meeting the four tons has passed the House of Lords, but it has yet to pass the House of Commons.

Great progress was made in the House of Lords on Tuesday, when, on the motion of Lord Harris, the House went into Committee on the Locomotives on Highways Bill.

Lord Harris moved to amend Clause 1 by substituting four tons for two as the maximum weight of unladen vehicles exempted from enactments restricting the use of locomotives on highways. He remarked that the President of the Local Government Board had agreed to make this amendment in deference to representations that had been made to him. Lord Thring agreed that the maximum weight of unladen vehicles should be raised, but he suggested that some limit should be placed on the load that the vehicle might carry, and that there should be flexibility in the Bill to encourage inventions for distributing the weight between two vehicles. The Earl of Kimberley said no doubt many improvements would be made in the development of these vehicles, and power should be given to make bye-laws, as to weight and width of wheel—subject to the consent of the Local Government Board and the Secretary of State—to meet unexpected changes and inventions. Lord Harris said, with regard to weight, the erection of a large number of weighing machines would be necessary all over the country, and obviously in London, and it would be ridiculous to expect carriages carrying persons to be weighed whenever a policeman or some one else demanded it. He did not think Lord Thring's suggestion was a practical one. His instructions were to adhere to the maximum weight of carriage unladen, and not to refer to the weight of a loaded carriage. The other points alluded to he would bring under the attention of Mr. Chaplin. But he would ask their lordships to accept the Bill now, as he was not empowered by Mr. Chaplin to accept any suggestions at present for further amendments in the Bill. The amendment was then agreed to.

Lord Harris then moved to omit the latter part of the clause and insert the following:—"(*a*) Section 26 of the Highways and Locomotives Amendment Act, 1878, shall apply to light locomotives as if they were drawn by animal power, and as so applied shall extend to London; (*b*) a light locomotive shall be deemed to be a carriage within the meaning of any Act of Parliament, whether public, general, or local, and of any regulation made under any Act of Parliament, and, if used as a carriage of any particular class, shall be deemed to be a carriage of that class, and the law relating to carriages of that class shall apply accordingly." Lord Harris said the principle of Section 26 of the Highways and Locomotives Amendment Act, 1878, had been extended by Section 41 of the Local Government Act, 1888. The former section empowered local authorities to make various regulations as regarded width of wheel, skids going down hill, and other matters. It had been pointed out that the clause was not clear as to the law that would apply. It was considered doubtful whether the Inland Revenue could levy a tax for this class of carriage, and the clause had been amended to make it perfectly clear that, whatever the kind of carriage might be, and whether the Act of Parliament was a public, general, or local Act, the Act and any regulations under it would apply to these carriages. The clause, with the proposed amendment, was agreed to.

Lord Harris moved to amend Clause 2, which regulates the keeping and use of petroleum or any other inflammable liquid by substituting £10 for £2 as the fine for any breach of the regulations. He remarked that it had been considered that a penalty of £2 was not sufficient, and that it was desirable to make it heavier. The clause, with this amendment, was agreed to.

Lord Harris moved to omit from the Bill Clause 3, which provided a penalty of £10 for negligently driving a light locomotive or suffering it to be without due control. He said that the statutory provisions which the House had approved in Clause 1 rendered this clause unnecessary, for the ordinary law as regarded negligent and furious driving would apply as much to locomotives as to any other kind of vehicle. The omission of the clause was agreed to.

Clause 4, which provided that the Local Government Board may make regulations for the use of light locomotives, and a fine of £10 may be inflicted for any breach, was also agreed to, as well as the insertion, after Clause 4, of certain new clauses of a consequential character. The Bill then passed through Committee.

THE American Motor League has been organised for the purpose of advancing the interests and use of motor vehicles. This is to be done "by reports and discussions of the mechanical features, by education and agitation, by directing and correcting legislation, by mutual defence of the rights of said vehicles when threatened by adverse judicial decisions, by assisting in the work of constructing better roads, better sanitary and humane conditions, and in any other proper way which will assist to hasten the use and add to the value of motor vehicles as a means of transit." The officers will include a president, secretary, treasurer, and attorney, and a vice-president from each State having more than 100 members of the League. Annual meetings will be held for reading and discussing papers, and considering plans bearing upon the work of the League. The membership fee is 1 dollar per year, with an entrance fee of 2 dollars—4s. 2d. and 8s. 4d. respectively. Mr. Charles E. Duryea, of the Duryea Motor Wagon Company, is president; Mr. J. Allan Hornsby is secretary; Mr. Charles B. King, treasurer; and Messrs. H. D. Emerson, H. P. Maxim, and H. G. Morris are vice-presidents.

ROYAL METEOROLOGICAL SOCIETY.—The monthly meeting of this Society was held on Wednesday evening, the 20th instant, at the Institution of Civil Engineers, Great George-street, Westminster, Mr. E. Mawley, F.R.H.S., president, in the chair. Mr. R. H. Curtis, F.R. Met. Soc., read a paper on the exposure of anemometers, in which he gave the results of a comparison of the records from the three anemometers at Holyhead, viz., the Robinson, the bridled, and the pressure-tube anemometers. It was clearly shown that the force of the wind is greatly affected by surrounding objects. The author is of opinion that for anemometrical records to be reliable and of value not only must the instrument be exposed in an open place free from local obstructions, but it is also absolutely essential that the stand which carries it shall offer practically no resistance to the wind, and that the instrument should not be placed on the roof of a house. The paper was illustrated by a number of lantern slides. An interesting collection of photographs of clouds sent to the Society by Mr. H. C. Russell, F.R.S., of the Sydney Observatory, was also exhibited.

AMMONIA ICE-MAKING PLANT, SHEFFIELD

THE PULSOMETER ENGINEERING CO., LONDON, ENGINEERS

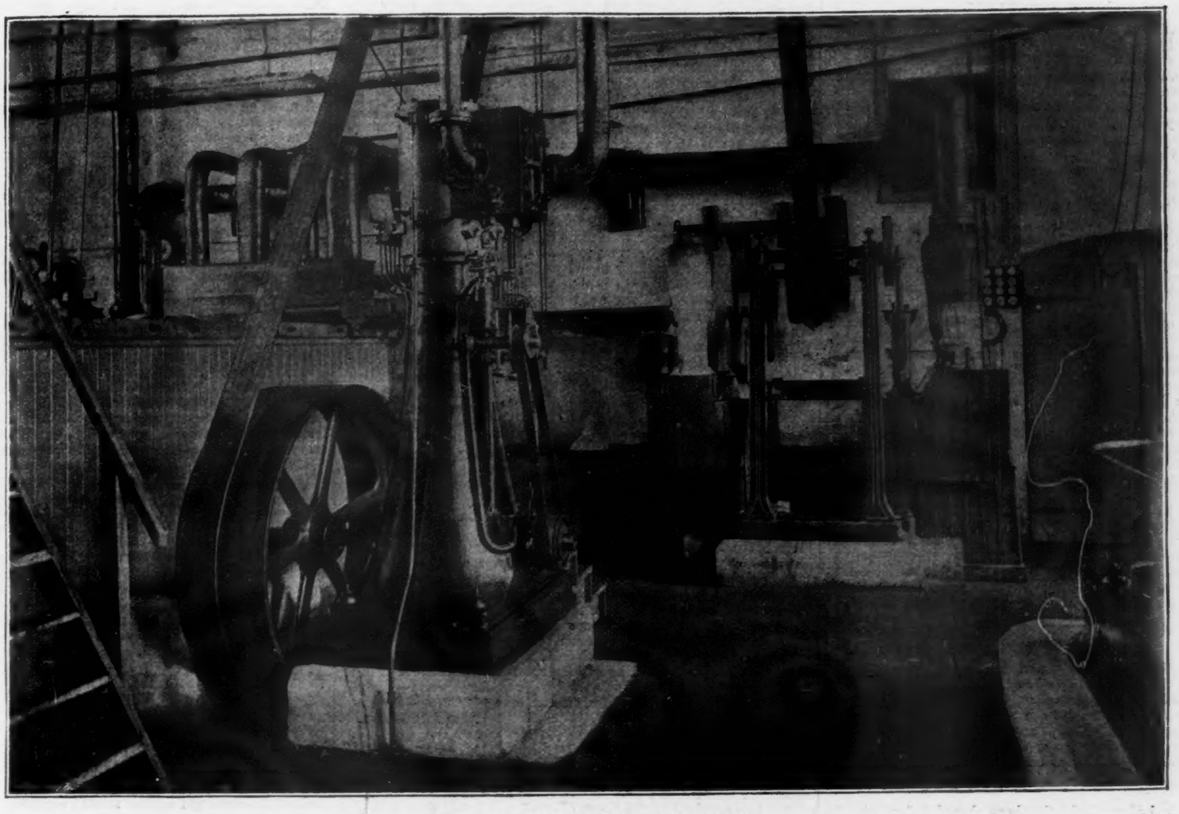

Fig. 2 AUXILIARY ENGINE AND PUMPS

AMMONIA COMPRESSION ICE-MAKING AND REFRIGERATING PLANT.

The Sheffield Pure Ice and Cold Storage Company of Bank-street, Sheffield, ordered last year from the Pulsometer Engineering Company, of Nine Elms, S.W., a large ice-making and cold storage plant, of which we now give illustrations. It was required by the contract that the plant should produce not less than 20 tons of hard transparent ice every twenty-four hours, in blocks weighing about 5 cwt., and of a thickness of not less than 12in., and this with condensing water at a temperature of 68 deg. Fah. The machine had also to maintain continuously 70,000 cubic feet of cold storage space at a temperature not exceeding 21 deg.; the coal consumption had also to be guaranteed. On a trial which extended over two months we understand that the output was considerably in excess of that specified, while the coal consumption was less.

The boiler is of the Lancashire type, constructed of mild steel and to pass Lloyd's Rules for a working pressure of 110 lb. per square inch. Water circulating cross tubes are fitted in the two flues. The sizes of boiler and grates are specially arranged so that a poor quality of coal can be burned. The donkey pump is of the contractor's Deane pattern, mounted on a cast iron tank supplied with the usual ball valve, and water from the main.

The engine is of the horizontal compound side-by-side type, driving the ammonia pumps tandem. The high-pressure cylinder is fitted with automatic cut-off expansion gear, and the low-pressure cylinder with an ordinary slide valve. The surface condenser, which is placed between the engines, is fitted with brass tube plates and tubes with screwed ferrules. The air pump and water circulating pump, together with the feed pump, are driven from the crosshead of the low-pressure cylinder by means of bell-crank levers. The ammonia pumps, which are of the contractor's latest pattern, are of the double-acting type, and are cast in special metal, and are fitted with special suction and discharge valves, without springs. The gas condenser is placed above the engines in a large wrought iron tank, and consists of extra heavy wrought iron tube tested to 2000 lb. per square inch. The connecting branches and tees of this condenser are made of wrought iron wherever they come in contact with ammonia.

On the engine-room floor, in a wrought iron tank carefully lagged with charcoal and wood, are placed the refrigerators, so as to be close to the ammonia pumps. These refrigerators are also of extra heavy pipe, and the couplings and tees are also made of wrought iron. Between the ammonia pumps and refrigerators are placed two large steel receivers. These are made from mild steel and welded up, the usual cast iron receivers being entirely dispensed with on account of the risk attaching to them.

The illustration Fig. 1 gives a very fair idea of the engines and pumps. Fig. 2 shows clearly the auxiliary engine which is used for driving the various parts of the machinery when the main engine is not running. It also shows the two brine pumps. These brine pumps are of the double-acting type fitted with brass valves, liners and rods, and are provided with first and second-motion shafts, with mortice gearing. The water pump, which is of a similar design, cannot be seen on the illustration. This water pump draws from a large dam or reservoir just outside the engine-room, and discharges into the condenser tank.

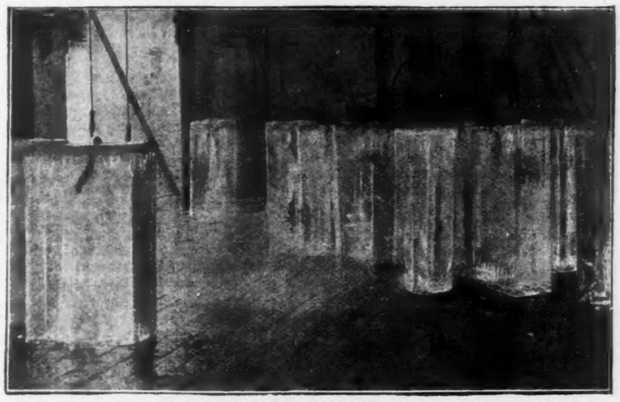

Fig. 4—THE ICE HOUSE

Fig. 3 gives a view of the ice house looking towards the engine-room, and is sufficiently clear to describe itself. We may mention, however, that the ice is of beautiful quality.

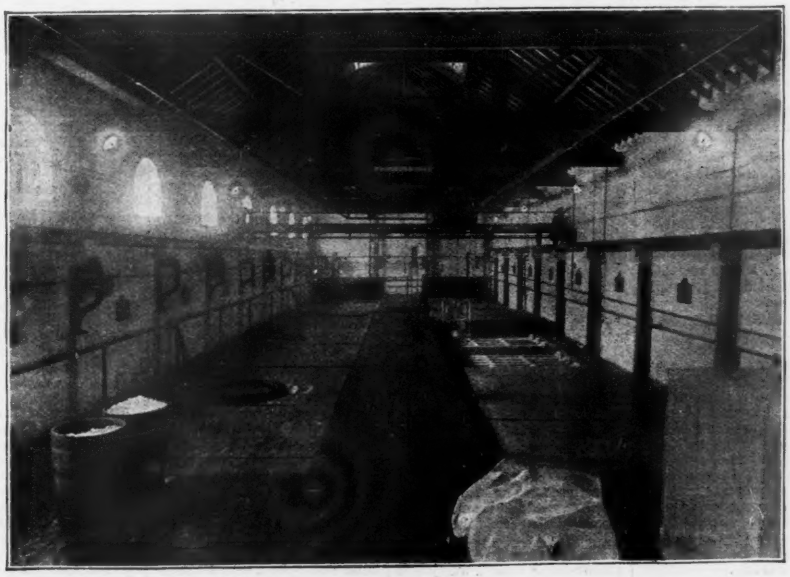

Fig. 3—THE ICE HOUSE

Fig. 4 shows the other end of the ice-house, with a view of the crusher and some of the ice. At this end is placed a circular saw for cutting up the blocks required. The ice is lifted and removed from one end of the building to the other by handy rope travelling cranes with both horizontal and cross travellers. The cold rooms are fitted with brine coolers, and are supplied with brine from one of the refrigerators. The atmosphere in the rooms is perfectly clear and cool and dry. The total capacity of these rooms is about 70,000 cubic feet.

The building is fitted throughout with electric light and the cold rooms are served by an hydraulic lift.

The whole of the work is finished in the best style, and has been running without the slightest hitch since it has been taken over.

THE CHANNEL SQUADRON.

This squadron, which comprises eleven warships and a number of torpedo-boat destroyers, under command of Vice-Admiral Lord Walter Talbot Kerr, with Rear-Admiral Armand T. Powlett second in command, arrived in the Clyde on the 19th inst. The fleet left Luce Bay, off the Wigtonshire coast, where they had been anchored since the 16th inst., at half-past six o'clock on the morning of the 19th, and about 5.30 in the evening they anchored at the Tail of the Bank. With a total weight of exceeding 100,000 tons the present combination of British warships is by far the strongest ever amalgamated as a Channel Squadron. In all there are seventeen vessels, including six battleships, each over 14,000 tons displacement. Of these the Majestic and Magnificent are the most powerful battleships afloat, and the largest as well, if the 15,300-ton ships Italia and Lepanto of the Italian Navy are excepted. Besides these two great battleships the squadron comprised the battleships Empress of India, Royal Sovereign, Resolution, and Repulse; the twin-screw cruisers Blake, of the first class, and Bellona, of the third class; the first-class twin-screw gunboat Halcyon; the first-class twin-screw torpedo boat Speedy; and the torpedo-boat destroyers Lightning, Surly, Decoy, Sunfish, Hardy, and Sturgeon. The crews of the fleet number roughly about 5500 hands. The visit on this occasion coincided with the Queen's birthday holiday in Glasgow and the neighbourhood, and the weather being favourable, the number of visitors inspecting the vessels was enormous. As on former occasions, the tars were entertained both at Glasgow and Greenock, and arrangements for the enjoyment of the officers were also carried through. It so happened that H.M.S. Benbow, the Clyde guardship, had not yet returned to her station at the Tail of the Bank, and as a consequence there were no formalities on the arrival of the squadron, but at noon on the 20th all the vessels were bedecked with flags in honour of her Majesty's official birthday, and a royal salute of twenty-one guns fired from the vessels. The squadron departs early on Saturday (to-morrow) for Stornoway.

H.M. cruiser Barham is to receive a set of Thornycroft water-tube boilers in the place of her old locomotive boilers. The Admiralty have decided to expend £28,218 on her refit.

LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

LOCOMOTIVE FIRE-BOXES.

SIR,—I have read with much interest your leader on this subject in your issue of the 8th inst. Nevertheless, there are one or two points on which I should like to add a few words.

In the first place, I think you decidedly under-estimate the average life of a locomotive boiler. On one of our largest railway companies no complete examination of a boiler is made until it has been at work five years, and even then, as a rule, the only repairs that are required are the replacing of a few fire-box stays, and, in some cases, of the fire-hole ring rivets, the heads of which are apt to be burnt. After this a complete examination is made every three years, and the boilers frequently last twenty years or more in constant use before being removed, with a mileage of about 500,000 or 600,000 miles.

The questions of the crushing of top rows of tubes in the copper tube plate, and that of the use of sling stays, are really only one. I know of no case of the holes becoming flattened where the sling stays have been well up to their work, but where the slings stays are broken or slack, the load on the tube plate certainly does crush it, causing the tubes to become oval. It is not very obvious how any load comes on to the sling stays, as the inside fire-box will certainly expand slightly more than the shell. Probably the bridge stays themselves deflect a little, and the foundation ring certainly does, causing grooving in the plates just above it, and a tendency to leak at the corners. Also the copper box is in compression, while the shell is in tension, and the effect of this is not negligible over a length of several feet.

The advantage of the Belpaire system of staying is undoubtedly due to the fact that instead of a large part of the whole load on the fire-box crown being taken through the foundation ring, it is taken direct by the through stays, thus saving grooving in the saddle plate, and just above the foundation ring, and probably diminishing to a very great extent the breaking of the screwed stays in the water space. A lesser advantage is that the roof of the inside fire-box is not nearly so much encumbered as in the ordinary method of staying.

I hope that others who have had some experience with locomotive boilers will give their opinions on this subject.

39, Dairy House-road, Derby, May 18th. C. E. WOLFF.

DUTY OF PUMPS.

SIR,—I think it is quite a new experience for engineers to learn that, by lowering the consumption of coal utilised by an engine, its duty will be diminished. Nevertheless, this, the latest enigma, is implied in the formula for the duty of an engine quoted by your reviewer from the work on "Pumps and Pump Motors," by P. R. Bjorling, in your last week's issue, where it is stated that the duty of an engine using 5 lb. of coal per horse-power hour is $= \frac{5 \times 1,980,000}{112} = 88,214 \cdot 28$. Your reviewer finds fault with a point of arithmetic, but overlooks the above absurd statement. In this expression the duty is made to be directly proportional to the coal used, instead of being inversely as that quantity. The question seems so simple that one would hardly think such a mistake possible, and in its simplest form it may be stated thus:—Work done per pound of coal $= \frac{1,980,000}{5}$, and therefore for 1 cwt. $= \frac{1,980,000}{5} \times 112 = 44,352,000$ foot-pounds, which I venture to give as the correct duty of this engine. J. B.

London, May 13th.

PERMANENT WAY.

SIR,—I notice in the correspondence on above, "F. J. P." criticises what I have suggested under the designation of "an altered form of permanent way." He prefers to define it as a "mixture of the old G. W. R. longitudinal road—which he states they have condemned and are doing away with—and of the present sleeper road." But, query, is not this "an altered form?" So there seems to me but trifling ground for objection, whilst he appears to overlook what I aim at, viz., a combination of the good points of both, viz., the continuous homogeneous rail-bearing of the first, and the greater resistance offered by the last to transverse oscillation, and greater bearing power besides.

I find that objection is taken to the use of the flat-bottom Vignoles rail on the longitudinal sleeper on the ground that the rail crushes into the sleeper through the pressure being applied in the direction of the fibres. But the pressure is similarly applied to transverse sleepers actually, and in the case of two 30ft.—4in. base—Vignoles rails the area to support the load = 20 square feet, while 20 chain, 1ft. 3½in. long by 6¼in. broad = 14ft. 6in. bearing, or 0·27 less bearing area to carry the load! To meet the objections made I suggest the selection of a harder grained wood for the longitudinal than was formerly used; and possibly the timber quoted by "F. J. P." as used in Argentina for sleepers, and which he describes as nearly "as hard as boxwood," would be very suitable. Perhaps in some further future communication he will kindly give the name of this wood, and from where it is supplied and its cost. Such statistics will be valuable in connection with the general interests of this subject.

The steel chair, of which an illustration is given in last week's ENGINEER, is formed, I notice, in the same simple manner that wrought iron chairs were made in the United States of America thirty years ago, a flat plate with the four corners perforated for spikes, and the central portion nicked at the sides, and turned up to clip the rail—or, as in the present case, the rail and the wood key. I think it preferable, however, to do away with the chairs altogether, so that the rails shall bear wholly on a wooden cushion, and which, as I increase its thickness, must add to the smoothness of travel of the load.

I join issue with "F. J. P." as to the impossibility of packing the extra sleepers I advocate, and venture to assure him that it is quite practicable.

Briefly summed up, what I suggest (1) will give continuous and uniform bearing to the rails; (2) will enable lighter rails to be used in place of increasing their weight per yard; (3) give increased bearing area, primarily, to the rails, and finally to the sleepers; (4) create a track which, when made, will cost less to maintain than in existing practice; (5) diminish number of detail items per mile; (6) get full service out of the ballast bed.

3, Derby-road, Hightoun, Wrexham. J. H. R. ROSE.

SIR,—In a recent leading article in THE ENGINEER there appears the following statement:—"We have not the least hesitation in saying that a first-class road cannot be made with flanged rails spiked to cross-sleepers." It would have seemed to me that roads of this construction which carry, as do several in the United States, heavier trains at higher speeds than any which are run in this country, are at least high enough class for all practical purposes. But I did not take up my pen merely to say this. It occurred to me that the purport of a conversation I had last summer with two very distinguished American railway men, the one the president of one of the principal companies, the other the first vice-president of a yet greater company, would be of interest to your readers in this connection. Here is a rough sketch of our dialogue.

Vice-President: Your roads won't do for our traffic.

W. M. A.: I don't understand.

Vice-President: They're not strong enough.

W. M. A.: Well, I always understood that our chair roads were accused of being extravagantly costly, but I thought they were admittedly better and stronger than your Vignoles system. Do you deny this?

Vice-President: Certainly I do. They possess no advantage to set against the increase of cost. And, mind you, I speak from experience. We took out from England two or three miles of standard North-Western road, rails, chairs, fastenings, and everything complete. The only thing we did not import was the ties themselves. We took out likewise North-Western permanent way hands, and they laid their own road in our main line alongside of our own standard pattern of road. And so we tested the two systems side by side. Your system not only was much more difficult to maintain, but was so knocked about by our heavy traffic that after a year or two we had to take it out, while our own road of the same age was still in perfectly good condition.

W. M. A.: Well, you surprise me.

Vice-President: The truth is, your chairs make too rigid and unyielding a road. Our system with the rails resting directly on the ties gives an elasticity that spares both road and rolling stock.

W. M. A.: Then if I understand rightly, your position is, that we are making just the same mistake that the old engineers made when they fastened their rails straight down on to granite blocks, or even in some cases direct on to the live rock itself.

Vice-President: Precisely so, only of course in a less degree. I may say that we don't even use tie-plates, so that our rail rests direct on the soft elastic wood of the sleeper.

President: I quite agree with all that Mr. —— has said. Of course you must remember that we are not talking about the weak Vignoles rails with wide-spaced sleepers that one sees on the Continent, and that our roads are laid with about 90 lb. rails, and besides, have a tremendous lot of wood in them. You here in Europe put ten or eleven sleepers under a 30ft. rail where we should put at least fifteen. In the main line my company have as many as sixteen or seventeen ties under each rail—in fact, I'm not sure whether we haven't lately gone as far as to use eighteen.

W. M. A.: Well, I must confess this is a perfectly new light to me. I should be interested to know what our English engineers would say to it.

Vice-President: Why, Mr. Eddy, who was trained on the English system, has come back from Australia a convert, and declares that chair-roads are a mistake.

Such, Sir, was the upshot of our conversation as accurately as I can remember it; and, as it made a great impression on me at the time, I do not think I am likely to be far wrong in my recollection. I do not, of course, presume to express any opinion of my own upon a technical subject. But I will just say this: English railway men fought hard against continuous automatic brakes; they have had to acknowledge themselves wrong. They fought hard against bogie carriages. Mr. Patrick Stirling probably died unconverted, but he has left no successor. Is it not possible that in standing out against the opinion of the civilised world—I ought perhaps to make an exception in the case of France—they are wrong also? W. M. ACWORTH.

47, St. George's-square, S.W.

SIR,—I notice in the last number of THE ENGINEER a letter from Mr. J. W. Wilkins, in which he alludes to my remarks on the cause of the late accident to the Leeds express, and infers that even if a train load of ballast had actually been standing in a siding near by, with the necessary labour at hand and opportunity to distribute it, that ballast would not have been made use of in time to prevent the accident; he further proceeds to say that if the ballast had been properly placed in contact with the sleepers, that catastrophe might never have happened.

I need not allude to his remark as to the ignorance of one M. Inst. C.E. of the art and mystery of platelaying; his exposition thereof will no doubt be appreciated by many members of that Institution. I may say, however, that Mr. Wilkins' statement constitutes a very grave charge against the officials in charge of the permanent way when the accident occurred; but I leave them to fight their own battle.

My previous letter was based on Major Marindin's report as quoted in the newspapers, that the accident was attributable to a deficiency of ballast; and this apparently is also Mr. Wilkins' opinion. I pointed out how this deficiency could have been made good in a rapid and economical manner; of course, if the officials purposely omitted to deposit the ballast which the Government inspector considered to be necessary, there is no more to be said. Mr. Wilkins concludes by saying that he has very good reason to object to the machine depositor, spreader, and trimmer, when intelligent and decently-paid hand-labour can be obtained. I am afraid that, in spite of the "good reasons" alleged, mechanical work is rapidly supplanting hand-labour in many branches of industry, and probably before long the operation of ballasting will be no exception to the rule. JAMES FFORDE.

17, Victoria-street, S.W., May 19th.

SIR,—Once upon a time there was a giant who performed before all the crowned heads of the world, more or less. In his exhibition the giant stood upon the heads of two ordinary men and swung clubs, and performed other antics. His legs were well separated, his feet turned outwards, and the heels of his boots were deep so that they would not slip over the heads of his supporters. The supporters also stood with their legs apart—so as to increase the base as much as possible—and they had their boots stuck under bent nails in the floor of the stage, further to increase the stability of the whole. The giant's weight increased, and he took to heavier clubs, and operated them more furiously, so that the manager of the entertainment was obliged to get two bigger men to support the giant; their feet were spread as far apart as possible and pushed into straps secured to the stage floor. The giant complained that the heads were not steady enough to enable him to do as he would like, and that he never could tell exactly how far apart they would be at any time during his performance.

The stage manager decided that some change must be made. He knew that two still bigger men would not do, even if he could get them, because he saw that lengthening the man only increased the leverage on the feet attachments, and he had broken several of these already. So he got two high-backed chairs and fastened them securely to the stage opposite each other, with the backs outwards. He then made the two supporters sit sideways on the chairs facing the audience, and he stuffed a hard old-fashioned sofa cushion between the side of each man's head and the back of his chair. The giant said that would give them the support just where they wanted it, and on trying the arrangement he was delighted to find that the men's heads did not wobble about and could be depended upon, and that he was able to use heavier clubs than ever, and to perform various surprising feats with a feeling of security that he never enjoyed before. FOUR-FOOT.

May 18th.

SIR,—It will be plain from letters which have already appeared in THE ENGINEER, that I consider the hold which a sleeper has upon the "formation" of a line of railway is not always adequate to retain it in position on the passage of heavy trains at great velocities. It will be admitted that the only means at present depended on is the friction set up between the under side of a straight sawn sleeper and the small area of ballast in effectual contact with it; and even this will greatly depend upon the kind of ballast used. The small friction of ballast filled in against the edges of the sleeper and boxed against the end of it may be left out of the calculation altogether.

No great stretch of imagination in the way of design was required, when once the idea was accepted that more friction was desirable; and I will just say what under these circumstances presented itself to me as a means to that end. I suggest an attachment in the form of T iron, or like a V with ears to allow it to be spiked to the underside of the sleeper below each rail; or, what would perhaps be nearly as effective, and less costly—the diagonally sawn half of a block of wood, 5in. by 5in., spiked flat across the sleeper. This sort of arrangement would offer more than twice the resistance to lateral motion that fully boxing up does; beside the advantage of the sleeper being—so to say—"let into" the solid, and the additional advantage of its being always there. Then possibly the navvy might "open out," and leave opened out with impunity. J. W. WILKINS.

May 20th.

EVAPORATORS.

SIR,—You refer, in your remarks on the above subject, to the necessity for keeping a regular control over the volume or weight of the supplementary steam raised in the evaporator and passed to the boilers. Besides the system for determining this quantity pointed out by you, there is another very simple arrangement which I have had occasion to recommend in more than one instance, and which answers satisfactorily. Steam will be admitted to the coils of the evaporator at a known pressure, and, consequently, temperature; and the condensed steam resulting will be drained off, say, at atmospheric pressure in a continuous stream. It is only necessary to pass this rejected water over an accurately constructed tumbling bay, or through any of the trustworthy self-registering meters which exist, to know at any time what is the weight of steam which has been used inside the coils, and to deduce from this the amount of vapour raised. The simple theory of the operation would be of course this: Supposing steam is admitted at an average pressure of about 20 lb.—there is little advantage to be gained by using steam of very high pressures for mere evaporating work—or a total temperature of about 1192 deg., then 980 deg. will have been employed in the coils. Say that the water in the evaporator has been raised from 45 deg. to the temperature of steam at about 8 lb. = 1185 deg., it follows that every pound of condensed steam discharged should correspond to ·86 lb.—nearly—of supplementary steam passed to the boilers.

The actual result will not be precisely the foregoing, as there are various disturbing influences which come into play. For instance, the steam will probably not be admitted to the coils perfectly dry, and against this the condensed steam had a temperature higher than 212 deg. immediately before its discharge. Further, there is naturally an amount of heat lost in the course of the operation. But these things being fairly constant in a given apparatus, it will suffice to establish a coefficient, preferably by direct experiment, and the amount of steam passed to the boilers can be checked at every moment with an accuracy and ease which leave nothing to be desired. E. STEPHENSON.

Hornsey Rise, May 18th.

THE LIQUEFACTION OF GASES.

SIR,—I do not think anything would be gained by continuing the discussion of the action of the Linde or Hampson process with your correspondent "Cryos." If he will read any good treatise on thermodynamics he will find most of his difficulties cleared away. He evidently has not read what has appeared in THE ENGINEER on the subject, nor has he heard or read Dewar's last lectures. Indeed, he does not appear to read anything with care; thus, for example, I said that no external work was done in the Hampson apparatus, and he immediately calls my attention to the compressing pump. That is not part of the Hampson apparatus, and is indeed only a pump used by the Brin's Oxygen Company, utilised for the purpose. Dewar uses the Hampson or Linde process without a pump. Why "Cryos" should insist on the need for the Joule effect is a puzzle to me, seeing that the mere expansion of air will give him ten times as much cold. If Dr. Hampson depended on the Joule effect, he might pump for a century before he got liquid oxygen, much less liquid air.

"Cryos" seems to be quite unaware of the fact that it is more than doubtful that any Joule effect whatever could be got in the apparatus used, which has little or nothing in common with that employed by Lord Kelvin.

"Cryos" must try again to master the theory of the Linde process. When he has done that he will see that his remarks about temperature in the two ends of a tube are beside the mark.

May 19th. ZERO.

SIR,—If your correspondent, "Cryos," will take the trouble to think the matter out, he will see that the work done on the air pump piston by the low-pressure air during the suction stroke must all reappear on the compression side. The effect will be as has been pointed out by Schröeter, that the work to be done by the compressing engine is reduced. By no stretch of definition can this be called external work.

It seems to have escaped "Cryos's" attention that very great doubt exists as to whether there is any such thing as "Joule's effect." The experiments of Kelvin and Joule are by no means unimpeachable.

If "Cryos" can refer me to any authority who has proved by direct experiment that the figures he gives in his fourth paragraph are accurate, I shall be obliged to him. At present, I believe they are pure deductions, with no foundation in ascertained fact. J.

May 20th.

PUFFING BILLY *v.* NO. I.

SIR,—There appear to be one or two errors in your note *re* the above. (1) At the time the loco was put up on the High Level Bridge the Newcastle papers stated that it was No. 1—Stockton and Darlington—removed from Darlington, unless I am much mistaken; but as this was fourteen years ago there is room for doubt on my part. (2) Puffing Billy was not built by Stephenson but by Hedley, of Wylam. As my authority, I may say I had this from an old millwright, who had worked for Hedley on Puffing Billy. Puffing Billy was the first loco to run on smooth rails and without a rack, and followed Hedley's experimental truck. The two engines are very much alike at a casual glance. I saw Puffing Billy under steam at the North-East Coast Exhibition, Tynemouth, 1882, but what became of it after that I am not quite sure. GEO. S. PARDOE.

81, Harrow-road, W., May 18th.

(*For continuation of Letters see page 527.*)

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.—The summer excursion of this Institution will be to Cardiff and district. Arrangements have been made with the North-Eastern Railway Company to run a special train to Cardiff, *viâ* Leeds, Crewe, and Pontypool-road, on the 22nd of June, calling at Sunderland and Stockton-on-Tees, and will return from Cardiff at about 9.30 a.m. on Saturday, June 27th.

SEWERAGE OF WESTGATE-ON-SEA.—The Rural District Council of the Isle of Thanet, Kent, at the desire of the Parish Council of Westgate-on-Sea, have instructed Mr. E. Bailey Denton, M. Inst. C.E.—Messrs. Bailey Denton, Son, and North, of Palace Chambers, Westminster—to immediately prepare plans for the sewerage of this favourite seaside resort. The method of disposal has been for some time past a bone of contention amongst the inhabitants, but it has now been decided to pump the sewage into the main outfall sewer of the Borough of Margate, discharging into the sea at the North Foreland, should the terms imposed by that borough prove acceptable to Westgate. Failing this, the sewage will be raised to and utilised upon the marsh lands beyond Birchington. The works will not be commenced until October, but will be finished by April, 1897, so as not to interfere with the popularity of next year's summer season.

RAILWAY MATTERS.

THE Belgian Chamber of Representatives has guaranteed the issue of Congo Railway Bonds.

ON the London and North-Western Railway a new type of detonator, known as the "Duplex," will henceforth be used throughout the system for fog-signalling purposes in place of the ordinary detonator hitherto employed. Instead of putting two fog-signals on the rail, ten yards apart, only one of the new design will be used, and, of course, there will thus be but one report.

WRITING on the steam tramways in Italy, a tramway manager in Italy states in reply to a letter by Mr. Armstrong, suggesting to a contemporary the adaptation of steam tramways as used in Italy to the purpose of the proposed light railways in England, that the modifications he considers as "easy" would have to be such as would eventually turn a "tramway" into a "railway," or, if the comparison is suitable, a "mouse" into a "rat." Most tramway and railway engineers will only partly agree with this.

A GENERAL classification of the accidents on the American railways in March shows the following:—

	Collisions.	Derailments.	Other accid's.	Total.	p. c.
Defects of road	0	10	0	10	8
Defects of equipment	10	15	4	29	21
Negligence in operating	24	2	0	26	19
Unforeseen obstructions	0	15	1	16	12
Unexplained	23	20	0	53	40
Total	57	72	5	134	100

THE vote in the Brussels Chamber, May 15th, on the Congo Railway Bill, passes a Bill which provides an immediate loan of 5,000,000f. to take up that now due, and the guarantee of a further loan of 10,000,000f. at 3 per cent., practically secures the success of the enterprise. The station at Tumba, a distance of 187 miles from the starting-point at Matadi, will be opened in July, and the directors confidently anticipate that the traffic receipts on this section of the line will in a few months give such results as will enable the company to raise the 20,000,000f. still necessary for the completion of the line to Leopoldville, without having any further recourse to State assistance. The *Times* says the Government have, indeed, given their formal pledge not to exceed the limits of the present measure.

THE record of train accidents in the United States in March includes 57 collisions, 72 derailments, and five other accidents, a total of 134 accidents, in which 28 persons were killed and 95 injured. These accidents are classified by the *Railroad Gazette* as follows:—Collisions: trains breaking in two, 10; misplaced switch, 8; failure to give or observe signal, 1; mistake in giving or understanding orders, 4; miscellaneous, 11; unexplained, 23; total, 57. Derailments: Broken rail, 5; loose or spread rail, 2; defective bridge, 1; defective switch, 1; bad track, 1; broken wheel, 1; broken axle, 5; broken truck, 6; failure of drawbar, 1; broken car, 2; runaway train, 1; derailing switch, 1; animals on track, 1; landslide, 2; snow or ice, 5; washout, 1; malicious obstruction, 1; maliciously misplaced switch, 2; accidental obstruction, 3; unexplained, 30; total, 57. Other accidents: Boiler explosion, 1; cylinder explosion, 1; breakages of rolling stock, 1; other causes, 2; total number of accidents, 134.

THE passing of the preamble of the Sheffield District Railway Bill knits various collieries and villages with the M. S. and L., at Woodburn Junction, and in that view of it will be useful. Bus that could not be the whole that was meant by the Bill. By means of what is known as the East to West Railway, the new line, if sanctioned as applied for, would have given the Great Eastern access to Sheffield. The Committee, by refusing running powers into the Victoria Station, do not prevent the Great Eastern passengers getting to Sheffield, but they certainly make it considerably more inconvenient for that company. At the same time, although local evidence was strongly in favour of the District Railway Bill, it is undeniable that the Victoria Station of the M. S. and L. is an awkward one to deal with, and admittedly inadequate for the traffic at present passing through it, that will be enormously increased by the company's new line to London, in view of which extensive additions are at present being arranged for.

IN a report on a collision which occurred at 10.16 p.m. on the 2nd ult. at the London-road Station, Manchester, on the Manchester, Sheffield, and Lincolnshire Railway, when the 10.15 passenger train was leaving the station, from No. 3 platform, it came into collision with a light engine which was standing outside the station on the same line as the train had been signalled to leave by, a Board of Trade inspector says:—"This accident was primarily due to the forgetfulness of signalman Paine, on duty in the station cabin, who, within a few minutes of having placed a light engine upon the loop line, lowered the starting signal for the 10.15 p.m. train to leave the station on the same line. I understand it is proposed to put the following rule in the appendix to the company's time-book, which should prevent any future misunderstanding on this point:—'Drivers of all engines on arrival at London-road Station after dark must immediately place a red tail lamp in front of the engine, so that when the engine moves in the opposite direction such red light will act as a tail lamp.'"

AN important railway improvement, which has been in progress for some years past, was successfully completed on Monday, when the new southern tunnel approach to New-street Station, Birmingham, was thrown open to traffic. The object of the extension is to give to the North-Western and Midland Companies independent approaches, and to do away with the system of joint lines and crossings of rails on the level, which has made the traffic so difficult to work, and which was the cause not only of frequent delays, but of some danger. Up to the present the whole of the trains of the two companies entering and leaving the station on this side—some 400 a day, or an average of one in every 3½ minutes—have had to use one tunnel with but one up and one down line. In such circumstances, the wonder was that the traffic worked so smoothly as it did. Now, however, the Midland station will be entered through the new tunnel, and the London and North-Western and Midland trains will in no case use the same line of rails. Exclusive of permanent way and signals, the purchase of land and buildings, the work has cost about £100,000, while the total outlay has been something like £250,000.

THE Bill promoted to extend the time for the purchase of lands for the purposes of the City and South London Railway Act, 1893, and for the completion of the underground railway and other objects, came before a Select Committee of the House of Commons on the 18th inst. The main question before the Committee was the demolition of the Church of St. Mary Woolnoth, in King William-street, near the Bank of England, for the purpose of erecting a station. Amongst other witnesses called was Mr. C. G. Mott, chairman of the company, who said the church was not wanted. There were ten churches within a radius of 200 or 300 yards, two of them being actually in the same street as St. Mary's. Besides, St. Mary's had no congregation and there were no peculiar associations connected with it. It merely resembled a room in the Mansion House. The money that would be paid for it would be sufficient to enable several other churches to be built in districts where churches were wanted and where congregations could be easily obtained. If the church were left standing the company would not have as useful a station as would otherwise be secured, and the cost of the works would be increased. The Committee found the preamble of the Bill proved, subject to the insertion of a clause for the protection of St. Mary Woolnoth, and declaring that it shall be referred to the arbitrator to take into consideration the additional liability which will devolve on the company in consequence of giving up their present rights.

NOTES AND MEMORANDA.

IN a recent paper read before the Paris Academy of Sciences, on the theory of gases, by M. J. Bertrand, a critical examination of the well-known formula of Maxwell for the relation between the velocities of the gaseous molecules and their components in any arbitrarily chosen direction is given. This formula is described as necessarily absurd, since it gives an apparent solution of a problem insoluble from its very nature.

FLOUR mills in New South Wales employ about 700 hands, with machinery and plant worth £244,365, while the Colony's breweries employ 744 persons, and possesses machinery and plant to the value of £122,000, with an annual output of about 10,000,000 gallons. There is a growing industry in connection with the making of butter and cheese, in which about 1000 persons are employed, the butter factories having machinery and plant to the value of over £50,000.

FROM some experiments made to determine the best angles for the heads of countersunk rivets for ships' plates, Professor Weighton concludes that for ¼in. plates the countersink should not be less than 56 deg., and even a greater angle would seem to be not amiss; and second, that for ½in. plates the countersink should not be less than 35 deg. For other thicknesses the angle of countersink would be in proportion, and the following would be about the angles proper for the different thicknesses:—¼in. plate, 56 deg. angle of countersink; ⅜in., 45 deg.; ½in., 35 deg.; ⅝in., 26in.

THE manufacture of sugar in New South Wales is an important industry, and its record shows it to be a progressive one, but the business is falling gradually into the hands of large establishments. In 1882, 70 mills worked by steam and 16 by cattle manufactured 270,000 cwt. of sugar and 560,000 gallons of molasses, while in 1890-91, the year showing the largest yield, 31 steam and two cattle mills manufactured 530,660 cwt. of sugar and 1,074,080 gallons of molasses; the number of hands increased in the same time from 1039 to 1621. Last year there were two refineries, melting 756,200 cwt., possessing machinery of 650-horse power, and employing 440 hands.

THE British Consul at Jerusalem writes that since the opening of the railway between Jaffa and Jerusalem the necessity for a harbour at Jaffa has become all the more urgent, and sooner or later it will have to be constructed, or the Jaffa-Jerusalem railway will have to be extended to Port Said. As far as tourists are concerned, the advantages of a connection by rail with Port Said would be very great, for the intervening country being perfectly level, the distance—about 220 or 230 miles—could be accomplished in ten hours. Jerusalem could thus be visited without the necessity of a sea voyage to Jaffa, where in rough weather the landing is uncertain; and travellers on their way to or from India and Australia would also have an opportunity of seeing the Holy Land by breaking their journey for a few days at Port Said.

THE application of aluminium to the construction of things for which it is particularly suited is gradually extending. There have been many materials employed, and still more suggested, for the manufacture of cocks suitable for use in chemical works and those industries in which acid and corrosive fluids have to be controlled. The field for a cock applicable to the brewing, vinegar, and similar trades has up to the present been practically a virgin one. Seeing this Messrs. Bennett, Sons, and Shears, London, have recently made an aluminium and ebonite cock upon the lines set forth in Deaville's patent. The barrel is made of aluminium, and is fitted with a vulcanised plug, and the wear and tear is very small. The use of aluminium presents a great advantage over numerous well-known alloys, as it is not of such a poisonous nature as lead, and so is especially suitable for dealing with dietetic substances.

IN a paper on "Influence of Character of Sand on Cement Mortar," by A. S. Cooper, in the J. Franklin Institute, the author describes numerous experiments he has made on the influence of sands of varying fineness and character of grain on the tensile strength of cement-mortar briquettes prepared with them. He arrives at the following conclusions:—(1) Other things being equal, a fairly coarse sand, *e.g.*, one passing through a 12 sieve—twelve wires to the inch—and caught on a 16 sieve, gives mortars of higher tensile strength than do finer sands; (2) this effect of size of grain disappears with sands fine enough to pass a 40-mesh sieve and caught on a 60-mesh sieve, sands finer than this give similar results; (3) the character of the surface of the grains is of moment. The *Journal* of the Society of Chemical Industry points out that mere sharpness of grain is not the only point to be considered, for an extremely sharp sand may have a smooth surface on each facet, and a moderately rough surface is preferable.

IN one of the reports of the Geological Survey of Norway is a communication by A. Helland on the depths of the lakes in Jotunheim and Thelemark, as ascertained from soundings by himself and others; but unfortunately all of them have been made in the line of the length of the lakes, none of them transversely, thereby missing a most important clue to the explanation of their origin. He gives longitudinal sections of four of the principal lakes in Jotunheim, but the irregularities in the bottoms are not favourable to the glacial erosion theory which he supports; transverse sections would probably prove more instructive. Of the forty-two lakes mentioned, no less than twenty-three of them have their bottoms below sea-level. The following series of figures represents the number of feet below sea-level of the first twelve, viz., 1417, 1085, 715, 712, 593, 568, 528, 456, 456, 456, 361, and 190. The first is the Hornindals Vand, the surface of which is only 177ft. above sea-level, but the bottom is 1417ft. below it; the second is the Mjösen Vand, the surface of which is 397ft. above, and bottom 1085 below sea-level. The great depth below sea-level seems to militate against the theory that they were eroded by ice.

IN a discussion on a recent paper by Mr. R. Davison, on "White Metals for Wearing Surfaces," before the Institute of Marine Engineers, Mr. James Adamson said he remembered one steamer at Glasgow, which required to have the whole of her main bearings filled up with new white metal within nine months. She had only made two round voyages before the whole shaft had to be lifted and the main bearings refilled with white metal. After the ship was lined up, she ran with the second lot of white metal for nine years, and, he believed, it was actually cheaper in price. He was acquainted with another steamer which ran for fourteen years with the same metal that she had in when she left the builders' hands, and she was running hard during all that time. Another steamer ran for eight years without her bearings requiring to be lined up, and still another ten years. He had found from experience that a hydrocarbon oil ran better with white metal bearings than ordinary engine oil, and in the case of the steamer to which he referred that ran for twelve years without her bearings having to be lined up, nothing but hydrocarbon oil was used from the time she left the builders' hands. Mr. Adamson gave an instance where white metal had been applied to worn excentric straps with good results. These straps, he said, had previously given trouble every voyage, and in one case the brass had worn down $\frac{3}{16}$ths of an inch in a six weeks' voyage. White metal was then put into them, and they had now been running for nearly four years without giving any trouble whatever. There were six of these excentric straps, and they were treated with three different kinds of white metal as an experiment. All of them had done equally well and had never given any trouble. He did not think that white metal did well, as a rule, with water, especially salt water. Mr. Wilson said he found white metal in a certain ship, and they could only run it with the best castor oil and a little water. The moment they took the water off they had trouble. That only referred to the bottom ends. The main bearings ran a little better.

MISCELLANEA.

AN inquiry has been held in Glasgow by Admiralty experts into the cause of a recent explosion on board the first-class cruiser Terrible. It was found that the paint in the bilges gave off an inflammable gas that found its way into the circulating pump chamber through the bilge connection. Some of the workmen who were passing with a naked light ignited this volatile gas, with the result that the circulating pump chamber burst so badly that a new one will have to be substituted. Fortunately the force of the explosion spent itself in the chamber.

DAMAGE to the extent of about £20,000 was done at Hull an the 15th inst. by the collapse of some old gates, used for dry dock purposes during the extension works at the fish dock. The docks are owned by the North-Eastern Railway Company. Almost all the vessels moored in St. Andrew's Dock broke away and a smack was smashed up, many other vessels being sunk or seriously damaged. There was no loss of life, though both women and children were on the sunken vessels. The collapse of the gates is said to have been due to the hidden springs being freed by pile-driving and excavations.

AN alarming explosion occurred on the 14th inst. on board the French ironclad Admiral Duperré. A loud report was heard and the after part of the vessel was soon filled with thick smoke, which was found to be issuing from the central powder magazine on the lower deck. The door of the magazine was hurled a distance of 30ft., and investigation showed that a cartridge about 13in. long had exploded, but that none of the other cartridges among which it was packed were discharged. The magazine contained 3000 kilogrammes of gunpowder and mélinite shells, none of which were disturbed in any way. The explosion is attributed to the overheating of the magazine by pipes from the boilers.

THE first platform of the great tower at Wembley Park has been opened to the public. The base of the tower covers about an acre of ground, and the platform, which has just been completed by Messrs. Heenan and Froude, the contractors, is at an elevation of 155ft. from the ground, or 400ft. above the sea level. The whole tower when completed will be 1150ft. in height. From the first platform, on a clear day, the Crystal Palace, Windsor Castle, and the grand stand on Epsom Downs can be distinguished. Access is gained by means of two lifts constructed to carry fifty-five persons each, and worked by means of steam engines undeath the base of the tower. The platform is composed of concrete on metal girders, and 2600 tons of steel have already been used in the construction of the first platform.

THE general report for 1895 of the Conservators of the river Thames has been issued as a Parliamentary Paper. It says, among other things, that in the case of farms, manufacturing premises, and private residences, from which pollution formerly passed into the streams of the Thames basin, the notices served resulted in a complete diversion of the sewage in 534 instances. The powers of the Conservators with respect to pollution from houseboats and other vessels were also carried into effect, with the result that the passage of sewage from those vessels was effectually stopped. The Conservators found that they have no power to expend their funds on works for the prevention of floods, but they will continue to carry out the works for navigation purposes in such a manner as to afford the best means of escape for the water in times of flood.

THE secretary of Lloyd's, replying to the recently published comments of the Chamber of Commerce of Plymouth on a previous statement from Lloyd's, states that the desire of Lloyd's is that "any further money that the Government can grant—for the object of saving life at sea—should be granted to the extension and improvement of lights and fog signals, rather than to the further extensions of telegraphic communication." This statement is dated April 8th, 1896. The Plymouth Chamber of Commerce, in a reply dated May 14th, asserts, according to the *Times*, that it does not object to the building of additional lighthouses where necessary, but it is at issue with Lloyd's in that "the Chamber insists on the paramount necessity that lighthouses, when built, should be utilised to the fullest extent possible for the saving of life and property by putting them into telegraphic communication with the general telegraphic system of the country."

OWING to its sheltered position, its comparative immunity from tidal disturbance, and facilities as regards depth of water at all times, the measured mile at Skelmorlie, and the stretch of firth between the Cloch and Cumbrae Lights, have become the favourite rendezvous for new steam vessels from all quarters. The fleet of high-speed Channel steamers plying between Dover and Ostend, built by the Belgian firm of Cockerill, as well as by Messrs. Denny, Dumbarton, have been tried under the same conditions on the Skelmorlie course; and the vessel presently on hand by the former company will also be sent to the Clyde for trial. Of the formidable fleet of torpedo destroyers now possessed by this country a large proportion have been put through their paces at Skelmorlie mile, not only those built on the Clyde, but those of Birkenhead and Barrow production. Two destroyers from Messrs. Laird's stocks at Birkenhead, the Quail and the Sparrowhawk, have during the past fortnight been undergoing their trials, and it is stated that during the ensuing summer and autumn as many as nine of these phenomenally speedy craft will be sent round to the Clyde from Birkenhead for trial.

THE death is announced of the editor of the *Leeds Mercury*, Mr. Herbert Stanhope Baines. Mr. Baines had been recommended by his medical adviser to take a short sea voyage; not because of any organic disease, but simply on account of some giving way of nervous force, under the pressure of work and engagements. He sailed for the Canary Islands on the 11th of last month, in Messrs. Elder, Dempster, and Co.'s steamer Accra. He arrived at Las Palmas on the 17th, and allowed himself to be tempted to proceed on the 18th to Sierra Leone, and thence further down the Gold Coast. Having changed from the Accra to the Benin for the return journey, he seems to have succumbed to the influences of that trying coast on Saturday last, the 9th inst. Mr. Herbert Baines was the second son of the late Mr. John William Baines, and his father was the second son of the late Sir Edward Baines. Born on the 5th January, 1868, he commenced his education at the Leeds Grammar School, whence he passed, in 1885, to the London University, and whence, again, after matriculation, he went on to Caius College, Cambridge. He took his B.A. degree with honours in 1889 in the Classical Tripos.

THE Corporation of Chester, as the promoters of a Bill empowering them to construct a weir or tidal dam across the Dee, appeared on the 14th inst. before the Court of Referees—Mr. J. W. Lowther presiding—to object to the *locus standi* of certain petitioners. The Great Western Railway Company, as the owners of the port of Saltney, claimed that they had a special interest, which might be injuriously affected by the stoppage of the tidal flow in the estuary. The reply of the promoters was that the interest of the company was represented by the Dee Conservancy Board, to which they appointed two of the twenty-five members. The committee granted the petitioners a general *locus standi*, and a similar position was conceded to the London and North-Western Railway Co. A *locus standi* was also granted, on the ground of special interest, to the Hawarden Embankment Trustees, the Chester Gas Company, and the owners of property below the proposed works. In the case of the United Alkali Company and the District Councils of Hawarden, Holywell, and Mold, *locus standi* was refused. In reference to the provisions of the Bill enabling the Corporation to prevent the pollution of the Dee, a limited *locus standi* was given to Flintshire County Council and Llangollen Urban District Council. The Bill will come before the Police and Sanitary Regulations Committee after Whitsuntide.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

F. K. J.—*If you will send us a short description of your invention, we shall be happy to give you our opinion in confidence as to its merits.*

J. W. C. (Bridgewater).—*You will get it from Messrs. Calvert and Co., publishers, Manchester.*

D. A. F.—*"The Steam Engine," by A. Jamieson, and "Oil and Gas Engines," by Bryan Donkin, both published by Messrs. Charles Griffin and Co. Also "Oil and Gas Engines," by W. Robinson, published by E. and F. N. Spon.*

CORRUGATED IRON.

(*To the Editor of The Engineer.*)

SIR,—We would like the names of makers of corrugated sheets, with ¼in. corrugations, and also manufacturers of machinery for stamping and punching holes in the sheets after corrugation. K. P.

Neath, South Wales, May 18th.

THE VELOX DRILLING MACHINE.

(*To the Editor of The Engineer.*)

SIR,—We want the name and address of the maker of the "Veloz" or "Velox" Drilling Machines, being unable to find out where and by whom these machines are supplied. We shall be obliged to any reader who can inform us. C. W. E.

Glasgow, May 15th.

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. *£0 14s. 6d.*
Yearly (including two double numbers) .. .. *£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate or any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
Half-yearly .. .. *£0 18s. 0d.*
Yearly .. .. *£1 16s. 0d.*
THICK PAPER COPIES—
Half-yearly .. .. *£1 0s. 3d.*
Yearly .. .. *£2 0s. 6d.*

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF JUNIOR ENGINEERS.—Saturday, May 30th, at 10.30 a.m. Visit the Fowler-Waring Cable Works, North Woolwich.

INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, May 28th, at 8 p.m. Paper: "The Utilisation of Water Power, especially with a small fall, with some examples of Plants for the Generation of Electrical Energy," by Mr. Alph Steiger.

ROYAL INSTITUTION OF GREAT BRITAIN.—Tuesday, May 26th, at 3 p.m. Lectures: "The Building and Sculpture of Western Europe," by Professor T. G. Bonney, D. Sc., LL.D., F.R.S. Thursday, May 28th.—"Lake Dwellings," by Mr. Robert Munro, M.D., M.A. Friday, May 29th, at 9 p.m. Discourse: "John Wesley: Some Aspects of the Eighteenth Century," by Mr. Augustine Birrell, Q.C., M.P. Saturday, May 30th, at 3 p.m. Lecture: "The Moral and Religious Literature of Ancient Egypt," by Dr. E. A. Wallis Budge, M.A., Litt. D., F.S.A.

"THE ENGINEER"
HORSELESS CARRIAGE COMPETITION.

WE have recently received suggestions from many quarters that it would be expedient that our Competition should be postponed until the spring of next year, for the reason that the date already fixed does not allow sufficient time to competitors to produce really satisfactory vehicles for trial, and, further, that until the Bill now pending in Parliament has been passed, designers cannot be quite sure that they are working on the right lines. So far as we are concerned, we are perfectly ready and willing to abide strictly by the conditions which we have already published, but we shall be glad to have the views of those who are interested, so that we may decide upon a course which will lead to the best results for all.

THE ENGINEER.

MAY 22, 1896.

THE PROBLEM OF SPEED.

WE print on another page a very interesting and instructive article by M. Normand, of Havre, upon the problem of speed. Taking as his text that remarkable little vessel the Forban, which, by attaining a speed of 31·029 knots on her official trial last year, won for herself the much-coveted title of the fastest vessel in the world, M. Normand traces the process of evolution of speed through a long series of torpedo boats built by him, and by examining the laws which have governed progress in the past he endeavours to forecast the line of advance in the future. M. Normand deals only with his own vessels, because, as he says, it is only concerning these that he has exact information. It is noteworthy that the speeds of his torpedo vessels at the beginning of the series fall far below those which were being obtained in this country at the same time. For example, his list begins with the Balny, built in 1886, and having a speed of 19·525 knots. Mr. Yarrow, in the preceding year, had achieved 25·1 knots. Again, in 1889 the speed of the Avant-garde was only 20·975; but two years before this Messrs. Thornycroft's Ariete had attained 26 knots. In April last year H.M.S. Boxer, by the same builders, had the lead with 29·314 knots; but she was soon beaten by the Sokol, built by Mr. Yarrow, which made 29·77 knots on official trial. The Sokol had held the proud position for a few weeks only when the Forban came with a rush to the front, and put up the record by 1¼ knots. Even her speed has been since surpassed by Messrs. Thornycroft with the Desperate, which now claims first place with a speed of 31·034 knots; but it is only fair to say it was not attained on an official trial, but when the vessel was at a light draught of water.

A study of M. Normand's series makes it abundantly evident that the governing factors in speed evolution have been the assignment of an ever-increasing fraction of the displacement to the propelling machinery, and an enormous increase in the amount of power which has been got out of a ton weight of engines and boilers. Thus in the Balny one-third of the displacement is devoted to propelling machinery, but in the Forban the fraction is increased to one-half. Again, in 1889, a horse-power was obtained for a weight of 72·7 lb., but M. Normand has now succeeded in reducing this to 35·3 lb. This is a very remarkable achievement, and one which should cause our own builders to look to their laurels. That such a low weight per I.H.P. should be accompanied by a comparatively low speed of revolution is very creditable. The revolutions of the Sokol were as many as 420 per minute, while in the Forban they did not exceed 365. Another point upon which M. Normand is to be congratulated is the very low consumption of coal both at full speed and at moderate speed. Such figures as 1·54 lb. per I.H.P. at full speed and 1·1 lb. at low speed will almost excite incredulity in this country; but there is no doubt that M. Normand, by paying the greatest attention to the steam economy of his engine, has attained to a very high degree of perfection, and to his economical engine is due in no small degree the success of the Forban, for not only is he able greatly to reduce the heating surface of his boilers as compared with what would be required with a more wasteful engine, but from the conditions of contract, according to which the quantity of coal to be carried on trial is determined by the amount necessary to give the vessel a certain radius of action, any improvement in economy reduces the load to be carried.

M. Normand appears to think that the greatest opportunity for obtaining a still further increase of speed will be found in effecting a considerable reduction in the volume of the vessel above water. He assumes that the displacement of the Forban could be increased from 127 tons to 190 tons, by immersing her more deeply in the water, the lines being appropriately modified, but the total depth of the vessel remaining unchanged. To get rid of the inconvenience of such a low freeboard as would then remain, he proposes to fit a flying deck upon which all the work of the ship could be done, and under which the sea could freely pass. After allowing weight for this deck, for some extra coal to give the same radius of action as at present, and for some strengthening to the hull, he estimates that there would remain an available weight of about 54 tons to add to the machinery, and that this would result in an increase of four knots in speed. Even if it be granted that sufficient range of stability could be secured under such conditions, is M. Normand right in assuming, as he does, that the value of the coefficient $\frac{V^3 D^{\frac{2}{3}}}{\text{I.H.P.}}$ would remain unimpaired? It seems to us very doubtful.

There are some other points in the paper to which we think exception might be taken. M. Normand ascribes the improvement which takes place in the performance of a small vessel after a certain critical speed has been passed, to a rising of the hull out of the water. Now there is no doubt that vessels of suitable form, driven at very high speed, can be made to lift, and more or less to skim on the surface, but is there any evidence that torpedo vessels do so? It would seem as if a necessary condition of a reduction of displacement—which is, of course, a consequence of any lifting action—is that water should be driven downwards by the vessel, and this downward velocity must continue until the vessel has passed. Then the reaction of this vertically moving water would serve to support so much of the weight of the vessel as was in excess of the displacement. To secure this condition the vertical longitudinal section of the vessel must continuously descend from forward to aft, or, in other words, the buttock lines should have their lowest points at the extreme stern, terminating there in an abrupt corner. The buttock lines of torpedo boats rise from amidships to the stern, and the water is probably rising too, after the midship section has passed, and if this is so it can have no vertical reaction such as we have described to assist in supporting the weight. A ricochetting shot rises out of the water because it imparts a downward velocity to a large quantity of water struck by it, and the equivalent of the energy required to change the direction of the shot is to be found in the downward momentum of the stricken water. It is true a round shot may be considered to be a vessel with buttock lines rising from the midship section to the stern, and does not, apparently, fulfil the conditions prescribed; but the velocity of the shot is so great that a trench is ploughed in the water, which does not close up immediately behind the shot, and we are far from having attained this speed in torpedo boats. We thought it was now generally accepted that the improvement in performance referred to was due to the subsidence of the wave-making element of resistance at a critical speed, which, in vessels of similar form, is proportional to the square root of the length.

A GREAT WELSH WATER SCHEME.

THE London County Council, in proceeding with Mr. Binnie's Welsh water scheme, is threatened with more than a sentimental opposition by the South Wales counties whose watersheds it was proposed to tap for the storage reservoir at Llangorse. When discussing, a few months since, the cry of "Welsh water for the Welsh," then being raised in the Principality, we referred to a proposal, originating with the late Lord Swansea, that the counties concerned should unite in forming a Water Authority to preserve the water sources for home consumption, or at least to safeguard them from outside attack. That proposal now appears to have taken practical form in more ways than one. The Glamorganshire County Council has formulated a plan to combine all the health authorities within its borders, together with portions of the counties of Monmouth, Brecon, Carmarthen, and Cardigan. These would constitute the Water Authority Lord Swansea suggested, and it is in contemplation that the new Board should, in due course, seek powers to secure and conserve the watersheds within its area for the future supply of a population which, it is claimed, is increasing by leaps and bounds year after year. To this end the services were enlisted of Mr. J. A. B. Williams, M. Inst. C.E., the designer of the Breconshire reservoirs of the Cardiff Corporation, and Mr. R. E. Middleton, M. Inst. C.E., and between them these gentlemen have devised a project which in its first stage would cost £1,315,000, and in its completion a sum roughly estimated at ten millions sterling. The first stage is the construction of a storage reservoir near Trecastle, on the north border of Carmarthenshire, and the head waters of the Usk. The reservoir would contain 4,538,000,000 gallons, yielding a daily supply of 12,000,000 gallons, to be distributed to surface reservoirs in different districts as may be arranged. At an additional cost of £300,000 for a second line of pipes, the daily supply could be increased to 23,000,000 gallons.

It may be objected that this is a comparatively small quantity for division, even as a supplementary supply, over the wide area represented by the Water Authority, and for a population which, according to Mr. Williams' forecast, will have increased from 802,000 to 7,782,401 in a hundred years' time. This criticism has been anticipated by the engineers. Their scheme comprises ultimately the reservation of the Irfon and the Towy, and the construction of fifteen reservoirs in those water areas for storage and compensation purposes. Altogether they would annex a gathering ground of 122 square miles—18 square miles on the Irfon, 43 square miles on the Towy, and 61 square miles on the Usk. The estimated yield is 44,000,000 gallons from the Irfon, 20,000,000 gallons from the Towy, and 51,000,000 gallons from the Usk. From these sources it is reckoned that a daily supply of 115,000,000 gallons could be obtained. Even this would not be sufficient, on Mr. Williams' figures, to cope with the growing demands of the population as another century rolls in upon us. On present data he sets down the deficiency in 1995 at 131,674,000 gallons. With the 115,000,000 to be drawn from the three valleys named, there would yet remain a daily deficiency of nearly 17,000,000 gallons a hundred years hence. Of course that would be an argument for an extension of the works still further afield, the available watershed, presumably, being pre-empted meanwhile, and notices issued "Trespassers Beware." The point of immediate interest, however, is that the project of Messrs. Williams and Middleton strikes at a vital point of Mr. Binnie's plan. The Usk is his chief source of supply for the Llangorse reservoir, with its storage capacity of thirty-eight thousand million gallons. The Irfon came next, and the Towy was not an inconsiderable factor in his estimate. By damming the Usk Mr. Binnie calculated on a supply of 182,000,000 gallons per diem, and from the Irfon 135,000,000 gallons. Obviously, therefore, the joint-county scheme in South Wales is of intimate concern to the London County Council and to metropolitan consumers.

SANITARY CONDITIONS AT HONG KONG.

It is understood to be a moot point as to whether the prevalence of bubonic plague at Hong Kong is to be attributed to local sanitary conditions or to its introduction from the adjacent mainland. It is certainly the case that there have been and are many instances of the visitation in Canton and other large Chinese centres, but we believe the authorities of these trace—or pretend to trace—its introduction among them by natives returning from the British island. But whether this last claim be or be not correct, it is certain that the condition of our most Eastern possession has long been known to be favourable to the propagation of this class of disease. As far back as 1889 the drainage of the chief settlement there was a matter of anxious consideration by the local government, and in our issue of May 3rd of that year was discussed the proposals put forward for perfecting, or at least amending, this. As we then stated, the difficulties to be overcome were great and singular. Differences of race among the inhabitants, varying tastes as to locality of residence, and local configuration, all combined to render the problem of efficient drainage one particularly hard to solve. How far the propositions towards that end then made have been carried out we are not aware. But the danger that must attend delay in the adoption of remedial measures was at that time fully recognised, and we have no doubt that to some extent, at least, the drainage of this settlement has, since we last addressed ourselves to the subject, been materially improved. It is, therefore, natural to feel surprise that an outbreak of the kind lately suffered from should, for the first time, we believe, in the history of the Colony, have made its appearance. But medical opinion seems to be divided upon the point as to whether the particular form which this disease has taken can be attributable to defective drainage. Upon the medical aspect of the case we can offer no opinion; but we do know that the Great Plague that devastated London in 1666 was of the same bubonic type as that we are now discussing; and that old-time experience warrants the belief that, even if the outbreak then occurring had not its immediate origin in the then state of London, it was fostered and developed by it. And this would seem to have been the case with the more modern example in Hong Kong. The Governor, Sir William Robinson, on the first appearance of the disease, took most energetic measures to combat it. In our article above referred to we made particular reference to the predilection of the Chinamen for having their houses huddled together in hollows, into which it was almost impossible for the wind to penetrate. We referred to this fact as presenting, perhaps, even greater obstacles to perfect sanitation than did even the drainage difficulties. The Governor and the other local authorities appear from the first to have coincided with us in this opinion, and free use was made of the axe and of even more speedy methods for destruction among these rookeries. That, at all events, the evil had been largely fostered in these was apparent from the results obtained by the adoption of this course. The disease showed immediate abatement, and would probably have disappeared altogether had economic conditions and the provision for housing dispossessed residents admitted of the clearance being made as complete as was desirable. As it is, the disease still lingers in the Colony, and the numbers attacked seem to fluctuate considerably day by day and week by week. We do not ourselves think that the outbreak is to be attributed to inefficient drainage. Although, as we have said, we are ignorant of the extent to which improvement has been effected in this since we discussed the subject in 1889, we have good reason to believe that the then existing state of things has been materially ameliorated. This cause can, therefore, hardly be assigned for the outbreak, and still less for its fluctuating continuance. We believe it has ever been recognised that all the outbreaks of plague in Europe have been introduced from the East. Indeed, we believe it is acknowledged that this form of disease, that of which the bubo is the chief external development, is ever present among Eastern native communities. It needs but some stimulating conditions to present themselves to invite its speedy covering of large continents. That in this case of Hong Kong it has not travelled far beyond the island itself, seems to point to the existence of local conditions specially favourable to its existence. For the reasons we have named, we do not think that this condition can be attributable to defective drainage. The primary cause, there can be little doubt, was the herding together of people whose domestic habits are particularly uncleanly, in quarters to which the wind had little chance of access. To destroy the germs of the disease, and wholly to extirpate it, these quarters of residence must be not merely thinned but almost wholly destroyed. An instance occurs to our memory of an experience illustrating the results that might be expected to attend such an operation. An outbreak of cholera occurred among the Malay soldiers at an Eastern station. The lines in which these men were housed were in successive rows almost athwart the course of the prevailing winds. These rows were relatively so close to each other that they induced draughts, to which the soldiers were exposed at every exit from their heated huts. The cases multiplied with such rapidity that the commandant applied to the engineer in charge of the local public works, the telegraph to headquarters not having at that date been constructed. On his own responsibility that officer utterly demolished every alternate row of the lines, sweeping them utterly away in the course of a single day and night—of course, burning every stick and leaf obtained from them. Within two days of this drastic measure being adopted the disease was checked, and within a week there was an entire cessation of fresh cases being reported.

Some such course as this would seem to be desirable in the case of Hong Kong. It is, we believe, at present a local disease, fostered entirely by local conditions. If it be not so, how is it that with the stream of Chinese ever proceeding between Hong Kong and the Straits Settlements, these last have presented no instances of the plague? We fear that consideration for the island revenue may operate towards making its authorities hesitate in taking steps as thorough and as full as those we suggest. If so, the case must be one in which Imperial help should be given. For so long as the Chinese residents are permitted to live in hollows without ventilation, and on a soil that must be largely composed of the detritus from granitic rocks, so long may we be assured that Hong Kong will remain the centre from which the plague may at any time take its departure to ravage throughout not only the East, but even, possibly, the far distant West. While we here in England may be better guarded than heretofore against its incursion, and may perhaps disregard the possible danger to ourselves, it should never remain open to be said that any spot under British administration should continue a possible plague centre. If the difficulty is, as we apprehend it to be, too serious to be fully met from local revenue, then let it be, as we have suggested, a case for help from Imperial funds.

◆◆◆

THE BISCAY AND MEDITERRANEAN CANAL.

The project of uniting the Bay of Biscay with the Mediterranean by means of a canal capable of accommodating large sea-going vessels has again met with condemnation at the hands of the Commission appointed by the French Government to investigate the matter. For many years the idea has attracted a good deal of attention, not only from the commercial advantages which would arise from a shortened length of voyage between the ports of Northern Europe and the Mediterranean, but also to a large extent from the desire to provide a means of naval communication for the French fleet in time of war, without being compelled to pass under the guns of Gibraltar. In The Engineer of November 9th, 1894, we gave some particulars of the various schemes which had been proposed for the construction of such a canal, and then expressed the opinion that it seemed to be a waste of time and money to make further investigation into their feasibility. The engineering features present no special difficulty; there is no doubt about the possibility of making such a canal, but it would be at such a cost as to make the investment distinctly unprofitable. The promoters of the present scheme have had the benefit of the fullest publicity and criticism. Premiums amounting to £4000 were offered for competitive designs, and an exhibition of the various plans was held in Paris in June, 1894. Various ideas of a more or less original nature, including ship railways and rolling docks propelled by electricity, had their respective advocates. The several schemes finally selected indicated a canal of a length varying from 220 to 320 miles, of a size sufficiently large to admit of navigation by the largest armour-plated warships, and at a cost estimated at £40,000,000 to £60,000,000. After repeated pressure the French Government, towards the end of last year, consented to appoint a Commission of engineering and commercial experts to inquire into the practicability of the idea, and their report has just been issued. From the financial point of view the Commissioners cannot see that there is any probability of a large enough traffic being attracted to the new canal to make it a profitable investment. Then the shortening of the distance between the ports of Northern Europe and the Mediterranean would be largely discounted by the slow speed necessitated in navigating a canal where the waterway would be restricted and the locks numerous, so much so that little time would be gained by the new route. Objection is also raised to the danger of floods along certain sections of the canal which it was proposed to construct in raised embankments. The Commissioners unanimously condemn the project as one which it is inadvisable to attempt to carry out. After the thorough investigation which the various schemes of the last twenty years have received, it is probable that this is the last that will be heard of the idea for some time to come.

SILK FROM WOOD.

We have recently had an opportunity of inspecting a number of specimens of artificial silken materials which have been produced by a novel process from wood pulp. The process now extensively employed in a works erected at Besançon, in France, is briefly as follows:—Wood in the form of cardboard is treated with a solution of nitric and sulphuric acids until it forms a pulpy mass, after which the acids are expelled by hydraulic pressure, and the mass is then thoroughly washed in water vats. It is next partially dried before being treated for some hours in a revolving cylinder containing alcohol and ether. After this the mass is passed through a filter, which it leaves resembling thick gum, and is run into cylinders, whence it is forced by pneumatic pressure into pipes into the spinning department. The spinning machinery is served with a common pipe, from which the gummy material is forced through small taps arranged close together, each tap having a glass tube or nozzle of exceedingly minute bore. We are informed that the combined diameters of ten of these tubes are only equal to the thickness of a human hair. The effect of the pneumatic pressure is to force the pulp through the nozzles in an almost invisible filament, and according to the thickness of thread required so is the number of these filaments regulated. By the pressure of the fingers they are made to adhere in the form of a thread, and are passed through guides on to bobbins. Before the silk thus produced can be employed in spinning, it has to be denitrified to render it uninflammable—an operation necessary owing to the chemical treatment which it underwent in the early stages of its production. It has also to be placed in the form of hanks on two revolving rollers, to stretch and roll it, giving to the material a very high gloss. Although the artificial silk is said to take dye much more readily than natural silk, it is not quite so strong, having only about 80 per cent. of the tenacity of the latter. We are informed that a company is in course of formation with a view;) work this process in this country, and that a mill is tob) erected in the neighbourhood of Manchester at a cost) £30,000, for the manufacture of silk yarn from wood pulp for sale to weavers, who will, it is expected, work it up by means of their existing machinery. As the artificial material is said to cost only about one-fourth that of the natural silk, the experiment will be watched with some interest.

COMPLICATIONS IN THE COAL TRADE.

In all probability no such important complications have occurred in the history of the English coal trade as now confront coalowners and those who hold the responsible position of advising the men. On the one hand a gigantic amalgamation in the Durham coal trade has sprung into existence by which one firm will become the sole owners of twenty-seven of the most important collieries in the county capable of producing four and a-half million tons of coal per annum, whilst the Conciliation Board, which has regulated wages in the same county, is likely to be dissolved early in August. As is well known, a third and probably a more serious complication than either of the two mentioned, awaits solution by the combination or otherwise of the Conciliation Board connected with the federated area. The position of the English coal trade, it will be seen, is crucial, inasmuch as the crisis which affects the Durham and Northumberland coalfields may be said to be represented by the Miners' National Union, whilst the dead-lock which exists in respect of the Conciliation Board arrangement, which of late years has governed the federated area, is represented by the Miners' Federation of Great Britain. What course will be adopted time only will reveal. The three important complications referred to as occurring almost at one and the same time are sorely perplexing to all interested in the coal trade. The complications are all the more harassing, on account of their occurrence at one of the most critical periods of the year, when a number of important coal contracts are in the market, and railway companies and other large consumers of coal are asking for renewals which will insure them supplies of locomotive and other fuel from the 1st of July next. In addition to tendering, as it were, blindfolded, the coalowners have to face a large and excessive output of coal at a time when prices in the open market are favourable to purchasers. As an example of the critical position of affairs, it may be stated that the Midland Railway Company, which is a large consumer of locomotive and other coal, has had its tenders on hand more than a week, and, doubtless having an eye to the situation, is only asking for supplies for three, six, and nine months. A meeting of South Yorkshire coalowners was held on Tuesday to consider the situation. As is usually the case, the price at which tenders were to be sent in has not been stated, but sufficient has leaked out to show that a price in advance of the North-Eastern current contract, viz., 7s. per ton of 20 cwt., has been asked, but it does not follow that it will be sustained. Of late the best South Yorkshire hards have been procurable in the open market at rates lower than those contracted for, but in face of the great uncertainty which exists it is held that so valuable a quality of coal as is demanded for export and railway purposes ought not to be sold at reduced rates. In the face, however, of the fact that a large number of new collieries on an extensive scale are being opened out and developed in the great Midland coalfield, extending from Leeds to Nottingham, it is difficult to see how the law of supply and demand can be set aside either by combination or the most skilful arrangements for putting an artificial value on coal.

EXPLOSION ON A FRENCH IRONCLAD.

An explosion is reported as having occurred on board the French ironclad Amiral Duperre last week. As far as can be made out from the telegram, a small cartridge, 13in. long, exploded in a "magazine containing," so says the telegram, "3000 kilo*metres* of gunpowder and melinite shells." None of the other cartridges were exploded. If this account is substantiated, it is a strong argument in favour of those who assert that no danger of wholesale explosion is to be anticipated from a single shell being exploded from any cause in a turret containing a store of loaded ammunition. This point has been one over which much contention has raged, as not a few persons in authority consider it exceedingly dangerous to have charged shell stored in any place which may be entered by an enemy's shot. Danger from the fuses is almost out of the question, as they should not come into action until struck twice, the first to release the hammer, the second blow to cause it to strike the detonating powder. If the violence of explosion, which was sufficient to blow the door of a magazine "30ft." was not able to cause the ignition of a number of cartridges in close proximity to the one fired, the danger of a disastrous explosion from a similar cause in action seems considerably minimised.

LITERATURE.

The Electrical Transmission of Energy. By Arthur Vaughan Abbott, C.E. New York: D. Van Nostrand Co. London: Sampson Low, Marston, and Co., Ltd. 1895.

The author is an American electrician of repute, and addresses his preface from Chicago. He states that he has been personally indebted to many authors for his knowledge of the subjects of which the book treats, and that having passed it through the sieve of practical experience, he now writes from his own standpoint. It is a volume of considerable size, containing nearly 600 pages, and provided with a number of folded sheets of statistical diagrams at the end.

After referring to the elements of the subject, he deals with the properties of wire, and gives useful comparative tables of wire gauges, and a short account of the manufacture of wire. Referring to the abrasion caused by the branches of trees swaying against insulated overhead wires, he states that a coating of bamboo has been found an efficient preventive. Ordinary fishing poles are sawn longitudinally, the knots are cut out with a gouge, and the bamboo is then lashed to the wire. After describing the methods of testing insulation resistance, he says, "While 100 megohms per mile is a very common requirement, it is impossible . . . to give a definite standard." A comparison of this with the 2500 megohms per mile now demanded by the St. Pancras Vestry for house supply at 220 volts serves to explain why electric installation is carried out more cheaply in the States than here. Again, he says, "In this country it is not uncommon to use wire in a single rod up to ½in. diameter." Although a number of tables of insulated wires are given, there is no mention of the insulation resistance of the different makes, and the author states that they are sold solely by weight. This strikes an Englishman as a rather strange system. Most of the wires seem to be merely braided, without any coat of india-rubber whatever, and the plan most usually adopted is to use a number of single insulated wires in parallel to avoid the extra cost of stranded cable.

Dealing with aërial conductors, the author gives both American and British specifications for wire, including that of the G.P.O. A useful table of sags and tensions to be observed in erecting wires is given, and the factor of safety is assumed at from four to five. Such circuits are provided with 35 to 42 poles per mile in the country, 40 to 50 poles in cities, and 45 to 55 poles in electric railway work. No process of pole preservation is employed, but he considers the process known as vulcanising good, that is, baking the poles in a closed vessel at 500 deg. Fah., thus coagulating the albumen. The best method of staying is with the Y guy, one guy branching into two parts connected to the top of the pole, and also to a point below the lowest cross arm. The author gives much valuable information on the subject of anchor poles and the strength of guy rods. In the States glass insulators are almost universally used, as their transparency prevents the formation of cocoons under the bells. A test upon a telegraph line from New York to Boston gave an insulation resistance of 6000 megohms per mile. The McIntire splice appears to be very largely used; this consists of two copper tubes drawn side by side out of the same piece of copper; the ends of the opposite wires are entered, and the whole is twisted, making a perfect joint without soldering, and giving 66 per cent. of the strength of the solid wire. As a device to obviate humming, the author's experience leads him to recommend wrapping the line wire with india-rubber, and then with lead, and fixing the wire to the insulator with a second wire treated in the same manner.

Dealing with electric railways, the author points out that the leakage of return current from the rails is a great source of annoyance; owing to the derangement of telegraphs and telephones and corrosion of pipes, the rails are now being aided by copper returns, and we believe that complete metallic circuits will be used in the near future. The author considers that no dependence should be placed on the earth circuit, and that the losses due to the circuit should not exceed 3 to 5 per cent.

A good deal of space is devoted to the subject of rail-bonding; but, in our opinion, the electric welding process, or the process by which the ends of the rails are cast solidly together, will be found preferable, and the latter process is the cheaper of the two. The author appears to favour the use of bonds, electrically welded on; but these, we know, have been found to snap in the winter and cause trouble. Iron poles are largely used for railway lines, but their use is attended with some danger owing to leaky span wires. Treating of underground circuits, he refers to the Valentine wooden conduit as being the simplest and cheapest of all; but it is no use for lead-covered cables, owing to the destructive action of the acids produced by the decay of the wood. He favours the use of light iron pipes, cement-lined, and laid in concrete, and then connected to manholes. The separate duct system of terra-cotta pipes, used largely in the States, appears to us to have very great advantages for a drawing-in system. The Brooks oil insulator system has, it is stated, not been found satisfactory. He considers that in the Callender solid system it is neither necessary to put any insulation on the copper, nor to use the cast iron boxes. The Johnson system he considers good, but far too expensive.

Chapter V. deals with electrical instruments for testing; the Boyer speed recorder is recommended for car tests, and useful tables of the specific resistance of insulating materials are given. Dealing with electric heating he says, "Car heaters operated by coal cost from 15·00 dols. to 25·00 dols., with an installation expense of 1·50 dols. With fuel at 4·50 dols. per ton, and labour 1·50 dols. per day, the cost of operating coal car heaters is about 16 cents per day of twenty-four hours. Per contra, electric heaters cost from 35·00 dols. to 40·00 dols., and the expense for current amounts to from 30 to 40 cents per day in moderate weather, and from 60 to 80 cents per day in the coldest weather." These figures are based on fuel at 3·00 dols. per ton at the generating station.

In Chapter IX., speaking of the three-wire system of distribution, the author says, "So far attempts to make incandescent lamps of much more than 200 ohms resistance have not been commercially successful; and for the standard 16-candle-power lamp, an available difference of pressure at the lamp terminals of about 100 volts is all that can be rendered useful." This statement hardly agrees with British practice at Bradford and St. Pancras. The subject of the design and proper proportion of feeders and distribution circuits is fully dealt with, and the usual practice in the States is well described.

At the end of the book he says of gas engines:—"If the gas costs 1·00 dol. per 1000 cubic feet, the cost of producing electrical energy may be estimated at 7 to 10 cents per kilowatt-hour for small engines under 10-horse power, and from 3 to 5 cents for engines of 50-horse power and over." We can heartily recommend the work as an interesting review of United States practice. The author is evidently a thoroughly practical man, and though some of the methods described may not commend themselves to British engineers for work in this country, it is always valuable to see how difficulties are surmounted elsewhere.

An Elementary Treatise on the Calculus for Engineering Students. By JOHN GRAHAM, B.A., B.E., Demonstrator and Instructor in Mathematics in the City and Guilds of London Technical College, Finsbury. London: E. and F. N. Spon. 1896.

THIS book is very well adapted for the service for which it is designed, as it provides a clear and interesting introduction of the subject, which an engineer now-a-days, especially of Electricity, cannot afford to neglect.

The author is indebted to Professor Perry for many good practical illustrations of the use of the calculus as required in familiar problems of mechanical and electrical engineering, such as the determination of the strongest and of the stiffest beam which can be cut out of a cylindrical log; the proper design of a cable of minimum cost when the power wasted is balanced by the interest, prime cost, depreciation, and repairs; the best way of arranging the cells of a battery, and so forth. The author has done well to introduce the integral calculus at an early stage, as it is now considered in authoritative circles that the notion of integration is more familiar and easier grasped than that of differentiation. We cannot perceive the rate of growth of a tree, for instance, except by noticing its integrated growth at the end of ten or twenty years. Again, any continuous function can be integrated, but it is not every function which can be differentiated. Thus, if we take very small steps alternately parallel to the two sides of a triangle, in proceeding along the third side we make a figure indistinguishable in shape and area from the rectilineal triangle; but in describing the third side we have made it equal in length to the other two sides, contrary to the theorem of Euclid. We have now a path or line which cannot be differentiated, as the analytical thumb, passed along this apparently straight edge, feels the rugosities; just as the thumb of a skilled mechanic will detect the difference between a surface according as it has been planed or milled. In an analogous manner, the surface found on a body turned in a lathe by the slide rest will, analytically speaking, be differentiable in the circumferential, but not in the longitudinal direction. Chapter XX. is a useful little chapter on Fourier's Series, which bears the marks of Professor Perry's inspiration. The author does well in such an elementary treatise to steer clear of the analytical refinements concerning uniform convergence in the neighbourhood of a discontinuity. Following Professor Perry, he trusts more to graphical demonstrations, and it is a pity that this most convincing method is so completely ignored in the advanced treatment by mathematicians. The ordinary part of Differential Equations, as much as is required for most applications, given here in a condensed form, enables the author to wind up with a complete solution of a number of useful mechanical and electrical problems.

The Number Concept: its Origin and Development. By LEVI LEONARD CONANT, Ph.D. New York: Macmillan and Co. 1896. 8s. 6d.

THIS book is addressed to the psychologist and grammarian, and not to the arithmetician. The author traces the gradual evolution of language as required for expressing higher and higher numbers, and he has made a very valuable collection of the numerals in use among savage tribes, pointing out whereabouts the word "innumerable" first occurs. He gives the familiar story of the crow who could count up to five, after which came the innumerable, and thence the fatal *dénouement* to the crow. But even with human beings the difficulty of keeping count can be easily increased, as we notice with the balls which a juggler keeps moving in the air and with other familiar tricks; and it is not very long ago that a great statesman deplored in a speech the "innumerable votes of censure of the other party." In reality, too, even the most complex of modern languages fails in numeration when it is required to record the large number expressing astronomical results, and the new index method must be resorted to.

The author traces very clearly the origin of our denary numeration in the primitive mode of counting on the fingers; if man had been born with twelve fingers and toes, instead of ten, we should have had the duodecimal scale, which possesses great advantages in the eyes of its advocates, but is not likely at this stage to prevail.

SHORT NOTICES.

Sheffield Smoke Abatement Association. Report by Mr. R. Heber Radford, as to the Stoking Competition, held March, 1896. Sheffield: Sir W. E. Leng and Co. 1896.—This pamphlet gives the results of experiments made in connection with the offer of competitive prizes to engine tenters and firemen. The experiments took place at Messrs. Davy Brothers' Works, Sheffield, and extended over five days in March last. Five competitors entered, and the experiments showed that Lancashire boilers can be fired by hand with clean small coal, so that no dense smoke need ever issue, and without any considerable amount of smoke at any time.

The Hotels of Switzerland: A Tourists' Guide. The Basle Association of Swiss Hotel Proprietors and Managers. Price 50 centimes.—This book contains a list of public inquiry offices in Switzerland, a map, about twenty pages of remarks on questions daily recurring during travel, and a list of about 145 pages of the hotels, giving brief particulars of and prices at all of them, and an illustration from photographs of each. The book is published at the Central Office of the Association of Swiss Hotel Proprietors at Basle.

Bicycling for Ladies, by Miss F. J. Erskine. London: Iliffe and Son, Price 1s.—This is a book which may be recommended as written by a rider for the information of riders and learners. The instructions are so written that they may be understood as read, and any reader will be interested in them, whatever preference may be felt as to machine or attachments. It is a book that is not written in the interests of a cycle but of cycling.

Notes on Motor Carriages, with Hints for Purchasers and Users, by John Henry Knight, with illustrations. London: Hazell, Watson and Viney, Limited, 1896. Price 1s.—The very general interest now displayed in horseless carriages will cause many people to look for some enlightenment on the new vehicle. These notes in Mr. Knight's little book will satisfy the requirements of many readers and afford an introduction to a more extensive study of the subject. The book contains eighty-four pages of small size, in which a glance is given of the history, followed by a chapter explaining the working, of an oil engine, some chapters on modern motor carriages, motor carriage contests and hints to purchasers.

Duncan's Manual of British, Foreign, and Colonial Tramway, Omnibus and Electric Railway Companies, containing abstracts of accounts, Directory of Directors, &c., &c., 1896. Nineteenth edition. London: T. J. Whiting and Sons, Ld., price 3s. 6d.—The nineteenth edition of a properly revised annual calls for few remarks, but it may be noted that the slow but apparently certain growth of public interest in mechanically propelled tramcars and modern improvements making mechanical methods a commercial success, will increase the numbers of people who will be glad to turn to this manual. The time has come when on many lines in this country, which with horse haulage cannot possibly pay, mechanical propulsion, which is increasingly successful on the Continent and in America, must be adopted, and the facts and figures given n this manual are especially valuable just now in this connection.

BOOKS RECEIVED.

Computation Rules and Logarithms: With Tables of Other Useful Functions. By Silas W. Holman. London: Macmillan and Co. 1896. Price 5s. net.

Graphical Calculus. By Arthur H. Barker, B.A., B.Sc. With an introduction by John Goodman, A.M.I.C.E. London: Longmans, Green, and Co. 1896. Price 4s. 6d.

Water Supply. Considered Principally from a Sanitary Standpoint. By William P. Mason. First Edition, First Thousand. New York: John Wiley and Sons. London: Chapman and Hall, Ld. 1896. Price 21s. net.

Summer Tours in Scotland: Glasgow to the Highlands. The Royal Route, with Time Tables and List of Fares, by David MacBrayne's Royal Mail Steamers, Columba, Iona. &c. Official Guide. New Edition. Glasgow: David MacBrayne, 119, Hope-street. Price 6d.

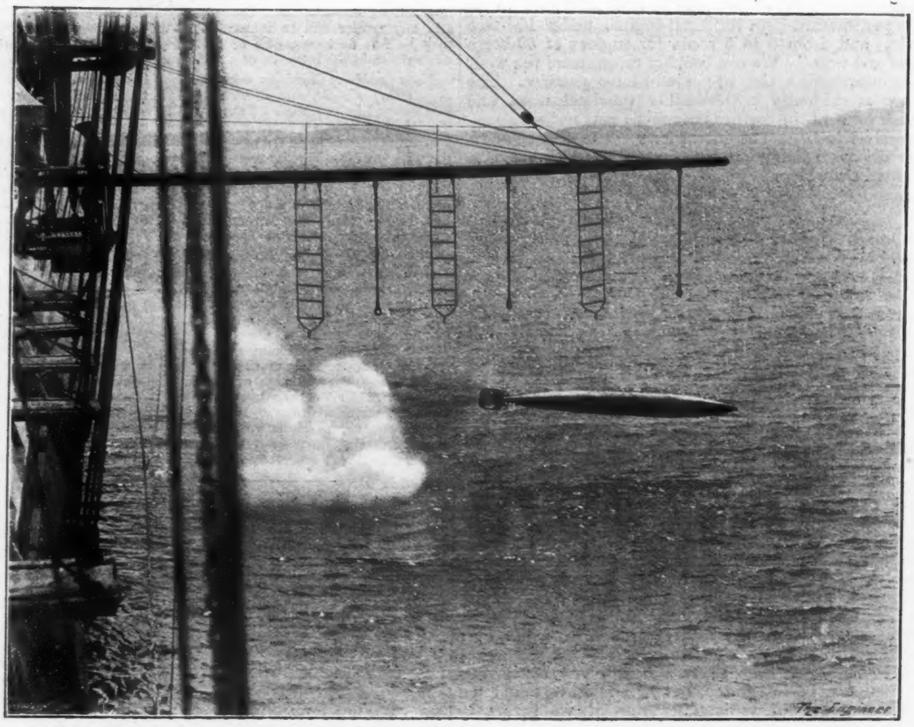
Modern Opera Houses and Theatres. Examples Selected from Playhouses Recently Erected in Europe. With Descriptive Text, a Treatise on Theatre Planning and Construction, and Supplements on Stage Machinery, Theatre Fires, and Protective Legislation. By Edwin O. Sachs, Architect, and Ernest A. E. Woodrow, A.R.I.B.A. Volume I. With 100 plates and 93 illustrations in the text. London: B. T. Batsford, 1896.

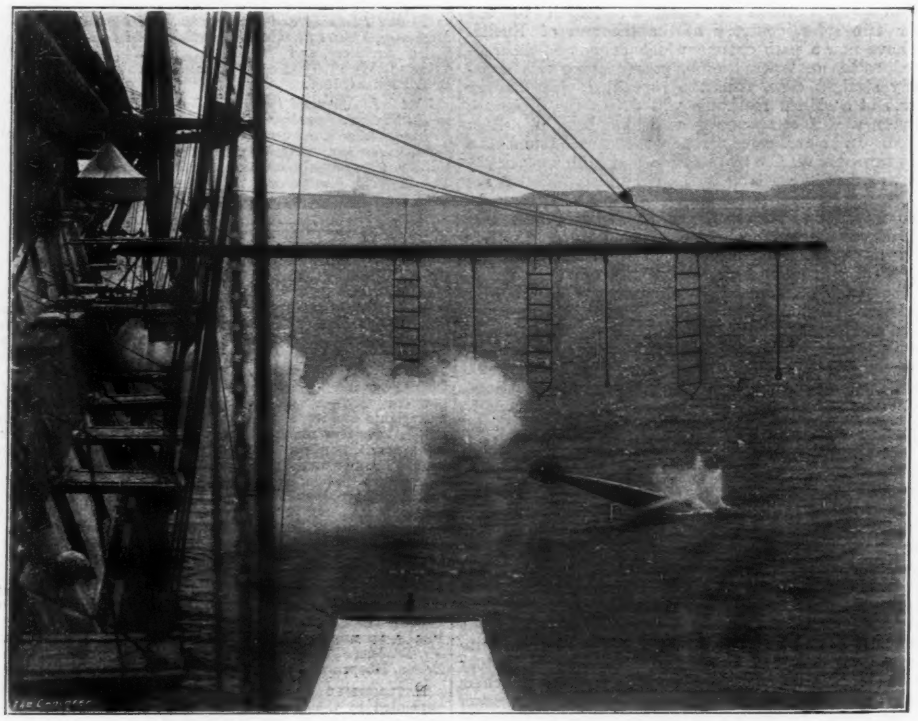
Electric Lighting and Power Distribution. An elementary manual on Electrical Engineering, suitable for students preparing for the preliminary and ordinary grade examinations of the City and Guilds of London Institute. By W. Perren Maycock, M.I.E.E. Third Edition. Thoroughly revised and enlarged. In two volumes. Vol. I. 231 illustrations, index, and ruled pages for notes. London: Whittaker and Co. 1896. Price 6s.

TRADE AND BUSINESS ANNOUNCEMENTS.—The business of Messrs. Conrad Knap and Co., of 11, Queen Victoria-street, London, manufacturers of the "Root" water-tube steam boilers, has been formed into a private limited liability company, no shares being offered to the public. The business will be carried on at the same address, under the style of Conrad Knap and Co., as before, with the addition that Messrs. Penney and Co., Lincoln, will take an active interest in it, being represented on the directorate by Mr. Charles Cousins. Mr. Conrad Knap is the managing director of the new company.—Messrs. Alexander Mather and Son, engineers, millwrights and ironfounders, of Orwell Works, Dalry-road, Edinburgh, have now removed from Fountainbridge, where they have so long carried on business, to more commodious premises at Dalry-road. The new works are situated within five minutes' walk from Haymarket Station, North British Railway, off Dalry-road. The buildings have been specially designed and fitted to suit the requirements of the various branches of their manufactures, and a siding on the Caledonian Railway runs direct into the works. To facilitate the carrying out of all contracts entered into, considerable additions have been made to tools and machinery.—The business of the late Mr. Bradshaw Brown, recently carried on by him at Billiter-square-buildings, E.C., and Millwall, E., will in future be conducted by Mr. Harry Hooper, the late Mr. Bradshaw Brown's senior partner in the Millwall business, and Mr. Thomas W. Price, F.S.I.—for many years manager and confidential clerk to the late Mr. Bradshaw Brown—and the name of the firm will be Bradshaw Brown, Hooper, and Price.

HAULBOWLINE DOCKYARD.—In July last a committee was appointed by the Admiralty to inquire into and report upon the appliances of her Majesty's dockyard at Haulbowline, Queenstown, and to consider whether anything still required to be done to complete the fitness of the dock for carrying out the purposes for which it was constructed—namely, as an emergency dock in time of war, and to execute ordinary repairs to ships on the station in time of peace. The report of the committee has now been issued as a parliamentary paper. The subjects inquired into were embraced under the following heads:—Present appliances; *matériel*; dock; basin; towing power; offices, workshops, &c.; machines; general transport; lighting; water; cambers, bridges, &c.; and fire service. The committee strongly recommend the carrying out of various works, the approximate cost of which they estimate at £50,000, and they also think there should be a permanent staff of about 112 men organised, at a cost of about £8900 a year, though it is thought that the annual expenditure would probably be about £10,000. As regards superintendence, the committee said that the yard is somewhat peculiar in character, and in their opinion the work to be done is of such a character that it cannot be entrusted to the care of any officer of lower rank than a constructor. With him should be associated an inspector of shipwrights, and an officer of the rank of a second assistant engineer, or a foreman of fitters. It is, too, considered that the system of police should be assimilated with that of the other dockyards. The report adds:—"In conclusion, the committee wish to state that, although attention has been directed to other questions of an important character, the recommendations have been kept strictly within the terms of the reference, and the proposals contained herein—requiring an expenditure of only £50,000—are absolutely necessary, and have been arrived at after very careful consideration. By the expenditure of this moderate sum, the place, on which upwards of three-quarters of a million have been already expended, with no appreciable result, will be converted into a compact dockyard, from which a profitable return can be expected in time of peace, and capable of ready expansion in time of war, so as to be of considerable value to the nation. And, further, should it considered advisable to increase, at a future period, the scope of the work in this dockyard, that there is room available for the necessary extension, and that such an increase would result in still greater economy."

TORPEDOES IN FLIGHT





MODIFICATIONS IN THE DESIGN OF DESTROYERS.

THE great speed with which our flotilla of torpedo boat destroyers has been got together will account in some measure for the number of breakdowns which have taken place, and for the considerable modifications in design which are observable in the new vessels now being brought forward. Many of the difficulties which have been encountered are due, we cannot but think, to the stringency of the Admiralty conditions in regard to weight of propelling machinery and fixed displacement.

One of the most important and valuable modifications which have been effected is the abolition of bow torpedo tubes. The torpedo armament of these vessels is now confined to two torpedo guns of twin-tube character, which are worked from the deck. It was altogether a mistake giving the destroyers a bow tube. The effect of this singularly illogical contrivance, which we should be glad to see removed from our war vessels altogether, was to create in front of the earlier boats of the class under consideration, an enormous bow wave when the speed exceeded 22 or 23 knots, and, in a heavy sea with head wind, the violent blows which the bows received from the waves not unfrequently forced the door open, allowing water to enter and fill the fore peak. But there was another and more cogent reason for the abandonment of the bow tubes. It was feared that there was a chance of the torpedo being overrun during an action if the destroyer was steaming fast and discharged one of these missiles from her bow tube. In engaging an enemy the vessel would presumably be kept running at full speed, but as the extreme speed of an 18in. torpedo is only somewhat in excess of 28 knots, there would be every probability of its being overtaken by the boat, for the following reason. The torpedo does not start upon its run in a horizontal straight line, but in an undulating line, and the waves of this line gradually straighten out as the torpedo proceeds on its course. No matter how horizontally the torpedo is launched, it deflects at an angle when it touches the water, owing to its inclination to turn a summersault upon its head as the latter enters the denser medium. This sets up the wave action. The accompanying engravings, which are taken from two striking photographs published by Mr. West, of Southsea, show the movement very clearly. Though the torpedo has been launched almost horizontally, as seen in our first picture, the second shows it entering the water at an obtuse angle to its original course. In the engraving the vessel is seen to be at rest. But it is needless to say that the wave action would be greatly enhanced in the case of a torpedo leaving the bow tube of a vessel steaming at 27 or 28 knots. In such a case the tendency of the tail end of the torpedo to turn over, so soon as the head entered the water, or denser medium, would be so great that the undulations of the torpedo, at starting under water, would seriously affect its speed. The danger of over-riding would therefore be imminent. This is not a theoretic danger. Quite recently a large war vessel of high speed, after discharging a torpedo from her bow tube, overran it, struck it, and the air chamber exploded beneath it with great violence. The war vessel's skin was too stout to be affected by the explosion, but the incident sufficiently illustrates the importance of the argument. Had the torpedo been a charged one, the war vessel would have been sunk, and in the case of a "destroyer," the accident might possibly have been fatal, whether the torpedo was charged or not.

The "sitting down" of the earlier torpedo boat destroyers in the water, when running at high speed, has been modified to a great extent by hollowing out the run beneath the counter until it presents a completely flat surface to the water it is gliding over. This is a perfect remedy in a smooth sea, or even when it is blowing a little and the wind is on the beam. But when a severe head gale is encountered, and the little craft is pitching and scending, the greatest care has to be exercised in so heading the vessel as to prevent her counter flogging the sea when she comes down aft. There is, in fact, considerable danger of her frame being injured by the blows which she receives below her stern. This is a point only fully realised by naval officers who have had experience of these boats during a gale in a sea-way, and not one of which shipbuilders are likely to know much. But it is an important one, and its recognition is imperative.

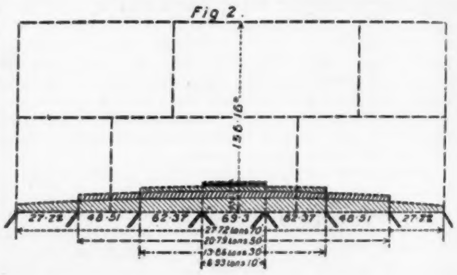
TIMBER BRIDGE CONSTRUCTION IN NEW SOUTH WALES.*

THE necessity for the economical designing of timber bridges in the Colony of New South Wales may be gauged from the fact, that in the last ten years some 680 timber structures have been erected at a cost of £634,000, so that any economy in a type design means a very large saving in the annual expenditure of the Colony. Formerly the wood lattice and vertical tie bars or suspenders was the type used for 65ft. to 100ft. spans. The defects in this design may be briefly summarised—weakness in suspension rods, no means of taking up slackness in braces, caused by shrinkage of timbers, and tendency of top chord to incline inwards owing to want of lateral stiffness. Although this type of truss has for many years carried the traffic without accident, yet in view of the increase in settlement and the greater risk of the structures being subjected to heavier loads, it was thought desirable in 1886 to adopt an improved design for 65ft., 75ft., and 90ft. spans.

These structures were designed for a distributed live load of 84 lb. per square foot of roadway and a traction engine weighing 16 tons, on a 10ft. 4in. wheel base, having 9½ tons on the leading wheels. The improvements in these trusses are the increased sectional area of suspension rods, the providing of means of taking up slackness in braces, increased lateral stiffness imparted to truss by splaying principals, the introduction of iron in lieu of timber side braces, the more general use of sawn timber free from heart, and the more effective splicing of chord.

In 1893, to replace the 1886 type of truss bridges, Mr. Hickson, M.I.C.E., Engineer-in-Chief for Public Works for New South Wales, approved of the author's designs for new standard type of truss bridges for 70ft. and 90ft. spans. The 90ft. span is designed for a traction engine of 16 tons and a distributed live load of 18·8 cwt. per foot run, or 7½ cwt. per lineal foot more than for the 90ft. truss bridge previously in use. The truss is divided into nine panels of 10ft., with a depth of 13ft. measured between centres of triangulations, and carries a 15ft. carriageway and two 5ft. footways. The timber generally employed is tallow wood for the planking and ironbark for the stringers, floor beams and trusses, the timber in trusses being cut free of heart; but in many districts the local timber, with a somewhat shorter life could be used for the planking and stringers.

Fig 2.



The flat decks in the old types of bridges resulted in water lying in pools on the surface of the planks, more especially in the centre of the roadway, where the wear is greatest; 3in. scupper pipes along kerb line, even if not choked up, are therefore of little service. To provide against this a camber of 1½in. in cross section of deck is provided in the new type of bridge, permitting of the quick escape of water through the large gratings at ends of spans. Unlike previous designs, 4in. transverse planking spiked to longitudinal stringers has been adopted, thus permitting of shorter lengths being obtained at a cheaper rate and of their being replaced with less trouble than diagonal planking. Longitudinal stringers varying from 10¾in. by 5in. to 9in. by 6in.—to give camber in deck—pitched 3ft. apart, are bolted to the floor beams, in lieu of the intermediate floor beams used in all previous designs, effecting a saving in cost, and permitting of the concentrating of the loads at the apices, thereby relieving the bottom chords of secondary stress.

In all the old types of trusses the suspension rods passed through the floor beams, and as the braces were also butted against the floor beams, the renewal of these timbers was rendered practically out of the question. In the latter design on another page, the floor beam, 15in. by 12in. spaced 10ft. apart, are placed between the suspension rods, admitting of easy renewal, and at the same time saving the expense of boring large holes through floor beams for the passage of suspension rods. With a view to renewals, the horizontal thrust from the braces is taken up by means of castings, having lugs 1½in. deep let into the chords, and, where two lugs are necessary, it will be noticed that the deeper lug is at the back of the casting, so as distribute the thrust over a larger area and reduce the risk of failure by shearing between the lugs.

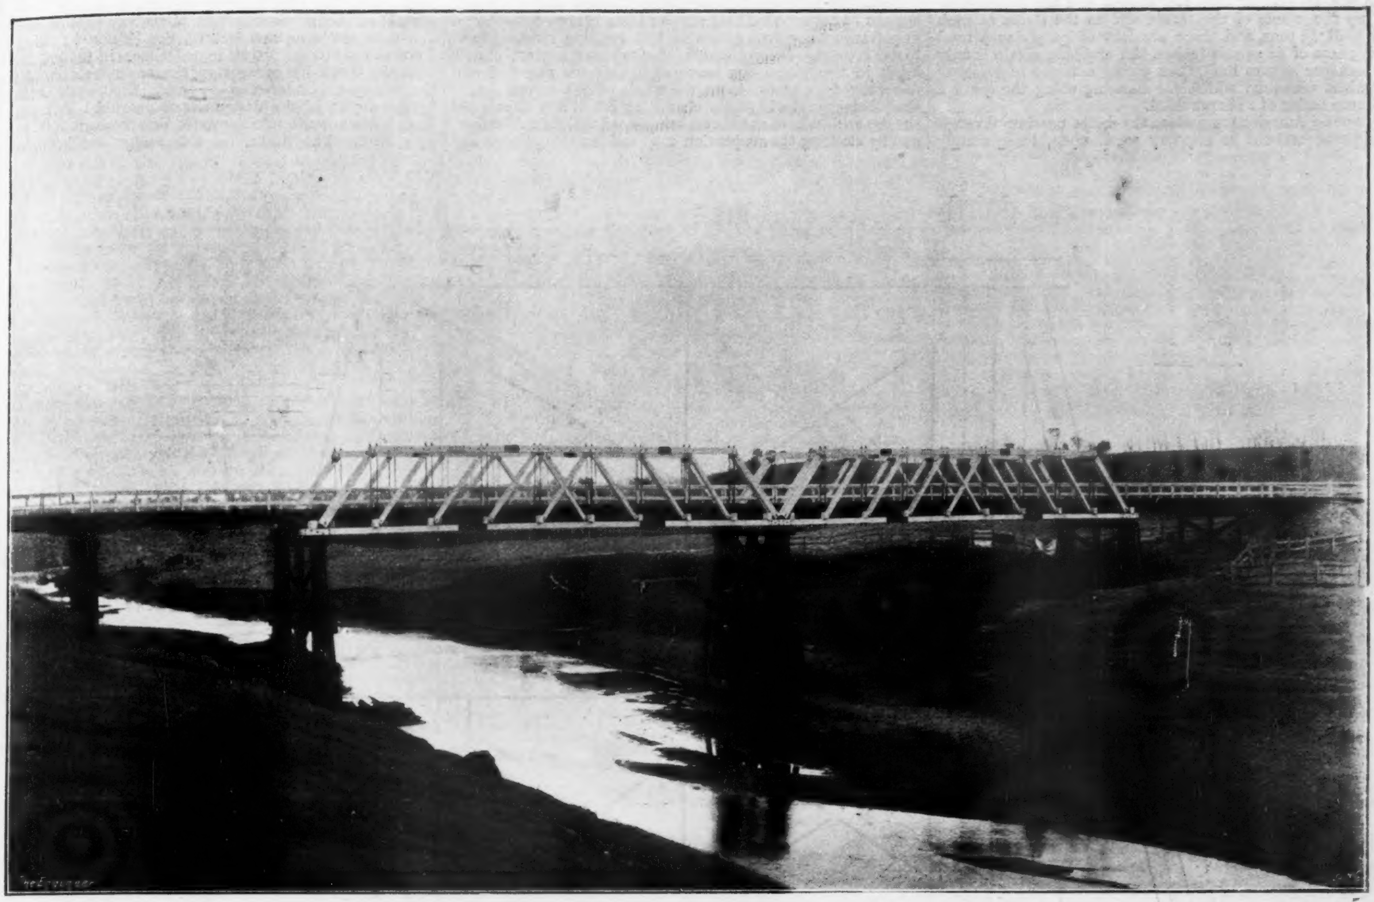
The advantage in using castings in lieu of a number of timbers bolted together to form butting blocks for the braces, is the doing away with to a great extent of one of the most troublesome questions in connection with timber bridge work, viz., the lodgment of water. No matter how carefully the timbers may be bolted together and painted, water will, after a short time, find its way between the surfaces

---

* Paper read before the Engineering Section of the Royal Society of New South Wales, September 18th, 1895, by Percy Allan, Assoc M. Inst. C.E.

TIMBER BRIDGE OVER GLENNIES CREEK, NEW SOUTH WALES

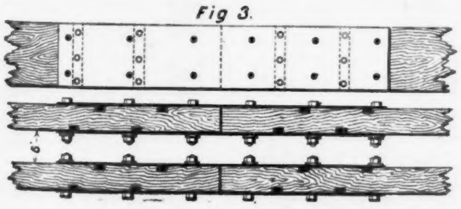
MR. P. ALLEN, ASSOC. M. INST. C.E., ENGINEER



with its accompanying ill effects; again, in the endeavour to get a close joint along the exposed surface, the butting surfaces will oftentimes be made slightly concave; in such cases when the water does penetrate—there being no escape—the evil will be intensified. The batter braces, which consist of two 14in. by 6½in. timbers bowed and stiffened with hardwood distance pieces, have been substituted for principals; thus reducing the horizontal thrust to such an extent as to permit of the introduction of castings in lieu of the large timber butting blocks, with the heavy bolts, previously necessary.

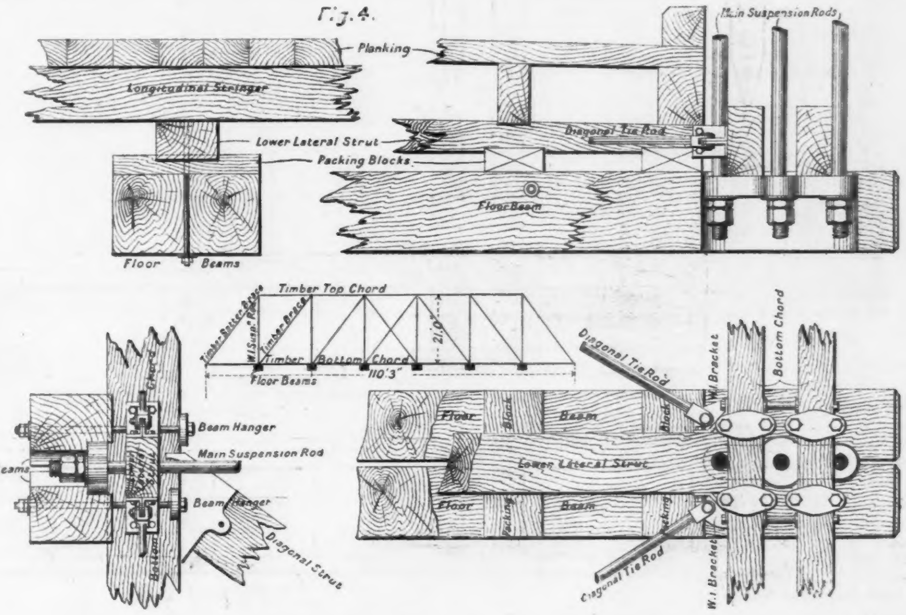
In most of the American Howe trusses counterbraces are introduced, with a view of stiffening laterally the main braces, however the braces in the truss under consideration are comparatively short, and as columns require no lateral stiffening, counters in the end bays are therefore not provided. As all the braces in the truss are at the same angle, any shrinkage in the timbers can be taken up by means of the suspension rods; the iron wedges in the 1886 design are, therefore, not arranged for in this later type of truss. The main braces are formed each of two timbers 8in. by 4½in., bowed to prevent warping and twisting, and connected together with bolts and hardwood distance pieces, all the timbers being connected to the cast iron shoes at the top and bottom with ⅞in. bolts. Formerly it was the practice to have the top chord in one piece 16in. by 14in. by 42ft. long, which, having to be bored for the suspension rods, rendered renewal very costly, if not impracticable. As one of the objects in designing a new type of truss was to permit of renewals, a chord, consisting of two timbers 14in. by 6½in. bowed and stiffened with hardwood distance pieces, was adopted, thus securing better timber and giving greater stiffness as a column. The side braces adopted in previous trusses being a source of inconvenience when footways had to be provided, the author decided to design this chord as a column with a varying load, unsupported in a lateral direction; none of the text books, however, consulted by the author treated of such a case. The stress in the top chord of a 90ft. span ranges from 69·3 tons in the centre to 27·72 tons in the end bay.

Fig 3.



As the maximum stress extends only over a length of 10ft. of the chord, it would be obviously incorrect to take this stress on a column the total length of top chord, nor could it be assumed that this maximum stress was acting only on a column 10ft. long. The author, therefore, has dealt with the case in what he submits is a practical way of looking at the question. Starting with the end bay there is a stress of 27·72 tons, which extends for the whole length of the chord—70ft. Taking the least diameter, the ratio of length to least diameter is 48 to 1, and the ultimate buckling strength of a timber column of this proportion being 2·36 tons per square inch, the area required on the point of buckling would be 11·74in., whilst at the ends of the column the area required, when at the point of failure by direct crushing, would be 5·87in. Setting up these ordinates and plotting in as a parabola, the area shown on diagram—Fig. 2, page 524—is obtained. In the second bay the stress is 48·51 tons, extending for a length of 50ft., but as part of this stress, 27·72 tons, has already been provided for, it leaves only 20·79 tons to be dealt with. Taking the ratio of length to diameter, this gives a column of the proportion of 36 to 1, requiring an area of 6·77 square inches when the column is on the point of buckling at the centre, and an area of 4·4 square inches when on the point of failing by direct crushing at the ends, the required additional area being shown on the diagram, page 524, Fig. 2. In the third bay there is a stress of 62·37 tons extending over a distance of 30ft.; 48·51 tons of this stress has already been dealt with, leaving only 13·86 tons to be provided for. Proceeding as before, the area shown in centre is arrived at; in the middle bay the stress is 69·3 tons extending over 10ft., of which 62·37 tons has been provided for, leaving 6·93 tons to be arranged for.

Fig. 4.



The whole of the varying stresses having now been dealt with, the outer dotted black line represents the total area required when the column would be on the point of failing. The actual net area of timber provided is 156·16 square inches, Fig. 2, page 524, and as the maximum area required at the centre is only 23·65 square inches, the column has a factor of safety of 6·6 against buckling, irrespective of the stiffness imparted by the splaying of the feet of braces. The bottom chords of the 1886 type of trusses for 90ft. spans 14in. by 18in. were built up of four 14in. by 4½in. flitches, planed on all surfaces to ensure good butting, the whole being drawn up with ⅞in. bolts. This is a costly and undesirable design of chord, offering as it does, after a few years, an entrance for water between the flitches, causing decay, which is especially serious on account of the design of truss being such that the bottom chord cannot be renewed, thus necessitating in some cases the replacing of the whole structure, which under other circumstances, with a few new flitches, might have lasted for several years longer. Again, some of the flitches are 53ft. 6in. long, and having to be free of heart and sapwood, are difficult to obtain, and this oftentimes occasioned delay in the erection of the structures, the simple-minded sawmill proprietor supplying all the short and profitable sizes in the bridge, and then pleading inability to supply the more costly flitches.

The bending stress in the bottom chord of the new truss having been eliminated by the omission of intermediate floor beams, only a direct stress has to be provided for, resulting in a considerable reduction in the sectional area of the bottom chord, which consists only of two flitches, 12in. by 5in., placed 6in. apart, thus being always accessible to the brush, and permitting of the renewal of these important members; again, the longest flitch is only 36ft., a length easily procurable. Perhaps the most important connection in a timber truss is the bottom chord joint. Fig. 3 shows the cover adopted for the new type of truss. As the two flitches in the bottom chord are independent of one another, the whole stress in each flitch has to be taken by the two 12in. by $\frac{7}{16}$in. wrought iron plates placed on either side of the beam; on each of these plates four wrought iron strips 12in. deep by 1¾in. wide by 1in. deep are rivetted; these strips are let tightly into the timber, and are designed to take up the whole of the stress, and as the stress in each flitch is 31·18 tons, and there are four strips giving a total bearing area of 48 square inches, the crushing strain is only ·65 tons per square inch, thus giving a factor of safety of 7½ against crushing, whilst for shearing along the grain a minimum factor of 15 is provided.

Following American practice, the bolts passing through cover plates are not in any way relied upon, being simply provided to keep the plates up to their work; however, as the bolts had to be provided, the author determined to obtain the benefit of them, and arranged for the bolts to be turned and passed through drilled holes in the plates. The above joint has also met with the approval of the engineer-in-chief for railways, and has been adopted for some of the proposed bridges on the Narrabri-Moree line, whilst in some of the later American railway bridges it has proved successful, despite the fact of it being necessary in some of these pine bridges to arrange for fitting in eight strips in each plate, instead of four, as shown in Fig. 3. With this joint, requiring as it does only a straight cut, no difficulty is found in obtaining an almost perfect bearing with ironbark timber, and so far in the 146 joints in the bridges already erected in this Colony, no trouble has been found in effectively making this connection. The suspension rods, which in the author's design of truss have a minimum diameter of 2in. and 1¼in. respectively, are placed on either side of floor beams, and pass through the space between the chords, thus saving the boring of holes through chords and floor beams, and permitting of easy removal in connection with the system to be adopted in renewing chords.

One of the features of the new type of truss is that any member can be renewed without staging from below—a matter of importance when deep gorges or fast running streams have to be crossed. Briefly stated, the top and bottom chords being in two pieces, the suspension rods are removed and re-arranged so as to throw the whole weight on one flitch; there being no strain on the remaining flitch, any member of the top and bottom chord can be replaced with sound timber; and by slacking the suspension rods and inserting temporary struts, any of the braces can be renewed, whilst the renewal of the cross girders is obviously a simple matter. In the superstructure of one of the new 90ft. spans carrying a 15ft. deck, there is 500 cubic feet less timber than in the 1886 type of truss, which, in conjunction with the greater ease in framing together—notably in the bottom chord, where no fitting is required—the fewer bolt holes to be bored and the short lengths of timber employed, effect a saving of over £100 in each 90ft. span. The economy is more marked when it is considered that the old trusses were designed to carry a 15ft. carriageway, whereas the new trusses are designed to carry two 5ft. footways in addition to a 15ft. carriageway. Thus it will be seen that the later design of truss bridge offers greater facilities for traffic at a much reduced cost.

The piers carrying truss bridges vary in accord with local circumstances; one of the heavy type is that shown in Fig. 6, consisting of nine vertical piles 12in. by 12in., arranged in groups of four under heels of trusses, also one short vertical pile upstream and two short vertical piles downstream, carrying up and downstream struts. The pier is stayed with wales and braces 12in. by 6in., and internal compression struts 12in. by 12in., seated on hardwood chocks secured to piles with bolts, the chocks being set end on to do away with shrinkage, the previous system of seating butting blocks on the wales not being satisfactory, the blocks shrinking away from the struts, resulting in a slackness in the bracing. At Glennies Creek, near Singleton, the superstructure of one of the 90ft. spans cost, erected in position, £450, while in the same bridge a pier of the design above described 28ft. 4in. high from bottom waling to capwales, driven about 16ft. to rock, cost £200. The timber for this bridge was brought from Cape Hawke to Newcastle by sea 61 miles, thence forward by train to Singleton 49 miles, thence by road 9 miles, or a total carriage of 119 miles.

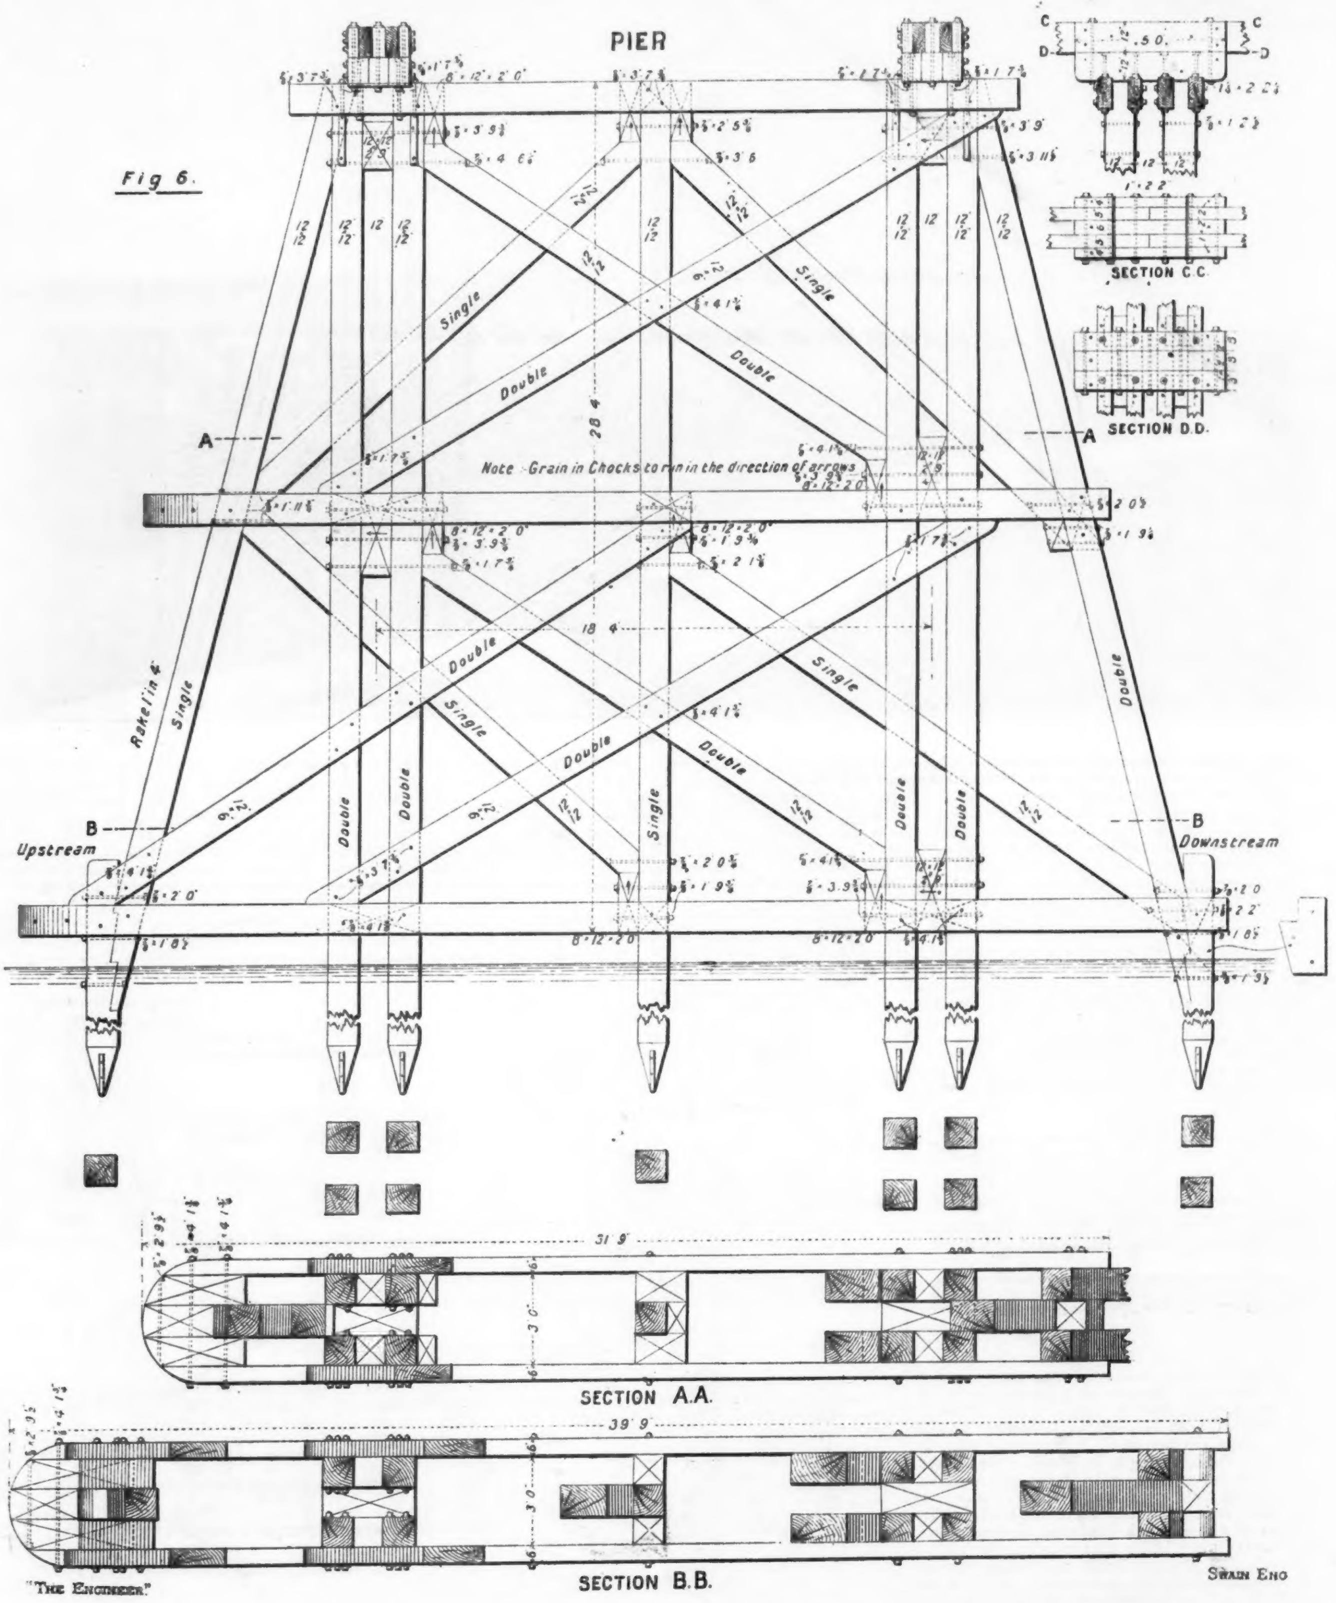


Fig 6.

Late in the year 1892 it was decided to erect a new bridge over the Murrumbidgee River at Wagga Wagga. Design were submitted for a light iron lattice girder bridge, carryin a timber deck resting on iron cross girders, but the amount available being insufficient, the author's design for a timber truss bridge was decided upon, and a contract for construction let to Mr. S. Stokes on October 4th, 1893, at schedule rates, totalling £12,604. As this bridge is now nearing completion, and, reckoned by the floor space per span—3165 square feet—is by far the largest timber structure yet attempted in the Colony, a short description may be of interest:—The bridge consists of six timber trusses, resting on iron cylinder piers and concrete abutments, forming three spans each of 110ft. 3in. centres, also nine approach spans each of 35ft. The trusses stand 27ft. 1in. apart, centre to centre, and are connected by a top and bottom system of lateral bracing, angle and portal brackets being introduced in the top system. Each truss contains seven panels of 15ft. 9in., and, being 21ft. deep between centres of triangulations, enables full provision to be made for a loaded wool wagon, which requires 17ft. 6in. head room. The truss spans are designed to carry a distributed live load of 1·2 tons per foot run, or a concentrated load of 16 tons. The carriageway is 24ft. 4in., whilst one 4ft. 6in. footway is arranged for, so that the requirements of the wool traffic will be fully met, a wool wagon measuring 11ft. 6in. when loaded and 6ft. 6in. when empty. The wind pressure allowed for is 56 lb. per square foot, on the exposed surfaces of kerbs, stringers, and ends of planking, and on twice the area of the handrails, ends of girders, top and bottom chords, braces, and verticals, the whole being taken as an uniform moving load.

Whilst the author is aware that on the occasion of the Dandenong gale, September, 1876, the wind is recorded at the Sydney Observatory to have attained a velocity of 153 miles per hour, equal to a pressure of 115 lb. per square foot, yet the author considers there would be no justification for assuming that such a phenomenal pressure would extend over such a large area as that occupied by such a bridge as that under consideration, and in support of this opinion, points to the existing structures throughout the Colony, few if any of which would be now standing if ever subjected to anything approaching even the pressure allowed for in the Wagga Wagga bridge.

The minimum factor of safety adopted for timber in the trusses is 7 for the stresses due to combined dead and live loads. Although this factor may appear to be somewhat liberal, yet it must be borne in mind that the ultimate strength of ironbark has been taken from tests made on small specimens of picked timber, and that a reduction in strength is only to be anticipated in large scantlings. Again, the flitches being sawn, the grain will run more or less across the line of the sticks, and as defects in timber are so liable to escape even the most severe inspection, it is necessary, in the opinion of the author, to make a liberal allowance to cover such contingencies.

The floor system adopted in this bridge presents some novel features, which, so far as the author is aware, have not previously been adopted in any structure in any part of the world —Fig. 4. The main points kept in view were:—(1) The necessity of having a camber in deck to permit of the quick escape of water. (2) The desirability of having a low lateral system of wind bracing, so arranged that the triangulation lines of the wind bracing and the triangulation lines of the truss members would intersect at a common point in the bottom chord. (3) The distribution of the load, so as to get each pair of the floor beams to act as one. (4) The necessity of concentrating the loads at the apices, as, with the section employed, two 14in. by 7in. timbers, no additional stress was permissible in the bottom chords.

The deck consists of 4in. transverse planking spiked to 12in. by 6in. longitudinal stringers, seated on the lower lateral struts. The lower lateral strut is 12in. wide by 8in. deep at centre, adzed down on top surface to 6in. at ends—to give camber in deck—the centre line of strut being placed in the same plane as the centre line of the bottom chord. The ends of the lateral strut are secured to bottom chords by wrought iron brackets, and to these brackets are attached the diagonal tie rods, the centre lines of which, if produced, would intersect at the centre of bottom chord; the triangulation lines of the wind-bracing and truss members thus intersecting at a common point and avoiding all bending stress. The lateral struts are tightly lapped one inch over nine 12in. by 4in. sawn packing blocks 2ft. 5in. long, resting on the floor beams. These blocks not only pack the lateral struts up to the same plane as the centre line of chord, but what is of just as much importance, equally distribute the whole load over the pair of floor beams. With a panel length of 15ft. 9in., and a span of 27ft., the resulting load is so great as to necessitate the use of two floor beams, each 14in. wide by 16in. deep, spaced 1in. apart—to permit of a current of air and avoid boring for stringer bolts, and connected together with eleven ⅞in. bolts passing through 1in. cast iron distance washers.

As the overall width of these two floor beams is 2ft. 5in., it was impracticable, without fouling the braces and suspension rods, to rest them on the upper edge of the chord. They are therefore suspended from the chords by sixteen beam hangers 1⅛in. diameter passing on either side of the flitches of chords. The author is of opinion that for timber railway bridges of large span, the floor [system above described offers some advantages, inasmuch as shock from trains would be reduced by the lateral strut and distributing blocks acting as a cushion; whilst the beam hangers being so short, a large allowance could economically be made for dynamic action, which action would be materially lessened by the time the main suspension rods were reached. In connection with the construction of timber bridges, the financial aspect of the question is of the utmost importance. Like all engineers, the author would prefer—if economy had not to be considered —to construct metal bridges, but in a new Colony where the trend of the traffic is likely to be diverted by many circumstances, difficult, if not impossible, to anticipate, it would seem preferable in such localities to construct timber structures with a small capital outlay, rather than spend large sums on works of a more permanent character.

For many years there has been a disinclination in this Colony to build other than permanent traffic bridges out of loan funds, yet as harbour works and railway works, in which timber structures, sleepers, fencing, &c., represent no inconsiderable portion, are built out of loan funds, the author submits there is no reason why traffic bridges should not also be constructed out of borrowed capital, provided it can be shown, first, that they are more economical not only in prime cost but in annual charge, and secondly, that provision be made for their renewal or repayment out of revenue. It may be urged, in these days of cheap steel, that it is against the practice of other parts of the world to construct timber bridges, but in what other country could be found timber with a tensile strength of eight tons per square inch, a crushing strength of 4¾ tons per square inch, and a shearing strength along the grain of one ton per square inch; or bridges totally unprotected from the weather with a life approaching anything like, amongst others, the following:—Bridge over Cox's River, at Glenroy, 28 years old; bridge over Bell River, 32 years old; bridge over Macquarie River, at Dubbo, 32 years old; bridge over Murrumbidgee River, at Wagga, 33 years old; bridge over Duck River at Paramatta, 34 years old; bridge over Cudgegong River, at Rylstone, 34 years old; bridge at Berrima, 35 years old; bridge over Murray River, at Albury, 36 years old.

The first metal bridge in the world is said to have been erected over the Severn at Colebrook Dale in 1779. This bridge consists of a cast iron arch of 100ft. span, the structure being thus 116 years old. Wrought iron and steel bridges are, however, of a much later date, and the fixing of the life of such structures is to a great extent only a matter of conjecture. In connection with this matter Waddell says: "There is no reason why a well-designed iron highway bridge—when properly cared for—should not last for ever. Under loads which are light and slowly moving compared with those of railway bridges, the iron cannot possibly wear out, and when properly protected from the weather cannot rust." The author, therefore, to make everything favourable to the metal bridge, in a comparison of its cost with that of a timber bridge, has assumed the life of the former as infinity, whilst the timber bridge has been taken at only twenty-five years—a life, it is only reasonable to expect, will be much exceeded with the better type of structure, the more careful inspection of timber, and the greater care in erection that now obtains.

The whole of the timber for the Wagga Wagga bridge was brought from the Northern Rivers to Darling Harbour, about 150 miles by sea, thence by railway to Wagga Wagga—310 miles—or a total carriage of 460 miles. The contract cost for one timber truss span at Wagga Wagga is £1300, and the estimated cost of one span of the iron lattice girder design, complete on bearings, was £2800—Colonial manufacture. Now, to compare the relative cost of these two bridges on the basis that the planking in each bridge will require renewal every 12½ years, the remaining timber work every twenty-five years, and that the ironwork is everlasting, it is necessary to ascertain how much per annum it will take to keep these bridges "trafficable" for ever; in other words, to ascertain how much per annum it will cost in each case for interest on the prime cost—tarring, painting, removal of old material, and renewing of each portion as it wears out.

Having obtained the annual charge for each bridge, the difference represents the saving effected. The comparison is as follows:—

Annual Charge for Iron Design.

Item.	Prime cost.	Interest.		Renewals.	Sinking fund to provide for removal and renewal of timber.		Maintenance.	Total.
		Rate.	Amount		Life.	Amount		
	£		£ s. d.	£		£ s. d.	£ s. d.	£ s. d.
Planking ..	180	4 p.c.	7 4 0	220	12½ yrs.	13 18 2	—	21 2 2
Stringers ..	130	4 p.c.	5 4 0	170	25 "	4 1 8	—	9 5 8
Ironwork ..	2490	4 p.c.	99 12 0	Nil	Infinity	Nil	—	99 12 0
Painting ..	—	—	—	—	—	—	60 0 2	60 0 2
£	2800				Total annual charge	..		£190 0 0

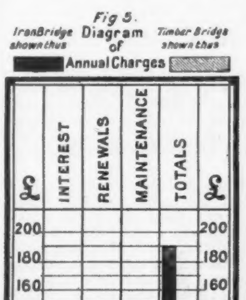
Annual Charge for Timber Design.

Item.	Prime cost.	Interest.		Renewals.	Sinking fund to provide for removal and renewal of timber.		Maintenance.	Total.
		Rate.	Amount		Life.	Amount		
	£		£ s. d.	£		£ s. d.	£ s. d.	£ s. d.
Planking ..	180	4 p.c.	7 4 0	220	12½ yrs.	13 18 2	—	21 2 2
Stringers, trusses, floor-beams and remainder of timber in superstructure	630	4 p.c.	25 4 0	950	25 "	22 16 8	—	48 0 3
Ironwork ..	490	4 p.c.	19 12 0	Nil	Infinity	Nil	—	19 12 0
Painting ..	—	—	—	—	—	—	51 5 7	51 5 7
£	1300				Total annual charge	..		£140 0 0

Thus it will be seen that there is a saving of £50 per annum in favour of the timber bridge, which has, at 4 per cent. interest, a capital value of £1250. See Fig. 5.

The author has also designed timber trusses for spans of 130ft. and 153ft. The latter truss altogether differs from the Wagga Wagga bridge, four flitches instead of two being placed in the top and bottom chords, and as for purposes of renewal a larger sectional area is provided than is actually required for direct tension, the floor beams can in this case be seated directly on the upper edge of the bottom chord. The flitches of chords being spaced only 3in. apart, whilst allowing of a free current of air and room for painting, permits of the adoption of channel iron gib-plates for suspension rods in lieu of the heavy forgings used at Wagga Wagga, whilst the castings are, from the same cause, much lightened. Again, in the lower lateral system diagonal timbers and transverse tie-rods have been arranged for, which is somewhat more economical than the diagonal tie-rods used at Wagga Wagga. In conclusion, the author desires to record his acknowledgments to Mr. Hickson, M.I.C.E., for his courtesy in lending models, plans, and photographs to illustrate the several works mentioned in the foregoing paper.

Fig 5.



The Colony of New South Wales is fortunate in possessing an almost unlimited supply of hardwood of exceptional durability and strength, the most favoured for engineering purposes being "ironbark," which in bridges totally unprotected from the weather has a life in many structures exceeding twenty-five years, whilst the average of a number of tests gives its tensile and crushing strength as 8 tons and 4½ tons respectively. Full advantage has been taken of this valuable natural product, no less a sum than £634,000 having been expended in the Colony of New South Wales during the last ten years in the construction of 680 timber bridges. The Glennies Creek, New South Wales, designed by Mr. Percy Allan, Assoc. M. Inst. C.E., acting under Mr. Hickson, M.I.C.E., Engineer-in-Chief for Public Works, has been adopted as a standard type throughout the Colony for spans of 70ft. and 90ft. Sixteen bridges have been erected of a total length of 4300ft. 1in., containing twenty-six truss spans of this type, which have proved both economical and suitable to the requirements of the traffic. The loads allowed for are a traction engine of 16 tons on a 10ft. wheel base, with 9½ tons on the leading wheel and a distributed live load of 84 lb. per square foot, equal to 18·8 cwt. per foot run of bridge. The timber in the trusses is cut free of heart, and is so placed as to be always accessible to the brush, whilst at the same time permitting of any member being replaced without staging from below.

LETTERS TO THE EDITOR.

(*Continued from page* 518.)

THE JENNY LIND: A LINK IN LOCOMOTIVE HISTORY.

SIR,—In THE ENGINEER for January 10th in the present year you published an engraving of the Jenny Lind of the Midland Railway, and an account of how the Jenny Lind type came into existence. The special feature of it is that the driving wheels have only inside bearings, and the leading and trailing wheels outside bearings. It has been considered by some persons that I have advanced claims in regard to the design of this type which are not in accordance with the facts. Will you favour me with space to deal with these charges, and to add a link, not without interest, to the history of the locomotive engine?

I would gladly have kept out of a discussion if it had been possible, as any part I may have to take in it must be personal, and may appear to be egotistical; but my readers will excuse me, if I am forced into this, as it will be necessary in the nature of the evidence I must give to meet the objections which have been raised, and therefore cannot be helped. Again, as a reason for the delay, which has been unavoidable, I have been so busy with practical work as not to have had the time at my disposal necessary to treat the question with the attention due to the importance it has assumed as a question of locomotive history, involving on my part the hunting up of old records, drawings, tracings, &c., as well as other collateral matter to prove my position, as I shall not bring into the case any haphazard accounts or remarks, but only such records as I have notes or drawings to prove.

First, I think I should say an explanatory word about an article which appeared in THE ENGINEER of the 10th of January, 1896, from which all this correspondence has arisen. Asked by you, Sir, for anything I could tell about the Jenny Lind, to save myself trouble, without much thought I offered you my diaries. These diaries were, of course, originally written without the idea of any one seeing them, and were records kept only for my own information. No wonder then that in selecting information from my journal, my name should have come out prominently—this had not struck me at the time, as it was the engine I was thinking of rather than myself in connection with it.

Next I will answer the question often asked, why I have not spoken earlier. When the Jenny Lind came out, it was the custom that the heads of a works or manufactory had the credit of all that was done there. This was perhaps a necessary result of the circumstances, and it is so more or less still in every walk of life—the expert who perhaps really does the work not coming to the front at all—and I, of course, never for a moment thought of interfering with usual custom. As an instance of this custom, the link motion has always and is still called and quoted for as "Stevenson's link gear." Meanwhile everyone knows who invented it. In this sense then, as Mr. Tomlinson puts it in his address, Mr. Wilson and Mr. Fenton "produced" the Jenny Lind.

Then it is asked why I did not come forward when Mr. Tomlinson gave his presidential address, which he used to speak of as his "recollections." This address—contrary to my usual custom—I had not seen. I heard it before the meeting of members, and then I still accepted the ruling of the old custom, that the heads got the credit, for, to say the least, it would have been very bad taste to burst out then. But, further, I did not care to claim the honour from an old and very much respected and esteemed master and friend, such as Mr. Fenton had always been to me, and perhaps to more young engineers coming forward than any other man in the profession, and I am glad here to bear this testimony. Besides, I felt that from that gathering of brother engineers I had already received such unstinted goodwill, credit, and kindness for advances in engineering science and practice distinctly my own, that I should have felt it a graceless thing to seem to snatch at the laurels worn by another, that I was well content to let the matter rest as it was; and it has been the hue and cry raised by only partially informed correspondents that has now forced me into the matter.

Before going into facts, and as clearing away, as I think I can, all the objections, I may be perhaps allowed to say a word or two on the many letters which have appeared on the subject, and I think by answering the objections raised in one or two I can cover the whole of what requires notice, and by massing the rest without specially naming any, I shall get at the most simple treatment of a subject which has become pretty well confused.

The bulk of the ordinary letters in all the papers appear to be written by those who have only a very partial and often after knowledge of the matter, and in most cases only hearsay, so some of the intended facts are mixed up in amusing confusion. Many speak of the "Jenny" as originally built for the Midland Railway in 1848. This was not so. The first order was given by the Brighton Company, and the engine was designed for that company, and the first went there. Then others speak of 1848 as the date of the type. The design of the first 800ft. surface engine was made in 1846, and the first engine was finished in May, 1847.

Referring to the correspondence, the main question has been treated by one correspondent thus: having first admitted—as he has done—that he had had "to rely on books and statements, and the report of others;" on such very unreliable evidence he thinks fit to lay down the law for your readers and to say positively, "Mr. Joy did not design the Jenny Lind." This statement may stand for what it is worth, after the admission of the source from which its authority comes, but it must bear the test of the facts; and as to designing—what is designing? Call it what you will; I will give a simple statement of the events which is not founded on the report of others, but all from personal knowledge, such as in every point and date can be proved by my diaries, drawings, and tracings. I can then well afford to leave the decision with your unbiassed readers as to my share in the matter; but for those who are determined only to believe what they wish, let them do so if it pleases them, but no amount of this sort of assertion will make it true, or will destroy the facts or alter history, but will only give more prominence to the facts.

Another correspondent quotes what he calls a "very full statement" professing to be a very clear account of the origin of the Jenny Lind—this has also been copied into other papers. He says of it, that it formed part of the address of Mr. Tomlinson to the Institution of Mechanical Engineers, May, 1890. As a member of that Institution I have examined my own authorised copy of these "minutes," which I have, further, the secretary's sanction for saying contains everything that was included in that address. Yet there is not a syllable of this "full statement" in it. Mr. Tomlinson is also further made responsible for a very strange remark, "that the Jenny Lind was the result of an accident." Not a word of this either appears in the address or in the few remarks, not amounting to a discussion, which followed. Wishing to trace the authority of the publisher of this "very full statement," I sought for his name in the list of the members of the Institution, without finding it. I was present at the reading of the presidential address. I heard nothing of all this, and there is nothing of it in the "minutes," the only official, and so reliable authority on the subject. So it seems to me that your readers must conclude with me that the "statement" and the "accident" dissolve together into only an ingenious invention. No doubt such an accident has happened at some time, and forms the basis of this tale, but not to a Railway Foundry engine of that date, and not with the result ascribed.

And it is utterly useless to make any fresh or explanatory statements to build up this theory, as neither the "full statement," so much relied on, nor the accident theory, appears in the authorised copy of Mr. Tomlinson's address, or in any copy; so there's an end to it. This can be proved by any one by reference to the minutes, at the rooms of the Institution, 19, Victoria-street, Westminster. I will now turn to the facts, and go on to relate what did transpire at Railway Foundry during that eventful year of 1846, and so prove how this apparently plausible "statement" could not have happened; that the accident described could not have occurred, and so that the "Jenny" could not have been the result of an accident. Then I will show by the continued narrative of the circumstances, how the Jenny Lind did come to be what she was.

"In 1846 E. B. Wilson and Co., of Leeds," *certainly did not build* "a number of standard engines with single driving wheels, 6ft. diameter, and double frames." I say this of my own personal knowledge, as I was there to see. First, because they had no such standard engines at that time or at all; and, secondly, because during the years of 1845 and 1846 the works were fully occupied in building other engines to order, all of the long boiler type, which was then the favourite engine. Nor were any such engines with double frames to drivers built at Railway Foundry in Mr. Wilson's time at all, since January, 1845, when he took the works, nor before that, in Sheppherd and Todd's time, back as far as June, 1843. Through all this time I was there, first as pupil, then as chief of the drawing-office, and everything had to pass through my hands, and if these engines had been built during the time assigned to them I should have had to make the drawings for them, or to superintend them, and this certainly was not the case; so I can say positively they were not built, nor were there drawings of this class of engine in the drawers before that time, or we pupils were certain to have found them. Again, if the accident had happened, as a mechanical question, the details would have been brought to the drawing-office to be reported there, as the proper place where all such matters were recorded. I have not the smallest recollection of this at the time, nor afterwards, when classifying the records for use; and an event so important, even controlling the design of an engine, could not so have sunk into oblivion.

When Mr. Wilson came to the foundry in 1845, the productive power could not at most have been over ten or twelve engines per annum, but he found no work of moment going on. This, however, he soon remedied. To begin with, he took an order early in the year for six engines for the Manchester, Bury, and Rossendale Railway Company, Mr. Cawley being engineer. These were long boilers. By August he took another order for six engines for the York, Newcastle, and Berwick Railway, Mr. Thos. Cabry. These also were long boilers. Thus the productive power of the place was already considerably over-crowded for the year, and proving that I have not over-stated this, the first engine of the first order was not finished till March 1st, 1846, so that 1846 began very full of work, and another little order dropped in in spring for a contractor's engine. Then by summer Mr. Wilson was bringing in more orders, this time it was six passenger engines and six goods for the Leeds, Dewsbury, and Manchester Railway, the line on which Mr. Fenton had been engineer. These engines had some of the features of the long boilers, and the outside cylinders combined—see Fig. 1—but the whole of these engines for 1845 and 1846 had inside bearings only; indeed they were the ordinary style most in favour there, but among all there was not one outside bearing to twist off, and to give the possibility of "the accident." Thus the Railway Foundry was kept full of work, and no room, and no time left for building the "standard engines," on which so much has been made to rest; indeed, if the Railway Foundry had a standard then, it was for long boilers and inside frames only. I have typical tracings of all the above engines, but not a vestige of the so-called "standard."

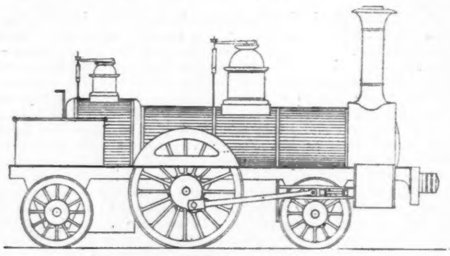


Fig. 1—L. D. M. RAILWAY, 1845

So having now proved, on the one hand, that the "Jenny" could not have been the result of an accident, I will next show some of the causes which brought her about, and made her what she was. To do this I must proceed with my narrative, and so next come to the Brighton Company's order towards the end of autumn, 1846. This was for ten passenger engines, to be built to the drawings of their superintendent, Mr. Gray; ten others had already been ordered from Messrs. Hackworth and Co.; these engines were all to be fitted with the Gray expansion gear, and throughout in accordance with Mr. Gray's really advanced ideas. From my position as chief in the drawing-office, I was sent for, and received my instructions from Mr. Wilson to go at once to Brighton, to take drawings and all particulars from Mr. Gray.

Mr. Gray being very much engaged during the day, sent me out with an engine pass, to see what I could on the line, working all the evenings when he could be present to see that his instructions were recorded. Another draughtsman was there also for Messrs. Stothert and Slaughter. With such freedom on the line, there was hardly a class of engine I did not have a run on. One of the Gray's engines—Fig. 2—had come from Hackworth's, and I did not fail to make a very intimate acquaintance with her. She was, though a heavy and lumbering engine to look at, a fine engine to pull, and she could run, and was very steady and very easy.

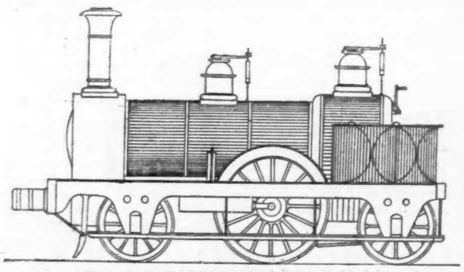

Fig. 2—L. B. AND S. C. RAILWAY, 1846

I spent three weeks taking particulars of these engines, but on my return to Leeds at the end of October, I had hardly got to work on the drawings when orders came to stop the engines, and to furnish a design of our own. This work, of course, naturally fell to my lot. And Mr. Wilson and Mr. Fenton, who was now general manager, met in my office over the drawing-board, and it was decided to go to work, naturally, on an engine of the class we were then building, and so to work out some combination of the long boiler and outside-cylinder type. The last of these we had under construction were the six passenger engines for the Leeds and Dewsbury Railway. These were outside-cylinder engines, 6ft. single drivers, with inside bearings only, and inside frames running the whole length of the engine, crowding up the fire-box so that little more than 60ft. of surface could be got in. I worked on these lines for about a week at the office, twisting the design into every possible form, and had made about ten general designs, when on Saturday about noon Mr. Fenton came into the drawing-office, and said we would try an inside-cylinder, 15in. by 20in., with 6ft. single driver, and as much heating surface as I could get in. These were all the directions I received. I was pretty sick by this of scheming engines to no good, and, as everyone else had gone, I left, too, for was it not Saturday afternoon, and a holiday? And from that hour till nine o'clock on Monday morning I saw no more of the Railway Foundry or anyone connected with it.

But on arriving at home, where I always had a sheet of drawing paper stretched ready for anything that might turn up, I took the fancy to try what I could make of the engine with such a "free hand" to work with, and the bias of my old Sheppherd and Todd training, including my familiarity with the engines Ariel and Orion, as well as my recent very satisfactory experience of the new engine at Brighton. Without throwing aside the type of the engine I had so recently been working at—the long boiler—I naturally associated the older predilections revived by the newer engine at Brighton, and the shortened inside frame allowing the wider fire-box, by which 80ft. of surface was easily got in, carrying on this frame the inside bearings only for the driving wheels, and adding an outside frame for the leading and trailing wheels to give ample ground surface to get steadiness. Then getting the boiler as low as possible—the "fad" then believed in to get steadiness—a very neat-looking engine came out without any great changes, and no invention, but really the result of the survival, or rather the selection, of the fittest elements of the various types of engines worked at from the first, the best points of each combining to form one harmonious whole. See Fig. 3. So she came out also with a smart compact "go" about her, partly picked up from the "long boilers," which had that virtue, at least, that they were about the cleanest and simplest looking job ever made of a locomotive. The result quite satisfied me, and I cut off the drawing and took it to the office on Monday morning, where it was submitted to the usual criticism, and was at once approved in almost every particular; and I was instructed to go on with ordering boiler plates and working out details. This drawing I have, now faded with age, but the original, and it can be inspected and compared with the early tracings of the "Jenny," dated 1847, and with the engravings which appeared in THE ENGINEER on the 10th January, 1896, and after, and which are reproductions of old engravings from *The Practical Mechanic*, the tracings for which were furnished by Messrs. E. B. Wilson and Co. at the time; thus the originals are very old prints, and are authentic.

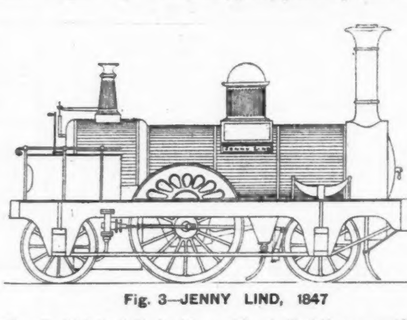

Fig. 3—JENNY LIND, 1847

Very soon the interest gathered around the new engine, she was so different from anything that was under construction in the works. Mr. Wilson was often at my board to see how matters progressed, but he had much higher and more profitable work to do than to design engines. Those who have raised the hue and cry on this subject might as well have said that he made his own balance sheets, but that was not the system at the Railway Foundry under his government; each department had its own work to do and did it, and did not interfere around, and in the establishment and organisation of the concern the Railway Foundry soon became, raising its power of production from ten to twelve engines per annum to a capacity of one engine a week, was a big thing in those days, and this was accomplished within a year; and beyond this work was found to keep the place fully going, and this, too, was no small matter. But Mr. Wilson's power of control over others, especially in a case of securing an order, was marvellous—it was magnetic. I was present at the settlement of the order for the ten big engines for the Manchester, Sheffield and Lincolnshire Railway, and often else I saw this.

Mr. Fenton also was often round, and left his impress on the engines as work went on. I had seen on the engines building at Railway Foundry when I first went there, the steam pressure raised from the usual 60 lb. to 90 lb., and I found this still further raised in the Brighton engine to 100 lb., and I, of course, adopted this pressure for the new engine, though the usual pressure around us was 80 lb. This Mr. Fenton, with his well-known tendency to go ahead, ordered to be lifted to 120 lb. And this, as a fact, was one of the main causes of the success of these engines. This feature, recognised and utilised by the next superintendent of the Brighton Company, Mr. J. C. Craven, enabled him with these comparatively small engines to run the Brighton trains quite up to the highest speeds then attained, and on, also, by far the lowest consumption of fuel burnt. I have an authorised copy of a coke list, soon after the Jenny Linds got fairly to work, where the lowest consumption on the list of main line engines was 16·75 lb. per mile, and the highest 19·47 lb.

The first engine was completed for trial in May, 1847, and was finished regardless of cost. The boiler and fire-box were lagged with polished mahogany, and bound with bright brass hoops and brass furnishings, the dome and safety-valve tops were bright copper, and there was other bright work about that made of her a very smart-looking engine.

The first run was made from Leeds to Wakefield and back, and was not accompanied either by Mr. Wilson or Mr. Fenton, only by us heads of departments—Willis and myself and others—and we had the bad luck nearly to fall in for a collision on the return.

Immediately after this the new erecting shop was completed, and was opened with a big banquet and a dance, and the next morning the first boiler was over a pit ready to begin work, and soon after the delivery of an engine a week began, and the rush came, every railway company wanting these engines, they became so immediately popular, as from the pressure carried they could both pull and run.

So I have shown that the origin of the Jenny Lind was no more an accident than was the introduction on our railways of the compound system, or any other great advance in railway practice, but the fulfilment of the need for an engine, both to pull and to run, and to do both economically, when locomotive practice, as THE ENGINEER said in that article, was in a very chaotic condition, and schemes of extraordinary design and daring were being brought out.

And to summarise, I have proved four things:—

First, that the "full statement" of an accident described as the origin of the Jenny Lind was not in Mr. Tomlinson's presidential address of 1890. Secondly, that the standard engines said to have been built by Messrs. E. B. Wilson and Co., at the Railway Foundry in 1846 could not have been built. Thirdly, that therefore the accident described could not have happened, as no Railway Foundry engines of that year had any outside bearings to twist off, so the Jenny Lind could not depend on that for her general design. Fourthly, that the drawing which settled the general design of the Jenny Lind was made as and where I have described.

As I have hinted, the Jenny Lind was not by any means the only interesting engine of the day brought out by Messrs. E. B. Wilson and Co., from Railway Foundry, in those early days of progress. Some of the early Cramptons, the Lablache, the Double Boiler, the Little Mails, and other engines built for higher pressures, and suggesting rapid advance in constructive design, with histories even more interesting from an experimental point of view, came out from Railway Foundry shortly after. DAVID JOY.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

IN finished iron the marked bar houses are this week fairly well situated for orders, and continue to quote the £7 basis. In merchant bar iron there is a steady inquiry going on, and quotations are £6 to £6 5s. The manufacturers of common bars are also in possession of some good orders at £5 5s. to £5 10s. Increased demand is registered for black sheets, and makers quote £6 10s. to £6 15s. for doubles. The hoop and tube strip manufacturers report a favourable amount of new business, and continue to realise £6 7s. 6d. There are fair inquiries for angles, and the quotation is £5 15s. Galvanised sheets are in good demand at £10 2s. 6d. to £10 5s. for 24 gauge at Liverpool.

Steel makers are doing a brisk trade at £4 5s. for Bessemer billets and blooms, but some North-county and Welsh steel may be had at £4 2s. 6d.; Siemens, £4 12s. 6d.; £5 12s. 6d. to £5 17s. 6d. for angles and boiler plates, £7 5s. to £7 10s. for sheets, and £5 15s. for bars.

The pig iron manufacturers are in receipt of moderate orders for forge, and a regular demand exists for foundry. Quotations are maintained at recent levels. Cold blast pig, 90s.; Staffordshire all-mine, 55s.; part mine, 40s. to 42s. 6d.; and 35s. 6d. for cinder. Northamptonshire forge is 39s. to 40s.; North Staffordshire and Derbyshire, 41s.; and Lincolnshire, 42s.

The tender of Mr. G. Law, of Kidderminster, has been accepted for the carrying out of the important sewage scheme recently determined upon by the Town Council of Shrewsbury. The following are the tenders sent in. They were as follows:—A. Krauss, Bristol, £26,747; H. Weldon, Birmingham, £34,412; C. Harris, Shrewsbury, £31,640; John Jackson, Plaistow, E., £30,000; Enoch Tempest, Rawtenstall, £27,987 3s.; A. Skellett, Manchester, £27,025; Geo. Law, Kidderminster, £22,978; Ed. Iles, Mitcham Common, £29,339; Bentley, Son, and Partington, Bury, £32,067 14s. 6d.; J. Mowlem and Co., London, £55,155; G. Bell, Tottenham, N., £28,960; Currall, Lewis, and Martin, Birmingham, £28,936 3s. 7d.; Jones and Fitzmaurice, Birmingham, £33,000; Jas. Dickson, St. Albans, £28,567; W. Cunliffe, Kingston-on-Thames, £24,998; G. Osenton, Westerham, £29,863; James Nuttall, Manchester, £29,444 9s.; and John Weston, Chester, £42,448.

The boom in cycle engineering continues unabated. Further additions are almost daily being made to the crop of new cycle tube and cycle companies which are just now constantly appearing in the Midlands, and which have now reached a total of seventeen since November. The total capital of the nine such companies floated since my last letter amounts to £1,164,000. Six of them have each a capital of £100,000, or more, and one is for a quarter of a million. Many establishments are working double shifts night and day, and are yet in arrear. All this means a correspondingly large demand for tube drawing and other sorts of machinery, and is looked upon consequently by the mechanical engineers of the district with the greatest satisfaction. As much as £15 15s. is being paid for Swedish steel blooms of best quality, or £3 15s. per ton more than last year. It is estimated that the American make of cycles for the current season up to July next will amount to 1,000,000 machines, and English steel tube is, it is believed, being used for about two-thirds of these. Tube prices are rising. Discounts a year ago in the Midlands were as much as 77 per cent.; to-day they vary from 57 to 35 per cent. Among the new companies announced during the past few days are the Coventry Cross Cycle Company, capital £100,000 (to acquire the business of Warman and Hazlewood); Premier Tube Company, capital £15,000 (to acquire the business of Mr. Alfred Smallwood, Premier Tube Mills, Birmingham); Auto Tube Company, £30,000 (to take over the business of C. Hudson and Collier, Seamless Tube Works, Ashton); Metallic Seamless Tube Company, £85,000 (to acquire the business of the Metallic Tube and Flask Company, Wiggin-street, Birmingham); Trent Cycle Company, £100,000 (to take over the business of the old company of the same name and its works at Long Eaton, Nottingham); the Endurance Tube and Engineering Company, £190,000 (to acquire the works and business of the Endurance Seamless Tube and Vial Company, of King's Norton, who put down an excellent plant about six months ago); the New Hudson Cycle Company, £20,000, Birmingham. In most of these cases considerable extensions of plant and machinery are contemplated.

An extraordinary general meeting of shareholders of the Coventry Machinists Company, Cheylesmore, Coventry, the parent company of cycle manufacturers, is to be held to consider an offer made by a syndicate for the purchase of the undertaking, with a view to its further development. The exact terms of the offer are not made known, but it is stated with some show of authority that the price will enable £20 to be paid for each share, which is of the nominal value of £4 10s. It is also stated that negotiations have been completed for the sale of the Premier Cycle Works, &c.—Messrs. Hillman, Herbert, and Cooper—for the sum of £450,000, and that negotiations are nearly completed for the sale of the Rudge-Whitworth Company. The Singer Company's purchase price is fixed at £750,000.

A syndicate of Canadian capitalists have offered to purchase the whole of the Birmingham tramways undertakings, and a somewhat similar scheme is also in hand with regard to the South Staffordshire tramways. The would-be purchasers are Mr. William MacKenzie, president of the Toronto Street Railway, and Mr. James Ross, managing director of the Montreal Street Railways. They propose to abolish steam and substitute electricity for some other power. The tramways directors, in a circular just issued to the shareholders, recommend the acceptance of this extraordinary offer. The present authorised capital is £300,000, and the number of shareholders is about 1500.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—The continued lull as regards new buying in the iron market here has necessarily a depressing tendency, and in some quarters there is an uneasy sort of feeling as to the possible course of prices, which is resulting in very low figures being quoted to effect clearances of iron already bought, whilst merchants and dealers are here and there showing a disposition to enter into speculative "bear" operations for forward delivery. The downward tendency in prices is still chiefly confined to pig iron, and is partly due to makers pressing for specifications from merchants and dealers who have overbought, and are consequently realising as best they can, rather than run the risk of low-priced contracts being cancelled. In the finished iron trade the position is also weak, but so far prices are generally being steadily maintained. The steel trade continues strong, and although merchants undersell, makers are apparently not at all influenced in their quotations, which continue firm at full rates.

Business on the Manchester Iron Market continues generally extremely slow, with prices steadily tending downwards, especially for pig iron. For local foundry brands makers hold firmly to late rates; in forge numbers there is nothing stirring to really test prices, but these could scarcely now be fully maintained. Lincolnshire makers have during the week been compelled to further give way in their list rates for forge iron, which is now quoted 40s. 6d., but foundry qualities remain at 43s.; Derbyshire foundry, however, is easier, and does not average above 45s. 6d. net, delivered Manchester. In outside brands there is some very low cutting on the part of merchants. Ordinary G.M.B. Middlesbrough has in some cases been obtainable at 45s. 4d. to 45s. 7d. net cash, delivered by rail Manchester, although makers do not quote under 46s. 4d., whilst the docks price is 44s. net cash. For Glengarnock the official quotations are 49s. 9d., delivered Ship Canal, Manchester, 48s. 6d. at Preston, and 47s. 6d. other Lancashire ports, but there are ready sellers in the market here at 9d. less, whilst Eglinton can be bought at 46s. to 46s. 3d. delivered ports, and 48s. 6d. delivered Dock Quays, Manchester.

Manufactured iron is without quotable change, except that one large firm, who, as I reported last week, have had to close a portion of their works on account of the falling off in shipping trade, are rather low sellers. New work generally is, however, not coming forward very freely, and forges are not so well employed as they have been. Quotations remain as given last week.

In the steel trade a strong tone is maintained, and although in raw and manufactured material merchants undersell, makers show no disposition to give way on their quoted rates. For hematite makers still quote 58s., less 2½, for No. 3 foundry, delivered Manchester, but merchants are sellers at 6d. to 9d. under this figure. A fair amount of activity is reported in some classes of manufactured goods, prices for which are hardening, £6 to £6 2s. 6d. being now quoted for bars, but steel boiler plates remain at £6 5s. to £6 7s. 6d., delivered in this district.

Activity continues to be fully maintained throughout the engineering industries of this district, all branches being well employed, and in most cases reporting new work coming forward freely. Fairly large orders are being booked by locomotive builders, and the Vulcan Foundry Co., Newton le Willows, has just secured an order for sixteen engines for the Eastern Bengal Railway, of the type recently illustrated in THE ENGINEER. The firm has also received another order from the North-Western Railway of India for twenty goods engines of a similar type to a number they have already in hand for the same company. The improvement recently reported in the boiler-making trade is also being fully sustained, and machine tool makers report a large weight of inquiry, with orders both for light and heavy machine tools coming forward freely, whilst stationary engine builders continue in the same satisfactory position that has been reported for some time past.

Visiting the Ordsal Works, Salford, of Messrs. Hulse and Co., this week, I had an opportunity of seeing an exceptionally massive and powerful vertical shaping and slotting machine they had just completed for dealing with the heaviest armour plates that are now being constructed. This machine, which weighs upwards of 120 tons, will admit 14ft. between the uprights, and has a table 17ft. in length, whilst the slotting stroke can cut through a thickness of 30in. A special feature of the machine is that it will slot at an angle of 45 deg. out of the vertical plane, either transversely or longitudinally. The tool slide is self-acting, and there are power motions for adjusting the table carrying the armour plates along the bed, and also for the swivelling slotting slide, whilst the feed is variable over a wide range. The firm had also in hand five large lathes, and several gun boring machines, which are to be driven electrically, with motors self-contained.

Mr. J. K. Broadbent, of Islington-square, Salford, has recently patented an improved forced draught arrangement for undergrate blowers, which is applicable to all classes of steam boiler furnaces. The arrangement consists essentially of a mouthpiece of trumpet form, which is supplied with a very small jet of steam, under one-sixteenth, which carries in a large quantity of air, and increases the draught through the fire bars. The steam which is used for producing the draught assists in keeping the bars cool, and, after passing over the fire, is finally converted into water gas and burned, thus giving back to the boiler the same amount of heat which was required to produce the steam, and the increased draught causes the fire to burn much brighter and clearer than would be the case with a defective draught through the fire. By this means the combustion in the furnace is rendered perfectly satisfactory, even where the chimney draught is defective, whilst another advantage is the great saving in the coal bill, as any inferior kind of fuel can be used where the Broadbent forced draught is applied. No special class of furnace bars are requisite to admit of the application of this arrangement, nor is it necessary to enclose the ashpits. The method is already in operation at a number of works in this district, and very satisfactory results have been obtained in the direction of increased steaming capacity.

The coal trade remains without improvement, and, in many cases, collieries are not working more than three to four days per week, whilst those which are kept going four to five days are, as a rule, putting into stock. For all descriptions of round coal, the demand continues only of very limited weight, and even in anticipation of the holiday stoppages of the pits, which, in most cases, will extend over a week, there is very little extra buying going on. The better qualities suitable for house fire consumption are without quotable change; but there is an easier tone in prices, and representatives of collieries are in most cases prepared with concessions to effect sales of any weight. Only in exceptional cases is best Wigan Arley fetching more than 9s. 6d.; with seconds qualities of Arley and Pemberton 4ft. averaging about 8s., and common house coal 6s. 6d. to 7s. at the pit mouth. Supplies of steam and forge coals continue largely in excess of requirements, and very low prices are ruling, good average qualities not fetching above 6s. per ton at the pit mouth. Engine fuel meets with a ready sale, with rather higher prices obtainable; but supplies are fairly plentiful, owing to increasing quantities coming in from other districts. At the pit best sorts average 4s. 3d. to 4s. 9d., and common slack from 3s. to 3s. 6d. per ton.

For shipment prices show no sign of any upward move, and steam coal, delivered Mersey ports, is still readily obtainable at 6s. 9d. to 7s. 3d. per ton.

Barrow.—The hematite pig iron trade has, so far as prices are concerned, shown a somewhat weaker tone this week, but this is accounted for by speculative reasons, and not by any falling off in the demand. Makers, in fact, are in daily receipt of inquiries for heavy forward deliveries. Some iron went into stock last week, delivery of which is not required for some time, and this influenced timid holders, who sold at 47s. 2d. net cash, buyers offering 47s. 1½d. The normal value of hematite pig iron is still quoted at 49s. to 50s. per ton, net f.o.b., but business is generally done at a shade over warrant prices. Stocks show an increase of 295 tons, and now represent 308,647 tons, or 19,472 tons increase since the beginning of the year.

Iron ore is selling well, and the native mines are well employed, and some recent discoveries of metal have led to a better prospect for the iron mining industry in the future. Prices show no change, native qualities being at 10s. per ton for ordinary sorts, and from 12s. 6d. to 14s. 6d. for best descriptions, net at mines. A steady business is doing in Spanish iron ore, many cargoes of which are imported weekly.

Steel makers are fully at work, and the demand for rails is especially active. Makers keep their mills regularly employed, and they have orders in hand which will maintain general activity for several months to come. The continuance of brisk trade is, in fact, assured for the year, not only in the rail, but in all other heavy branches of the trade. Prices are very steady, and there is an all-round fair margin of profit.

The only note of interest in reference to the shipbuilding and engineering trades is that H.M.S. Powerful, first-class cruiser of 14,200 tons, is ready to take her steam dock trials at Barrow next week. This monster cruiser, ordered January 1st, 1895, will be ready to hand over to the Admiralty some time during June.

In the coal and coke trades there is a brisk business, and the consumption is fuller than it has been for some time past, but prices are unchanged, though firm.

Shipping shows a marked improvement. During the week 9921 tons of pig iron and 17,931 tons of steel were exported from West Coast ports, as compared with 3125 tons of pig iron and 4389 tons of steel in the corresponding week of last year, an increase of 6796 tons of pig iron and 13,542 tons of steel. The aggregate shipments this year up to now represent 120,695 tons of pig iron and 177,200 tons of steel, as compared with 99,542 tons of pig iron and 131,556 tons of steel in the corresponding period of last year, making an increase of 21,153 tons of pig iron and of 45,644 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

CONSIDERING the state of the weather there is hardly any business doing in the house coal trade. The metropolis is taking but a limited quantity. Merchants refuse to purchase forward supplies, and while owners require only a small tonnage, and sea-borne coal is sold at very low rates, inland coalowners continue badly off for orders. Prices are at present very low, and purchasers in a position to place orders for fair tonnages obtain easy terms. Quotations remain about the same, and are not likely to be changed. Silkstone, best, is at 8s. 3d. to 9s.; ordinary, 6s. 9d.; Barnsley house, 7s. 3d. to 8s.; secondary sorts, 6s. 9d.; Flockton, 7s. to 7s. 6d.; and thin seam, 6s. per ton. There is an active demand for steam coal, the tonnage at present leaving the district being very considerable. A large quantity is going to Hull, and a similar remark applies to Grimsby. Everything points to a satisfactory export trade, so far as the local collieries are concerned. A moderate tonnage is being taken by the railway companies, and the general demand is fairly good. Heavy supplies are on the market, and the prices consequently are hardly equal to previous quotations. Barnsley hards are at 6s. 6d. to 7s. per ton; seconds from 6s. per ton. Gas coal is in moderate demand. Manufacturing fuel is fairly active, and values are fully maintained. Small nuts, 4s. 3d. to 5s. 3d. per ton; screened slack, 3s. 3d. per ton; pit slack, 2s. 6d. per ton; smudge, from 1s. to 1s. 6d. per ton. Coke is increasingly called for at from 8s. 6d. to 10s. 6d. per ton for ordinary sorts; best washed coke realising 12s. per ton. A considerable tonnage is being sent to Derbyshire and North Lincolnshire.

The demand for railway material, both on home and foreign account, has largely increased during the last four weeks. Most of the British companies had allowed their stores and stocks to get very low, and the sudden accession of better business put an end to the reluctance to give out orders for wagons, carriages, and other railway goods, both in the rolling stock and permanent way departments. A good deal of work will be found in the erection of the new locomotive shed for the Manchester, Sheffield, and Lincolnshire Railway at Woodburn junction, which is to accommodate over two hundred engines. This is one of the changes necessitated by the extension to London, the old place at Neepsend, west of Sheffield, being altogether inadequate for the increased requirements. All our makers of tires, axles, buffers, springs, &c., are full of work. There is also a good deal more doing in marine material, the specialities recently introduced being an increasing request for ocean-going steamers. The values of iron and steel have, of course, been affected by the betterment in trade. Lincolnshire forge iron is now at 39s. per ton; Bessemer billets, of special carbon, range from £5 12s. 6d. to £6; Siemens-Martin steel, from £7 to £10 10s.; bar iron, £5 10s. at makers' works; hematite irons, 54s. 6d. to 57s. 6d., delivered in Sheffield.

The extraordinary demand for bicycle steel already noted is more than maintained, with the usual result of causing values to stiffen. Some of our manufacturers, believing that this department is certain to furnish abundant work for a considerable time, have laid themselves out to meet the pressure. Should next season's demand be at all equal to what it has been during the last month or two, the extended arrangements for coping with it will enable the wants of Coventry, Wolverhampton, Beeston, and other parts to be more rapidly met. The local firms who recently commenced the production of bicycles in Sheffield—which, it is held here, really ought to have been the home of the cycle industry—are doing very well, their make steadily advancing on the market.

In the lighter trades of the city there is a gratifying improvement reported from the Australasian markets, and much more is doing with South America, the better understanding between Argentina and Peru being a favourable factor in the commercial situation. On the other hand, there is less doing in cutlery for the United States. The leading houses in cutlery, electro-plate, and silver are generally well employed, but the lesser firms could do with more business. The order for cutlery, electro, &c., for the Hotel Cecil—said to be the largest of its kind yet given out—has been divided between Birmingham and Sheffield, Birmingham taking the largest share.

Much better business is reported with Turkey, Egypt, and the Soudan. The Turkish market has latterly yielded some very good orders. The occupation of Egypt by England has led to more trade with the home country, and the quality of the goods ordered has also improved. It is hoped that the operations now proceeding will lead to the reopening of the Soudan, which was closed after the retreat following the former expedition. If the country is again opened to Sheffield goods, the benefit felt here will be most acceptable.

The *Sheffield Daily Telegraph* has initiated a vigorous campaign against excessive smoke. After a series of special articles by an engineering expert, showing that smoke abatement was not only possible, but was already being carried out most satisfactorily in many of the large works, the proprietors of that journal established a Pure Air Fund, heading the subscriptions with £50, the object being to undertake firm and impartial prosecution of all who unnecessarily pollute the air. The intention is to join the Manchester Smoke Abatement League, which is now on a material basis, and undertakes prosecutions in any part of the country.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE week opened badly, business being very languid in nearly all branches of the iron and steel industries in this district; but the engineers' strike having ended, the stumbling block in the way of local trade was removed on Tuesday, and the market at once showed improvement, and consumers who have been holding back, owing to the uncertainty, are now manifesting a disposition to operate again. The strike only lasted a fortnight; and fortunately was confined to narrower proportions than were at first threatened, only the men on Tees-side and the Hartlepools coming out. They have gained their point, however, and work was resumed at some establishments on Wednesday, while at other places operations will not be re-commenced until after the Whitsuntide holidays. The dispute, it will be remembered, arose because the employers in the engineering establishments in the Stockton district intimated that they could not see their way to give, in September, the full 1s. per week advance to such members of the Engineers' Society as were receiving less than 30s. per week. When in March it was agreed to give this second 1s. per week advance to the members of the Amalgamated Society of Engineers, the employers were not aware that any of them were being paid less than 30s. per week; they did not know that the constitution of the Society had been altered so as to admit unskilled men, such as machinemen, planers, &c., and they thus promised the advance to men of this class under a misapprehension. In all other departments they had arranged that the men earning less than 30s. per week should have 1s. advance early in April, but only 6d. advance in September, instead of 1s. to be paid to the more skilled men. This was only just seeing that the wages of such men were not reduced to the same extent as those earning over 30s. a week. The engineers at Stockton objected and struck work, refusing the offer of the employers to submit the dispute to arbitration, as they said there was nothing to arbitrate upon. They had promised all the members of the Society, without distinction, 1s. per week advance, and they would hold them to that promise. They contended for the literal carrying out of the agreement. The Middlesbrough men came out in support of Stockton, and afterwards the Hartlepool engineers, after the masters resolved to discharge 25 per cent. of the men weekly. On Monday and Tuesday conferences between the employers and the representatives of the men took place, and on the latter day the difficulty was removed by the masters agreeing to carry out the arrangement made in March literally, paying every member of the Society the 1s. in September whatever his rate of remuneration. The actual amount in dispute was very small, there being really very few men in the Amalgamated Society that are receiving less than 30s. per week, but the question was fought as a matter of principle. Certainly a large amount of money has been sacrificed in support of it, but now that they know of the alteration in the constitution of the Engineers' Society the employers can guard against a similar arrangement in future agreements.

A stronger pig iron market has been shown since Tuesday, inquiries have increased, and sales have become more numerous, but not till after the Whitsuntide holidays is anything of importance likely to be done. Nevertheless, the outlook may be described as more satisfactory, though a time is at hand when business is often slack, for there is generally only a small amount of buying in June and July. Probably there may not be anything approaching activity until the autumn demand sets in in August, and consumers are not in any hurry to operate. Exports of pig iron, so far this month, from the Cleveland district, have been good, though they fall short of those of April, and as the local consumption will be curtailed on account of the holidays, it is probable that the decrease in the stock of Cleveland pig iron will be very small, if there is not an increase. Last month, with a larger shipment, the decrease was only 5558 tons, and very little has been done to reduce the production of Cleveland pig iron this month. It would be well if some of the makers would blow out, say, three or four furnaces; the production would then be brought below the consumption over the quiet summer months, and the market would be considerably strengthened. The exports of pig iron from the Cleveland district this month up to Wednesday night were 63,243 tons, as compared with 68,304 tons in April, and 64,899 tons in May, 1895, to 20th. The stock of Cleveland pig iron in Connal's warrant stores on Wednesday night was 197,603 tons, or 3847 tons increase this month, the bulk of the increase accumulating in the early part of the month, as very little has been added during the past week.

Quotations for pig iron have been somewhat stiffer this week. No. 3 Cleveland pig iron has been obtainable at 37s. 3d. per ton for prompt f.o.b. delivery, both from makers and merchants, but since the engineers' settlement all the sellers have put up their rate to 37s. 6d., and some makers will not take less than 38s. There was, early in the week, some business at 37s. 6d. for June deliveries, but more than that is asked now. Cleveland warrants have been quoted this week as low as 37s. 1d. cash, but on Tuesday they rose to 37s. 3½d, and on Wednesday the influence of the termination of the strike making itself felt there was a further rise to 37s. 9d. No. 1 Cleveland pig prices have ranged between 38s. 3d. and 39s., the general quotation having been 38s. 6d. No. 4 Cleveland foundry pig iron is at 36s. 9d., and grey forge at 36s. 3d., but business was done at less early in the week. Mixed numbers of Cleveland hematite pig iron have been sold at 45s. 9d., but 46s. is generally quoted, which is considerably more than is being offered for hematite warrants, but practically no one cares to buy the latter, as they are not sure of the brand that will be supplied to them when they purchase warrants, and they may get a brand which they do not care for. Rubio ore is at 12s. 7½d. per ton, delivered at wharves on the Tees.

Except for rails, the demand for finished iron and steel has become slack, and prices are 2s. 6d. per ton easier than last week. Most manufacturers, however, are still well supplied with orders, and works are regularly employed. There is great activity at the rail mills, and makers have all they can do to keep up with the orders. For heavy steel rails they quote £4 10s. per ton at works, and this they have been able to realise. The demand for plates, angles, and bars is quieter than for some time past. Steel ship-plates are reduced to £5; steel ship angles to £4 17s. 6d.; iron ship-plates to £4 17s. 6d.; iron angles to £4 15s.; common iron bars to £4 17s. 6d.; and best bars to £5 7s. 6d., all less 2½ per cent. and f.o.t. Puddled bars are at £3 5s. net at works.

Shipbuilders are very well occupied, and appear to be booking orders as quickly as contracts are completed. Sir Raylton Dixon and Co., Middlesbrough, are building a series of steel towing vessels, which are intended for a new method of coal-carrying across the North Sea. The vessels are for the Schupvart Steenkolen Maatschappij, of Rotterdam, and the first was launched a few days ago. It is 170ft. long, 32ft. beam, and 13ft. 7in. deep, and the deadweight cargo capacity is 1000 tons. These vessels will be towed by screw colliers, which themselves will carry 1700 tons of coal between the coal ports of the North of England and Rotterdam. They will be fitted with sails and heavy chains and anchors, so as to be quite independent and seaworthy, should the steamers have to cast them off at any time through stress of weather. Sir R. Dixon and Co. have secured an order for a steamer of 5000 tons carrying capacity, for Messrs. Cory and Sons, of London, and Messrs. Short Brothers, of Sunderland, will build a large steamer for the Nitrate Producers Co., and similar to the Juanita North launched for the same owners a few days ago. The Tyne Pontoon Company is enlarging its dry dock at Wallsend, and when completed, it is said, will be the largest on the North-East Coast. It will be 550ft. long, and have a depth of 26ft. of water on the sill. Messrs. R. Cragg and Sons a few days ago launched the first vessel which they have built at their new yard at Middlesbrough.

The executive council of the United Society of Boilermakers and Iron Shipbuilders have decided to present to Mr. Robert Knight a memento of the esteem and goodwill of the members, and are raising voluntary subscriptions for that purpose. The proposal is warmly supported in all parts of the country. Mr. Knight has been twenty-five years the secretary of the organisation, and is as highly esteemed by the employers as by the men themselves. If all trades union officials were as reasonable as Mr. Knight there would be few strikes. Mr. Knight has been long an ardent advocate of arbitration and conciliation in trade disputes.

The first sod of the North Sunderland Railway, which will run from the Chathill station on the North-Eastern between Newcastle and Berwick to the place named, was cut on the 14th inst.

On Tuesday electric trams commenced to run at Hartlepool, the overhead trolly system being adopted.

The coal trade is improving, more especially the steam coal branch, and the Northumberland pits are profiting the most by this. The price of best steam coal is stiffer, 8s. 3d. per ton f.o.b. being the figure. It is to be regretted that the Durham miners continue to display such hostility to the Conciliation Board, in spite of the good advice given to them by their Executive Council. The second ballot has been as adverse as the first, and the Board will, therefore, come to an end on August 4th. Only 17,556 voted in favour of the continuation of the Board, 33,114 voted against, and 13,631 were neutral, but all the collieries did not vote. The Earl of Durham has concluded the agreement to transfer all his collieries to Messrs. James Joicey and Co., of Newcastle-on-Tyne, who are already amongst the largest colliery proprietors in Durham. The Earl's collieries are fourteen in number, produce over 2,000,000 tons of coal per annum, of gas, house, and steam coal, and employ 8000 men and boys. Included in the purchase are the Earl's nineteen steam colliers, the railways and railway plant connected with the collieries, thirty locomotives, and the coal shipping station at Sunderland. Messrs. Joicey previously had 13 collieries, 300 coke ovens, and 30 steam colliers. Now, therefore, they will own twenty-seven of the best collieries in Durham, with a production of 4,500,000 tons per annum, and they will own forty-nine steam colliers. They will thus be the largest firm of coalowners in this country, if not in the world.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE has been a firmer feeling in the iron market during the past week. An impression has become general that the dispute in the engineering branch of the shipbuilding trade is likely to be arranged without resort to a strike, and this has had a favourable effect. Consumers are also found to have been purchasing more freely, while "bears" are reported to have been covering their over-sales. All this has tended to strengthen the tone of business, and to prevent a decline in prices. Indeed, some kinds of iron have been selling at a little more money.

In the warrant market there was a considerable business early in the week, mainly between dealers, the public holding aloof from investment in iron. At the same time, there is a pretty general belief among those most intimately acquainted with the trade, that prices are likely to be well maintained, so long as the manufacturing branches continue busy. Business was done in Scotch warrants from 45s. 11d. to 46s. 3d. cash, and 46s. 2½d. to 46s. 4½d. one month, the quantity of iron changing hands being considerable. In Cleveland warrants business was quiet, transactions taking place from 37s. 1d. to 37s. 3d. cash, and at 37s. 5d. one month. For hematite warrants there was only a limited demand, and that was mainly for delivery a month hence. Cumberland warrants sold at 47s. to 47s. 1d. cash, and 47s. 2d. to 47s. 4½d. one month.

The output of Scotch pig iron is fully maintained. Indeed, since last report an additional furnace has been put in blast. There are now 40 furnaces producing ordinary, 30 hematite, and three basic iron, the total of 82 comparing with 77 at this time last year.

Prices of makers' iron have been steady:—Govan, Monkland and Carnbroe, Nos. 1, are quoted 47s.; Nos. 3, 45s. 6d.; Clyde, No. 1, 50s.; No. 3, 47s.; Summerlee, Calder, and Gartsherrie, Nos. 1, 50s. 6d.; Nos. 3, 48s.; Coltness, No. 1. 53s.; No. 3, 48s. 6d.; Glengarnock at Ardrossan, No. 1, 50s.; No. 3, 46s.; Eglinton, No. 1, 47s.; No. 3, 45s.; Dalmellington at Ayr, No. 1, 46s. 6d.; No. 3, 44s. 6d.; Shotts at Leith, No. 1, 52s.; No. 3, 48s. 6d.; Carron at Grangemouth, No. 1, 52s. 6d.; No. 3, 48s. 6d.

Stocks of pig iron in the public stores in Glasgow remain practically as they were a week ago, the total being about 73,000 tons larger than at this time last year.

The pig iron shipments are light, amounting to only 4690 tons, against 7848 in the corresponding week of last year. There is no improvement in the inquiry from abroad, but the home consumption of pig iron just now is fortunately so good that the smallness of the reports is less felt than it would be in other circumstances.

In the finished iron department a steady business is being done, with scarcely any change in prices. Sheets are in good request, and the tube makers are for the most part actively employed.

Locomotive engineers are full of work and marine engineers are fairly supplied, while founders and ironworkers generally are obtaining a fair market for their goods.

All departments of the steel trade are busy, and makers of shipbuilding material are taking a less serious and apprehensive view of the labour question than they did a week or two ago.

The coal trade does not exhibit any change for the better. The shipment from Scottish ports in the past week amounted to 153,733 tons, against 182,105 in the preceding week, and 167,501 in the corresponding week of last year. Prices f.o.b. at Glasgow are, for main coal, 5s. 9d.; splint, 6s. 3d. to 6s. 6d.; ell, 6s. 3d. to 6s. 9d.; and steam, 7s. 6d. per ton.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

EXPECTATIONS at Cardiff last week were not fully realised as to the shipments of coal, tonnage coming in rather slowly, but as it was the export of the week exceeded 36,000 tons, and several notable cargoes were included. This week one steamer left Cardiff for Batavia with 5000 tons, and several large ones for Malta, Monte Video, &c.

Swansea coal business last week was very slack, nothing like the average being reached, and Newport totals were under the mark.

These matters are only regarded as temporary, and good business is anticipated generally, in front of the public holidays, after which some degree of lull is tolerably certain. On 'Change, Cardiff, this week, the tendency has not been to book freely, as a hope of better prices prevails, and a good sign is visible that best seconds are in capital demand. More business is being done in dry coals, and the coal of the Monmouthshire valleys continues to be inquired after. The energy shown by railway speculators in pressing forward their schemes to get into these valleys, indicates a hopeful view of the future of that great coal district. The Tredegar and Rhymney Iron and Coal Companies, with their respective fine areas of excellent coal, may be expected soon to figure even more extensively than at present.

In the Glamorganshire districts Dowlais-Cardiff is beginning to figure, and the character of the coal is well sampled at the Cardiff Exhibition, where it comes in for close scrutiny at the hands of experts.

I see that a contract for 45,000 tons of South Wales coal for the Portuguese Railway Company has been secured by O. Herold and Co., of Lisbon. The Government of Surinam figures also for 2000 tons of Cardiff steam coal. Swansea continues its despatch of anthracite to the States, but last week it was under 2500 tons.

A slight improvement has begun to characterise the Rhondda Valley output, where, at the upper part in particular, there has not been the weakness which has characterised the lower districts. Ynysyfero is working regularly, but at the Bute trade is slack, and the dispute at the Bwllfa, which is one of the Ocean collieries, remains unsettled. The stoppage of that colliery and a part of the Ton pit is estimated to have been a loss to the district of £80,000. There is a dispute also on at the Mardy, Rhondda Fach, and a large number of working places have been stopped in consequence of the colliers refusing to do certain work at the rates offered. There is also a fear of a rupture at the Tylorstown collieries, if the management presses its contention about ripping the top without powder. My final item of labour difficulties is the Plymouth arbitration, which is to be given at the end of the week.

One of the events of the week at the docks, Cardiff, has been the presence of the twin screw steamer America, one of the finest ships owned by the West India and Pacific Steamship Company, Liverpool. She is in the Roath Basin, taking in 3500 tons bunker coal, and will proceed to Cape Town *viâ* New York. Her dimensions are interesting:—476ft. long, 55ft. beam, 40ft. depth, net register, 5407 tons; carrying capacity, 12,000 tons. Bunkers supplied by the Powell Duffryn Co.

Mid-week coal prices Exchange, Cardiff, were as follows:—Best steam coal, 10s. to 10s. 3d.; best seconds, 9s. 9d. to 10s.; ordinary seconds, 9s. 3d. to 9s. 6d.; dry coal, 8s. 7½d. to 9s. Monmouthshire coal as follows:—Western Valley, 8s. 3d. to 8s. 6d.; Eastern Valley, 7s. 9d. to 8s. House coal continues dull. Some of the weather prophets say that a slight improvement in price is likely before the really summer weather sets in, as some continuance of rain and colder weather at Whitsuntide is likely. Prices remain, subject to special arrangement, best household, 9s. 9d. to 10s. 3d.; No. 3 Rhondda, 9s. 6d.; brush, 7s. 9d. to 8s.; small, 6s. 3d. to 6s. 6d.; No. 2 Rhondda, 7s. 6d. to 7s. 9d.; through, 6s. to 6s. 3d.; small, 4s. 3d. to 4s. 6d.

Swansea coal prices are:—Anthracite, best, 11s. to 11s. 6d.; seconds, 9s. to 10s.; ordinary, 8s. to 8s. 9d.; culm, 4s. to 4s. 6d.; steam, 9s. to 10s.; seconds, 8s. 3d. to 9s.; No. 3 Rhondda, 9s. 6d. to 10s.; No. 2, 8s. 6d. to 9s. 6d.

Coke at Cardiff is in good demand. Furnace, 13s. to 14s. 9d.; foundry, 15s. 6d. to 16s. 6d.; special, 19s. 6d. Patent fuel, Cardiff and Swansea, is in moderate demand at last prices.

Pitwood at Cardiff has experienced a slight relapse, and prices are about 1½d. less than at the beginning of the week.

In iron and steel a fair amount of business is being done, and works in the Swansea district are busy. A moderate make is going on at Blaenavon and Dowlais, and Cyfarthfa is busier with steel bar and crop ends, and its revived steel rail industry.

I note that pig iron is coming in extensively from Millom and Middlesbrough, Swansea receiving 800 tons last week. Cargoes of ore, too, are numerous to Blaenavon, Dowlais, Cyfarthfa, Ebbw Vale, and Swansea. The last-named received 2000 tons last week. Swansea Hematite and the Newport Patent Nut and Bolt Company figure well.

Briton Ferry Ironworks are arranging for a new movement, calculated, it is thought, to affect foreign competition. This is to run steel ingots into moulds fresh from the blast furnaces, thus obviating re-smelting. This is expected to lessen considerably the cost of production. A good deal of pig iron is being turned out at these works, and it is satisfactory to note that the demand is in excess of supply.

In tin-plate prices are slightly better, and more work is being turned out. If this should be followed by an increased demand, the hopes of tin-plate manufacturers and men would soon be revived. Unfortunately, though some small cases of improvement are recorded, the general character of the trade remains much about the same, and will continue until wages have been reduced to a point enabling manufacturers to turn out plates without loss, and to compete.

Taking a survey over the district, I find that the Western Tin-plate Works Llanelly will start in a few days, on a 15 per cent. reduction, for six months. These works have been idle ten weeks. The Ashburnham men stopped on Saturday, but resumed for a week on the 15 per cent. reduction. At Pontardulais the Teilo, Cambrian, and Clayton, and also the Glamorgan, are working at the same rate. This limit seems to hit the mark, and it is expected that all works now going at higher figures will have to adopt the same.

At the Villers Tin-plate Works on Saturday Messrs. Davy, Sims, and Taylor, directors, who had resigned, were unanimously re-elected.

Reports from the Exchange, Swansea, record a large attendance of members this week to hear Mr. Stanley's speech on opening out Africa to the tin-plate industry. This speech may be briefly summarised as an able investigation into the decline of the tin-plate trade, coupled with promptings to the Welsh to emulate Germany in its canvassing the world for business. Africa, he cogently showed, would be a grand market.

Iron and steel quotations this week are as follows:—Glasgow pig, 46s. 0½d.; Middlesbrough, No. 3, 37s. 2d.; hematite, 44s. 6½d.; Welsh bars from £5 10s. Iron plates, £6 15s. to £6 17s.; steel, £6 10s. to £6 12s. 6d.; Bessemer steel bars, £3 17s. 6d.; Siemens, £3 18s. Steel rails, heavy, £4 10s. to £4 12s. 6d.; light, £4 15s. to £5 5s. Tin-plates: Bessemer steel cokes, 9s. to 9s. 3d.; Siemens, 9s. 3d.; ternes, per double box, 16s. to 17s. 6d.; best charcoal, 12s. 6d. to 12s. 9d. Block tin, £60 6s. 3d. to £60 7s. 6d

The water supply of various districts in Wales is meeting with close attention, and the public interest in this has been increased of late, on account of the extraordinary dryness of the season. At Llanelly it was reported last week that the reservoir was failing rapidly, a million gallons a day going to waste. Stringent measures were adopted. At Merthyr the new reservoir is now being formed, and is to be pressed forward. Llanidloes is going in for a water-supply. The London scheme for acquiring a great watershed in Wales is again to the front. Mr. J. A. B. Williams, who engineered the Cardiff scheme at Taff Vaur, is in consultation; and Mr. R. Middleton, of London, an engineer of eminence, has the affair well in hand. A few figures will show the vastness of the scheme. The estimated expenditure is 10 millions sterling. It is proposed that the head reservoir shall be on the Usk, near Trecastle, and to contain 4,538,000,000 gallons. The average of the gathering grounds is about 122 square miles, namely, 61 square miles in the Usk Valley, 18 in the Irfon Valley, and 43 in the Towy Valley. Welsh opposition threatens to be strong. One of the objections named is a practical one, namely, that Wales will urgently need its own water sheds. Another is one of sentiment, that the London scheme will obliterate a number of places associated with the events of past history, and the lives of memorable men.

Lord Clinton's Committee of the House of Lords, which has kept the coal and railway works of Wales lately pleasantly exercised, with alternate winnings of the Bute, Barry, and Taff Vale companies, has decided that clause 25 of the Taff Vale Bill, by which promoters sought to be relieved of certain obligations under which they render services at the Bute Docks, should be struck out.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

ACTIVITY in the various departments of the iron and steel trade has further increased, and there was also a marked improvement to be perceived in the tendency of quotations. Exports have been, on the whole, pretty heavy during the past week.

Silesian iron masters describe the business doing as altogether satisfactory. The different branches are all very busy, numerous orders coming in almost daily, which, though often of small weight, will keep the establishments briskly engaged for a considerable time. Prices are firm and paying, generally; further advances are not expected to take place in the immediate future. Production of pig iron in Silesia was, for the first quarter of present year, 145,232 tons, against 125,496 tons for the corresponding period the year before.

In Austria-Hungary the market for iron and steel continues brisk, inland consumption being pretty large. Offers from foreign houses have of late been a trifle less numerous, and this is having a good influence on prices. Sheets have already been slightly raised, and for several other articles an official advance is expected during this week or the next. The railway and engineering departments are likely to be busily occupied for some time ahead. List rates are: For common forge pig, 45 to 46 fl.; grey do., 47 to 51 fl.; Bessemer, 49 to 51 fl.; ingots, 76 to 80 fl.; Styrian bars, 115 to 120 fl.; girders, 107 to 110 fl.; heavy plates, 180 fl.; tank do., 135 fl.; sheets, 140 to 160 fl.; galvanised sheets, 205 fl.; all per ton free Vienna. Tin sheets cost 26 fl. per box. Austro-Hungarian export trade has been, all things considered, rather dull for some time past. In the export trade to Roumania, for instance, Austria-Hungary only took a small part, principal supplies coming from England, Germany, and Belgium. This is due to the unfavourable condition of prices. Basis quotation for Silesian bars was, for 1895, M. 100 p.t., free Gleiwitz, while Styrian bars stood at 100 fl. p.t., free Donawitz. In 1895 one of the leading Silesian firms sent more than 2000 t. plates to Roumania at M. 221 p.t., free Galatz, while the price for Styrian plates would have been M. 240 p.t., free Galatz.

Concerning the French iron market, extremely good accounts are given. A very lively business is doing in the raw and in the finished iron and steel trade, and prospects for further employment are bright, producers having their books well filled with orders for home and for foreign consumption. Quotations are favourable on the whole. Merchant bars stand on 145f. p.t. free at works, and when orders for immediate delivery are in question, M. 150 p.t. is generally asked. In the Haute-Marne the works have been vigorously engaged since March, and though output is large, makers are hardly able to meet the active demand that has of late been experienced. In Paris prices are steadily maintained on 155f. p.t. for merchant bars, and 165f. p.t. for girders, the latter being in particularly good request on account of the briskness in the building line. In the Departement Nord there has been quite a "rush" on the iron market. Export prices have again shown a rising tendency; basis quotation for bars is at present 145f. p.t., but 150f. p.t. will soon be asked and obtained. A fair number of orders has been secured at the construction shops. In the Maas and Moselle district pig iron is exceedingly scarce, stocks, which were rather low when the revival set in, having now almost entirely disappeared. Forge pig has been offered at 50f. p.t., foundry No. 3 fetching 60f. p.t. Quotations for nearly all articles of finished iron are exceedingly firm.

On the Belgian iron market a fair weight of business continues to be reported, and prices are moving upwards. Export orders have been pretty plentiful.

Increasing animation is reported in the Rhenish-Westphalian iron industry. The works are now all fully employed, and have excellent prospects. Stocks are very low, as the iron produced goes into immediate consumption, and the fact that makers have in several instances refused to accept orders at long terms of delivery, shows that work is plentiful.

Current list rates are, on the whole, satisfactory, leaving a fair profit; further advances in quotations will most likely take place in June or July. There is nothing of special interest to be reported with regard to the pig iron trade. All through last week much life has been stirring, and the different sorts meet with a very good demand at firm prices. Export orders, though increasing in weight and in number, have still to be accepted at comparatively low figures. The malleable iron market shows a bright physiognomy; the occupation at the mills and foundries is as good as can be, and there is a strong inclination on the part of makers to practice a certain reserve with regard to the booking of fresh work, some of the mills finding it almost impossible to execute the orders already booked within the time stipulated. At a meeting held on the 9th inst. the Rhenish-Westphalian rolling mills agreed to raise bars M. 2·50 p.t.; at the same time the Convention of Rolling Mills was prolonged till 1st of May, 1897. The building line is unusually active, and at date structural ironwork is in very brisk request; but in the matter of prices there is not much alteration, only a considerable stiffness is noticeable.

Producers of plates and sheets are well off for contracts, and the indications are all in the direction of a further improvement. Here and there rather more business is reported to be stirring in the wire trade, the steadily rising demand on foreign account being likely to improve the condition of prices, which are very low at present. Rivets sell briskly at firm quotations. The railway and engineering industries show improvement in that the works are more fully employed, but, unfortunately, the contracts in many instances have to be taken at prices that leave only the smallest profit, so keen is competition, both foreign and inland. The situation of the tube mills has perceptibly improved, and stocks are decreasing.

Output of coal in the Saar districts was, for April of present year, 467,200 t. against 40,718 t. for the same month last year: in Silesia 1,080,870 t. were produced, against 922,050 t.; in the Ruhr district 2,885,820 t. against 2,630,100 t., and in the three districts together 4,433,890 t., against 3,959,330 t. during the same month in 1895. Total output of coal during the first four months of the present year was in the Saar district 1,937,270 t., against 1,690,270 t.; in Silesia, 4,572,340 t., against 4,039,160 t; in the Ruhr district, 12,003,950 t., against 10,974,200 t., which shows an increase of 14·7f. per cent. for the Saar district, 13·6 per cent. for Silesia, and 10·3 per cent. for the Ruhr district, against the same period in the previous year.

Production of brown coal in Prussia is stated to have been 5,424,171 t. during the first quarter of present year, increase against the same period last year amounting to 407,844 t.; consumption was 4,369,408 t., or 529,817 t. more than during the first quarter in 1895. The number of men employed was 31,019, or 1305 more than during the corresponding period in 1895.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

GOOD attendance on 'Change. There is a fair demand for steam coal, and prices remain without any change. House coal shipments are good, with prices steady. Tin-plates in improved demand. The iron and steel works are fully employed.

Coal: Best steam, 8s. 3d. to 9s. 6d.; seconds, 7s. 9d. to 8s.; house coal, best, 10s.; dock screenings, 5s.; colliery small, 4s. 3d. to 4s. 9d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 46s. 6d.; hematite warrants, 47s. 5d. f.o.b. Cumberland; Middlesbrough No. 3, 37s. 5d. prompt; Middlesbrough hematite, 45s. 1d. Iron ore: Rubio, 12s.; Tafna, 11s. 3d. Steel: Rails, heavy sections, £4 12s. 6d.; light ditto, £5 f.o.b.; Bessemer steel tin-plate bars, £4; Siemens' tin-plate bars, best, £4 7s. 6d.; all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel, coke, 9s. to 9s. 3d.; Siemens, coke finish, 9s. 3d. to 9s. 6d.; ternes, per double box, 28 by 20 C, 18s. 6d. to 20s. Pitwood: 15s. 3d. to 15s. 6d. London Exchange Telegram: Copper, £46 12s. 6d.; Straits tin, £60 10s. Freights are firm, bot home and outwards

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, May 14th.

THE industrial situation is governed to-day by the same causes which existed three months ago. Mills are generally working to two-thirds capacity, excepting in the Pittsburgh district, where there is greater activity than elsewhere. As a result of the recent steel billet combination, certain concerns are considering the advisability of selling their allotment to the Carnegie people. There are possibilities behind this talked-of purchase of allotments—viz., the control of the steel works themselves by the Carnegie interests. The spirit of combination is rife. Manufacturers are huddling together in and with agreements which are intended substantially to keep prices above the level which competition would naturally determine. The railroads are neither building nor buying up to their average. The plate and structural mills are in sight of a vast amount of work, and it is likely to show itself in a few weeks. There is a greater abundance of engine building and shop work, of equipment and tool work, and of pipe line work. Contractors and engineers have specifications pigeon-holed for a great deal of new summer and autumn work, and manufacturers discount it, anticipating harder prices during the midsummer months. The protection cyclone that is sweeping over the country represents the accumulated indignation of the people over four years of free trade, or the closest approach to it we have had. Prices for almost all commodities are lower than for months. The banks are well supplied with money. Gold exports are large, and business men and bankers are anxiously awaiting the announcement in favour of an unequivocal gold basis at the St. Louis presidential convention to be held June 16th to 20th.

LAUNCHES AND TRIAL TRIPS.

On Thursday, 14th inst., Messrs. Lobnitz and Co. launched from their yard at Renfrew a powerful screw steamer for the United Steamship Company, of Copenhagen. The vessel is built under special survey of Bureau Veritas, and has large accommodation for first-class passengers and emigrants. The owners were represented by Mr. L. C. Caspersen, superintending engineer, under whose supervision the vessel has been built, assisted by Captain Thomsen and Mr. Fricke. On leaving the ways she was named N. J. Fjord by Mrs. Morris, of Ramsey Lodge, Trinity.

On Thursday, the 14th inst., the Tyne Iron Shipbuilding Company, Willington Quay-on-Tyne, launched a large steamer to carry oil in bulk, which has been built to the order of Messrs. Hunting and Son, of Newcastle-on-Tyne. The vessel is of the following dimensions:—Length, 356ft.; breadth, 47ft.; depth, 30ft. 3in. To class 100 A1 at Lloyd's on the spar deck principle for carrying petroleum in bulk, and is to have engines with cylinders 27in., 44in., 77in., by 48in. stroke. These will be supplied by the Wallsend Slipway and Engineering Co., of Wallsend-on-Tyne. Her outfit includes the very latest developments and appliances for the trade that she is intended to be engaged in. The sub-division of the tanks is in accordance with the requirements for carrying oil in bulk through the Suez Canal. On leaving the ways the vessel was named the Oilfield by Miss Arthur, of Glenariff, London.

On the 14th inst. Messrs. Ropner and Son, of Stockton, launched a steel screw steamer of the following dimensions, viz.: — Length between perpendiculars, 270ft.; breadth, 39ft. 6in.; moulded depth, 17ft. 6in.; which they have built for a West Hartlepool firm. The steamer is built off the part awning decked rule, having poop and raised quarter deck, her deadweight carrying capacity being 2600 tons on 16½ft. The saloon and cabins for the captain and officers are fitted in the poop, whilst the engineers are accommodated in iron houses placed on the awning deck near the entrance to engine-room. She is built on the web frame principle, leaving the holds entirely clear for cargo, and carries her water ballast in a cellular bottom and in the after peak; all labour-saving appliances are fitted for the economical working of the steamer, and also for the expeditious loading and unloading of cargoes. She has steam steering gear amidships and screw gear aft, four powerful steam winches, two large donkey boilers working at the same pressure as the main boilers, patent windlass, stockless anchors, &c. The engines will work up to about 700 effective horse-power, and are by Messrs. Blair and Co., having cylinders 19½in., 32½in., and 52½in. by 36in. stroke, steam being supplied by two large steel boilers working at 160 lb. pressure. The steamer was named Ashby by Mrs. J. W. Ropner, of West Hartlepool.

On Thursday, May 14th, Messrs. Furness, Withy and Co. launched from their yard, at Hartlepool, a large steel screw steamer, built to the order of Messrs. The Thompson Steam Shipping Company, Sunderland. She is a fine type of a modern cargo boat, measuring over 320ft. in length, and built throughout of Siemens-Martin steel, with a large measurement and deadweight capacity, and built to the highest class at British Corporation. The vessel is of the single deck type with poop bridge and top-gallant forecastle. The holds are fitted with iron grain divisions, and all decks, deck erections, skylights, bulwarks, bulkheads, &c., are constructed of steel and iron. Cellular bottom fitted all fore and aft for water ballast. The greater portion of the plates are in 24ft. lengths, making the structure of the ship very strong. Four steam winches, donkey boiler, patent steam steering gear amidships, screw gear aft, direct steam patent windlass, stockless anchors hauling into hawse pipes, and other modern appliances are fitted for the handy working of the vessel. The saloon and cabin, providing accommodation for the captain, &c., are handsomely finished in polished hardwood with painted panels. The steamer will be rigged as a two-masted fore and aft schooner, and has been constructed under the supervision of Mr. C. Potts, on behalf of the owners. She will be fitted with triple-expansion engines by Messrs. W. Allan and Co., Sunderland, of massive design, with every provision for the economical working of the vessel. On leaving the ways she was named Carham, by Miss Potts, of Sunderland.

There were launched on the 14th inst., at the yard of Messrs. Sir Raylton Dixon and Co., two steel coal barges, built to the order of the Steam Coal Company, of Rotterdam. These barges have been specially designed by Messrs. Flannery and Tritton, of Liverpool and London, for the transit of coal at sea, the intention being to tow them by steam tugs or by collier steamers. The system of towage by steamer for long distances at sea as an economical means of cargo transit is much in use in America, and is believed to compare favourably with the cost of conveyance in the ordinary way. The barges are each 170ft. long, with a breadth of 32ft. 6in. and 13ft. 7in. depth, and the design includes forecastle and poop decks raised 3ft. above the main deck, and running fore and aft between these two decks are continuous hatch coamings to the same height, the barge being closed in with bulwarks 3ft. 6in. high. The vessel is divided by a collision bulkhead at each end, forming peak water ballast tanks, and with two further water-tight bulkheads, forming a water ballast tank amidships, the latter compartment being further divided longitudinally. Each vessel is provided with two steam winches and a donkey boiler, together with hand steering gear and windlass, and the two masts are arranged to be lowered. The rudder is so arranged that a special movable portion may be added, and the rudder so lowered below the keel line when at sea. The decks are of steel, and the centre ballast compartment continued up to the top of the hatch coaming is also covered with a steel deck, together with a short length of the hatch top at the fore end of each hold, and on these steel covered portions are fitted the masts and winches. The portion over the centre tank is provided with two water-tight hatchways for the access of cargo. Each barge has accommodation for a crew of six hands.

Messrs. J. T. Thompson and Sons, of the North Sands Shipbuilding Yard, Sunderland, launched on the 12th inst. the steel screw steamer Howick Hall, built to the order of the Globe Shipping Company, of Liverpool, of which Messrs. C. G. Dunn and Co. are the managing owners. The principal dimensions are:—Length between perpendiculars, 356ft.; breadth, extreme, 48ft. 6in.; depth moulded, 27ft. 4in. The vessel is built on the spar-deck rules to Lloyd's 100 A1 Class, under special survey, and is a fine example of a modern cargo vessel, with all the latest improvements. Water ballast is carried in a cellular double bottom, right fore and aft, and in the after peak. The whole of the officers' and engineers' accommodation is arranged in the bridge amidships, with a limited number of spare berths for the accommodation of passengers. The crew, firemen, and petty officers are berthed in the top-gallant forecastle. The vessel is rigged as a two-masted fore and aft schooner, with telescopic top-masts to suit the Manchester Ship Canal. A large house is placed at the forward end of the bridge, used as an entrance hall to the saloon, steering-room, and chart-room, the steering gear itself being placed in the aft end of the engine casing. A powerful screw gear is fitted at the after end of the vessel. A large galley, bath-rooms, and other sanitary requirements are placed in the bridge. There are four large cargo hatches, worked by five powerful steam winches, and forward is a patent steam windlass for the working of the stockless anchors. The steamer is replete with every requirement for the comfortable accommodation of the crew, and for the rapid handling of cargoes. The engines are by Messrs. Blair and Co., Stockton-on-Tees, the size of the cylinders being 25in., 42in., and 68in., with a stroke of 45in. Steam is supplied by three large cylindrical multitubular boilers, working at 160 lb. pressure. The vessel was launched by means of hydraulic power by Miss Dunn, sister of the managing owner. The vessel was named by Miss Edith Dunn, of Clare Mount, Wallasley, daughter of the managing owner.

Messrs. David J. Dunlop and Co., engineers and shipbuilders, Inch Works, Port Glasgow, launched from their yard on Saturday a handsomely modelled steel twin screw steamer, of the following dimensions, viz.:—Length between perpendiculars, 205ft.; breadth moulded, 30ft.; depth moulded, 15ft. 9in. The steamer has been built for the New Zealand Government, and is specially designed for cable laying and repairing purposes, two large circular cable tanks being fitted, one forward and one abaft of machinery space. The cable machinery and all fittings for paying out and lifting cables have been supplied by Messrs. Johnson and Phillips, Old Charlton, London. The builders are fitting two sets of triple-expansion engines to the vessel, having cylinders 15½in., 25in., and 40in. diameter, with a stroke of 30in., and two main boilers 13ft. 1in. diameter by 10ft. 6in. long; a large auxiliary boiler is also being supplied. The whole of the machinery has been designed for a working pressure of 170 lb. The outfit of the steamer includes Napier's steam capstan, windlass, and screw steering gear; Clarke, Chapman, and Co.'s steam winches; Davis and Co.'s steam steering gear, and a complete installation of electric lighting and bells by Messrs. W. and J. Robinson, of Liverpool and London. Spacious state-room accommodation, dining saloon, and apartments for navigating and cable officers is provided amidships, whilst the petty officers' rooms and dining saloon are fitted up aft under raised quarter deck; the lighthouse keeper's quarters and crew's accommodation being placed in the forward part of the steamer. The construction of the vessel has been under the direct superintendence of Mr. W. H. Preece, C.B.; Mr. W. R. Culley, having also taken an active interest in the general arrangements and the various details, his large experience in this class of work rendering his advice of great advantage. The steamer was named Tutanekai by Miss Taylor, daughter of the late Dr. John William Taylor, Port Glasgow; and amongst those present who met in the builder's private office were Mr. W. R. Culley, Professor Jamieson and Mrs. Jamieson; Mr. Braid, Postmaster, Glasgow, and Mrs. Braid; Miss Baird, Miss Wylie, Miss Dunlop, Misses Jamieson, &c.

On Thursday, May 14th, there was launched from the shipyard of Messrs. John Readhead and Sons, South Shields, a large handsomely-modelled steamer of about 5000 tons capacity, which has been built for the Prince Line of steamers, of Newcastle-on-Tyne, and is the third vessel built and engined by Messrs. Readhead for this fleet of steamers. The directors of the Prince Line have given the composition of their fleet very careful consideration, and in common with the policy adopted by most large steamship companies, during the past year have disposed of several of the old and small steamers which have become obsolete and quite unable to compete with the greatly improved and larger vessels that, during the past few years, have been put into nearly all trades, and they are now steadily replacing them with steamers of the most modern type, of greatly augmented speed, and specially designed to meet the particular requirements of the various services worked by the vessels of the line. In pursuance of this policy, the Trojan Prince has been built more particularly for the River Plate trade, and will, no doubt, greatly enhance the reputation of the service. She is a somewhat similar vessel to the well-known Tartar Prince, which steamer at present holds the record passage to Argentina of 21 days 1 hour, and has earned for herself a very high reputation among passengers for her great steadiness at sea. The Trojan Prince is somewhat longer, has finer lines, and more powerful machinery, and is expected to attain a speed of thirteen knots fully laden, and make the passage from this country to Argentina —calling at Madeira and Teneriffe with passengers—under twenty days. Very superior passenger accommodation is provided under the bridge deck, with a large airy saloon and music room above, and there is a comfortable smoking saloon on the after part of the bridge deck. Particular attention has also been paid to the ventilation of the saloon and state-rooms, and electric fans have been fitted. The ship will be lighted throughout by electricity. The vessel is built to the highest class of Lloyd's Register, and has been specially strongly constructed. The 'tween decks are very high and available for emigrants, and she has also a large poop suitable for second-class passengers. Special attention has also been paid to the machinery and gear for the expeditious handling of mixed cargoes and heavy weights, and all the deck and other fittings are of the most recent and improved type. The Trojan Prince is expected to leave London in July for Argentina, landing passengers at Madeira and Teneriffe on her way down. She will be under the command of Captain John Hesketh, late of the s.s. Tartar Prince. The propelling machinery has been built under the inspection of Mr. John Trail, and the ship has been constructed under the supervision of Mr. M. C. James. As the vessel left the ways she was named by Miss Scott, daughter of Mr. C. H. Scott, of West Bank, Heaton Mersey, Manchester, chairman of the Prince Line.

THE PATENT JOURNAL.

Application for Letters Patent.

***** When inventions have been "comunicated" the name and address of the communicating party are printed in italics.**

7th May, 1896.

9667. Lamps, W. Fox, Lancashire.
9668. Electric Arc Lamps and Projectors, W. Fox, Lancashire.
9669. Automatic Bread-cutting Machine, J. G. Pike, Norwich.
9670. Bookmark, E. H. Shorey.—(*W. H. Shorey, West Indies.*)
9671. Combined Hollow Brased Forks, A. Bayliss, Birmingham.
9672. Construction of Door Handles, H. S. Stewart, London.
9673. Bed Hammock for Army Tent, F. E. Wood, London.
9674. Obtaining a Level Surface, W. C. Hart, London.
9675. Pneumatic Tires, J. R. Hunt, Sheffield.
9676. Treatment of Brewing Materials, J. A. Fawcett, Doncaster.
9677. Self-propelled Carriages, J. Roots, London.
9678. Sight-protecting Curlers and Wavers, W. H. Platt and E. J. Richards, London.
9679. Feed Heater, Hot Well, &c., Baron Barreto, Brandon.
9680. Dress Suspender, W. J. Fox, Manchester.
9681. Street Lighting by Glow Lamps, H. L. P. Boot, Tunbridge Wells.
96 2. Spinning and Twisting Machinery, J. M. Hetherington, Manchester.
9683. Child's Chair, Swing, and Stool, J. Mitchell, Aston.
9684. Clothes' Props, H. and E. Whittaker, Manchester.
9685. Gas and Steam Engine, E. Hoyle, Todmorden.
9686. Tennis Ball Tire, S. F. Keating, Brighton.
9687. Bicycles, F. Wynne, London.
9688. Velocipede Steadying Device, R. J. Symonds, Liverpool
9689. Making Pressed Articles, R. Bradshaw, Liverpool.
9690. Fire-escapes, I. Knapke and A. C. Robnett, London.
9691. Saw Filing Machines, J. L. McDougall, London.
9692. Ramming Vessels, T. F. Drew, London.
9693. Home Training with Velocipedes, G. Beard, Manchester.
9694. Wheels, J. Burtinshaw, W. Moores, and M. Conlan, Manchester.
9695. Cycle Gear Cases, V. Dugmore, Birmingham.
9696. Cycles, E. M. Carter, London.
9697. Driving Gear, S. G. Mason, R. F. Goyne, and J. Tonry, London.
9698. Puzzle Box, T. H. Saunders and J. H. Brindley, Birmingham.
9699. Decanting Apparatus, C. W. Rands-Allen and W. Boby, London.
9700. Bicycles, Tricycles, &c., W. Madigan, Manchester.
9701. Bicycles and Velocipedes, F. Alexander, Jersey.
9702. Blotters, O. R. Fischer, Germany.
9703. Combined Furniture, W. O. Weddle, Newcastle-on-Tyne.
9704. Feeding Appliances for Animals, P. J. Skill, Nottingham.
9705. Ladies' Dress Pockets, J. Wollman, Rotherham.
9706. Brake Apparatus for Cycles, W. J. Simmons, Bristol.
9707. Platen Printing Machines, C. Butterfield, Nottingham.
9708. Tires for Wheels, W. H. W. and E. P. Furrell, London.
9709. Removing Solids from Vacuum Pans, R. H. F. Finlay, Belfast.
9710. Brakes, &c., D. Tindall and J. Dunbar, Glasgow.
9711. Perpetual Calendars, A. Glendinning, Glasgow.
9712. Stays for Boilers, J. A. McKie and P. M. Baxter, Glasgow.
9713. Signal Indicator for Locomotives, D. Foulis, Glasgow.
9714. Driving Belt Coupling, R. Breckenridge, Glasgow.
9715. Valves, J. Y. Johnson.—(*Redway Manufacturing Co., United States.*)
9716. Waste or Slop Water-closets, T. Dawber, London.
9717. Manufacture of Toy Balloons, J. Harris, Manchester.
9718. Folding Tables, Stands, &c., J. Robertson, Glasgow.
9719. Patent Cyclist Toilet Compactum, J. Cook, London.
9720. Burglar Alarm, J. A. Kelman and H. Yuill, London.
9721. Means for Projecting Boxes, J. M. Banks, London.
9722. Wheel Tires for Bicycles, &c., F. Duffett, Acton.
9723. Corner Mounts for Fenders, G. E. Lancelott, Birmingham.
9724. Pneumatic Tires, E. G. Edmands and R. Edlin, Birmingham.
9725. Rims for Bicycles and Carriages, J. C. Cole, London.
9726. Bill Head Hooks, F. G. Fender and W. E. Coleman, London.
9727. Corset, G. P. Festa, London.
9728. Corset, G. P. Festa, London.
9729. Raising and Lowering Boats, J. Griffin, London.
9730. Tire, S. M. Frankenstein, London.
9731. Coin-freed Game, E. G. Matthewson, London.
9732. Explosion Motor, C. A. de Dion and G. Bouton, London.
9733. Brake Mechanism, C. A. de Dion and G. Bouton, London.
9734. Steering Carriages, C. A. de Dion and G. Bouton, London.
9735. Cycle Handles, G. S. Wallis, London.
9736. Spoons, T. Edge, London.
9737. Pneumatic Tires for Velocipedes, E. M. Payne, London.
9738. Sky Signs, W. C. Barns, London.
9739. Hair Retainer, E. Coombs, Southampton.
9740. Preventing Escape of Acids, H. Gronwald, London.
9741. Thermometric Alarm Apparatus, J. J. Hicks London.
9742. Pianoforte Action, W. Yarrow and L. Courtice, London.
9743. Switching Device, W. P. Thompson.—(*J. Csasznek and M. Kollmann, Austria.*)
9744. Bicycle Lantern, C. M. Bump, London.
9745. Pickers for Looms, J. M. Rose, Manchester.
9746. Packing Lobsters, W. M. Simpson.—(*F. Roberts, Canada.*)
9747. Locking Bicycles and Tricycles, J. C. Grant, London.
9748. Warp Tension, J. Poyser and G. W. Barrows, London.
9749. Treating Refractory Ores, F. Ellershausen, London.
9750. Handle Bars, J. Galt, A. P. Rankin, P. R. Wright, and M. E. Wright, London.
9751. Boat Propelling Apparatus, A. C. C. Asenar, London.
9752. Gum Bottles, G. Musgrove, London.
9753. Grates, H. J. Bickley, jun., London.
9754. Buffers for Railway Locomotives, J. Cowen, London.
9755. Device for Cutting Oranges, H. T. Mylan, London.
9756. Gearing for Cycles, T. A. G. Frost, London.
9757. Inflatable or Pneumatic Tires, H. S. Maxim, London.
9758. Floorcloths or Carpets, &c., F. Fanta, London.
9759. Motor Vehicles, A. J. Boult.—(*La Société Justin Landry and G. Beyroux, France.*)
9760. Transparent Enamels, W. H. Forester and G. Bland, London.
9761. Fastenings for Coffins, A. Smith, London.
9762. Engine Governors, A. S. F. Robinson, London.
9763. Raw Hide and other Belting, S. Schreiber, London.
9764. Letter Boxes, F. Freegard, London.
9765. Indicating or Signalling Apparatus, A. Friis, London.
9766. Bicycles and Tricycles, &c., C. T. Mitchell, London.
9767. Dyeing Fabrics, J. Reixach and F. Bamford, London.
9768. Double Shuttle Looms and Weaves, J. Reixach, London.
9769. Tire Rim for Cycles, G. Fellowes, London.
9770. Gas Engines, J. A. Hockett, Missouri, U.S.A.
9771. Pneumatic Brakes for Cycles, J. J. Eckert, Strood.

8th May, 1896.

9772. Separating Metals from Ores, &c., J. Lyle, London.
9773. Machinery for Separating Purposes, A. S. F. Robinson, London.
9774. Wheels of Cycles and Vehicles, S. Greenwood, Liverpool.
9775. Filter Funnel, E. E. Heyliss and C. G. Oppermann, Henley-on-Thames.
9776. Ventilator for Carriages, C. E. P. Gabriel, Birmingham.
9777. Boot and Shoe Fastener, J. P. Furlong, Youghal.
9778. Carding Engines, W. Hopkinson and R. Tyack, Accrington.
9779. Construction of Cue Cases, W. J. Peall, London.
9780. Rulers, R. W. Hodgson, Newcastle-on-Tyne.
9781. Wall Bracket for Photographs, W. J. Robinson, Bristol.
9782. Strainers for Baking Pans, &c., L. W. Lee, Bilston.
9783. Beverage for Invalids, J. C. Harvey, Wolverhampton.
9784. Pumping Water, J. Hughes and C. Lancaster, Liverpool.
9785. Machines for Washing Clothes, A. Barrett, Keighley.
9786. Cigars, A. E. Smith, Huddersfield.
9787. Moulding Boot Stiffeners, W. H. Dorman, Stafford.
9788. Connections, &c., for Pipes, H. P. Lavender, Walsall.
9789. Superphosphates, F. M. Mooney and A. Dickson, Dublin.
9790. Stop Indicator for Road Cars, E. Causon, Bristol.
9791. Preventing Puncture in Tires, E. T. Morland-Johnson, Blaenau Festiniog.
9792. Dish for Photographic Purposes, W. S. Wain, Ripley.
9793. Protector for Chest and Lungs, W. Brown, Swansea.
9794. Brushes, &c., W. L. Byers, Sunderland.
9795. Operating Cash Tills, S. Mason and W. Snelgrove, Birmingham.
9796. Tobacco Pipes, F. Page, London.
9797. Bottles, H. B. Lowe and P. Harris and Co., Birmingham.
9798. Game, H. O. and J. O. Roberts, Gloucester.
9799. Photographic Printing Frames, E. Marlow, jun., and T. Marlow, Birmingham.
9800. Cycles, J. Darling, Glasgow.
9801. Locks for Railway Carriage Doors, D. Maxwell, Dundee.
9802. Spectacles, A. Marshall, Glasgow.
9803. Filtering Presses, J. Williamson, Glasgow.
9804. Wheel Tires, W. H. Luther and J. Cockburn, Glasgow.
9805. Scrubbing Brushes, H. Rowlands, Liverpool.
9806. Starting, &c., Electro-motors, H. Pieper, fils, London.
9807. Sleeve Links and Solitaires, J. Cheshire, Birmingham.
9808. Adapting Books for Postage, F. Richmond, London.
9809. Animal Traps, E. C. Waldurf and F. T. Reynolds, London.
9810. Guard, &c., for Carving Forks, J. Forbes, London.
9811. Folding Cots, T. Bass and C. M. Römpler, London.
9812. Cycle and other Oil Lamps, H. Salsbury, London.
9813. Velocipedes and Rolling Stock, A. Squire, London.
9814. Manufacture of Roofing Tiles, C. Wicke, London.
9815. Safety Revolving Window Frame, W. Tomlin, London.
9816. Coin-operated Gas Meter, W. Britain, jun., London.
9817. Electric Lamps, E. Bach, H. S. Lewis, and A. B. Saunders, London.
9818. Tools for Making Boots, &c., C. W. Harvey, London.
9819. Puzzles, H. Marles, Brighton.
9820. Coupling-boxes for Electric Circuits, M. Binswanger and F. G. Bell, London.
9821. Saddle for Velocipedes, H. P. de Lastelle, London.
9822. Anti-friction Ball Guide, C. H. Worley, London.
9823. Pneumatic Tires and Rims therefor, P. Mercier, London.
9824. Holder for Legs of Mutton, A. Mention, London.
9825. Manuacture of Needles, A. Schoeneweiss, London.
9826. Cork-drawing Machines, A. Whitfield, London.
9827. Velocipedes, W. H. Williams, London.
9828. Polishing Apparatus, N. W. Russ, London.
9829. Producing Designs upon Paper, G. R. Hildyard, London.
9830. Preventing Skirts from Sagging, C. G. Mackay, London.
9831. Tires for Wheels of Bicycles, J. C. F. Johnson, London.
9832. Exchange Telephone Systems, J. E. Kingsbury. —(*The Western Electric Company, United States.*)

9833. Reproducing Pictures, &c., J. H. Player, London.
9834. Window Sashes for Carriages, E. Cunningham, Liverpool.
9835. Measuring, &c., Liquids, T. Saccaentz, Manchester.
9836. Boots and Shoes, W. Ward, Birmingham.
9837. Velocipedes and Road Vehicles, H. D. Dance, London.
9838. Compositions for Building Purposes, J. Wilkinson, London.
9839. Carrying-off Liquid Deposits, E. de Brabander, London.
9840. Protecting Travellers' Boxes, J. M. Banks, London.
9841. Incandescent Gas Lighter, C. Weston, London.
9842. Preparing Milk Sugar from Milk, H. Edwards, jun., London.
9843. Electric Current Meters, &c., R. P. Wilson, London.
9844. Feed-water Purifying Apparatus, J. Bruun, London.
9845. Hat Grip, J. N. Spence, London.
9846. Bedsteads, J. H. Morley, London.
9847. Sinking and Lining Mining Shafts, C. Walker, London.
9848. Embroidering Machines, E. and R. Cornely, London.
9849. Looms for Weaving, J. A. Bannister, London.
9850. Spring Clutch Mechanism, A. Brancher, London.
9851. Swath-turners, E. C. Blackstone, London.
9852. India-rubber Printing Stamps, F. R. Houten, London.
9853. Electric Belts and Appliances, E. S. Col icott, London.
9854. Nosebag Support, D. Black, London.
9855. Boots and Shoes, G. T. Mackley, London.
9856. Bottle Capsules and Labels, E. M. Llewellyn, London.
9857. Taps, H. Hatton, T. W. Nayler, and G. Nayler, London.
9858. Ejector Mechanism of Linotype Machines, The Linotype Co., Ld.—(*The National Typographic Company, United States.*)
9859. Distributing Mechanism of Linotype Machines, The Linotype Co., Ld.—(*The National Typographic Company, United States.*)
9860. Drawing Implement, G. Grund, London.
9861. Burners for Acetylene Gas, E. Hütter, London.
9862. Liquefying Acetylene Gases, E. Hütter, London.
9863. Card Cases, A. J. Needham and W. C. Needham, London.

9th May, 1896.

9364. Wristband Cuff Attachment, M. A. Alger, London.
9865. Clip for Trousers, &c., E. de V. du Boulay, Isle of Wight.
9866. Saddles for Treadle Machines, A. W. Murray, Dublin.
9867. Earthenware Pipe Joints, &c., R. Ewing, London.
9868. Saddles for Bicycles, &c., W. G. Manwaring, Banbury.
9869. Machines Driven by a Crank, R. Ewing, London.
9870. Screw, C. Leigh, London.
9871. Pickers for Underpick Looms, J. Curtis, Manchester.
9872. Rollers for Dyeing Apparatus, H. D. Halstead, Manchester.
9873. Golf Clubs, C. D. McLachlan and P. S. Grant, Glasgow.
9874. Thermometers, G. Bennett, London.
9875. Game of Cards, G. Chalmers, London.
9876. Apparatus for Balling Warps, J. Rhodes, Bradford.
9877. Stopping Shrinkage of Fabrics, T. Illingworth, Bradford.
9878. Music Stools and the like, A. Plant, Glasgow.
9879. Railway Brakes, J. W. White, Liverpool.
9880. Tennis Balls, W. P. Wethered, Liverpool.
9881. Dregs Guard for Teacups, &c., H. Britten, Sheffield.
9882. Closing Water-tight Doors, J. A. Crawford and T. A. Crawford, Newcastle-on-Tyne.
9883. Check Registers, A. Cotgreave and W. Morgan, Birmingham.
9884. Cycle Prop, J. Reynolds and J. Reynolds, jun., Nottingham.
9885. Gearing of Bicycles, J. Plummer, Midlothian.
9886. Cases for Holding Cutlery, &c., J. C. Wain, Sheffield.
9887. Raising Nap on Fabrics, J. Tomlinson, Manchester
9888. Menstrual Pad, F. W. Cates and G. Graham, London.
9889. Brakes for Railway Trucks, T. W. Mayos, Trewaugh.
9890. Kinoscopic Apparatus, W. Hunt and J. Trotter, Bothwell.
9891. Leather Skiving Machine, E. E. Bartlett, United States.
9892. Adjustment of Seats and Saddles, E. J. Byrne, Dublin.
9893. Carrying Bag, W. M. Storrar and W. Maconachie, Dundee.
9894. Fire-grates and Stoves, S. H. Crocker, London.
9895. Cup Stands, Mansell, Hunt, Catty, and Co., Ld., and F. H. Taylor, London.
9896. Registering Safety Till and Box, M. Bliss, London.
9897. Basket for Market Produce, W. C. Mullett, London.
9898. Cycle Rest or Supports, H. Howland, London.
9899. Wheels, F. Klingelhöfer, London.
9900. Fixing Collars, J. W. Vose and J. Parkinson, London.
9901. Glass Etching Plates for Copying, T. Löhler, Berlin.
9902. Crank Driving Gear, A. E. G. Birkbeck, London.
9903. Locks, W. Ferdinand and E. Lyon, London.
9904. Saddles for Cycles, M. de Laski, London.
9905. Binders or Files for Music, G. W. Owen, London.
9906. Moistening Device, The Rapid Damper Company, Ld., and J. Parker, London.
9907. Chimneys, M. G. J. Bate and F. W. Collins, London.
9908. Compressed Bakers' Yeast, M. P. Hatschek, London.
9909. Hair Curlers, A. Rowe, London.
9910. Secondary Batteries, A. Schanschieff, London.
9911. Stands to Exhibit Cut Flowers, W. B. Press, Leytonstone.
9912. Black Azo Dyestuffs, E. R. von Portheim, London.
9913. Tires and Wheels for Vehicles, H. Hicks, London.
9914. Stylographic Paper, L. Capazza, London.
9915. Showcards, Tablets, &c., J. R. Phelps, London.
9916. Connecting the Pedals of Cycles, A. E. Payne, Barnes.
9917. Cycle Stands, W. P. Thompson.—(*J. B. Fondu, Belgium.*)
9918. Fastener for Boots and Shoes, W. Kretschmann, Liverpool.
9919. Electrical Exhausted Tubes, W. Friese-Greene, London.
9920. Supplying Currents of Air, G. R. Hildyard, London.
9921. Carding Engines, J. Y. Johnson.—(*Maschinenfabrik O. Schimmel and Co., Germany.*)
9922. Making, Lighting and Heating Gas, J. Sibley, London.
9923. Increasing Stability of Beer, H. Gronwald, London.
9924. Cartridge Clips, H. H. Lake.—(*The Lee Arms Company, United States.*)
9925. Magazine Fire-arms, H. H. Lake.—(*The Lee Arms Company, United States.*)
9926. Match-boxes, J. H. Iredale, London.
9927. Uniting Broken Shafts, A. C. Sheppard, London.
9928. Furnaces for Heating and Drying, L. Richard, London.
9929. Self-returning Bell Indicator, R. W. Lane, London.
9930. Regulating Motion for Twiners, J. Battersby, Bolton.
9931. Pedals, H. Gstirner, London.
9932. Bicycles, G. E. Wade, London.
9933. Sleeve Links or Fastenings, J. Gordon, Birmingham.
9934. Roller Blind Ends or Fittings, F. W. Nicholls, Birmingham.

11th May, 1896.

9935. Developing Photographic Plates, &c., J. G. Williams, Manchester.
9936. Tubular Knitted Fabrics, O. Tabberer, A. Lorrimer, G. O. Tabberer, M. Lorrimer, and F. S. Shipp, Leicester.
9937. Revolving Link Ladder, C. W. G. Aldridge, Feltham.
9938. Mustard Plasters, J. Millard, London.
9939. Cycles, C. Merington, London.
9940. Four-way Valves for Furnaces, C. Wood and A. C. Caddick, Sheffield.
9941. Woollen Bleaching, T. Parry-Jones, Montgomeryshire.
9942. Mechanically-operated Vehicles, J. Southall, Worcester.
9943. Steel Shape for Soft Felt Hats, W. J. Clarke, Great Yarmouth.
9944. Vertical Retorts, A. C. Thomson, Cobbinshaw, near Edinburgh.
9945. Ball Valve, R. and G. Harding, London.
9946. Pie-making Machinery, J. S. Smith, Bradford.
9947. Covers for Tobacco Pipes, A. A. Percy, London.
9948. Feeding Water into Steam Boilers, W. Burns, Glasgow.
9949. Staff-notation Music, J. Findlay, Glasgow.
9950. Means for Disinfecting Purposes, R. S. Brownlow, Manchester.
9951. Toy or Race Game, P. Pownall, Manchester.
9952. Railway Carriage Windows, W. Wright, Manchester.
9953. Brakes for Cycles, T. Crowther, Bradford.
9954. Tire and Rim for Cycles, &c., R. Willington, London.
9955. "Swathing" for Mowing Machines, G. Farris, Salisbury.
9956. Automatic Mudgards for Bicycles, E. and E. Hodgson, Manchester.
9957. Metallic Packings, W. P. Thompson.—(*T. Lister, South Africa.*)
9958. Multiplying Power of Steam, &c., J. Davies, Pembrokeshire.
9959. Electrical Arc Lamps, W. H. Lauder, Dublin.
9960. Electric Bell Communication, F. Helman and J. Carroll, Liverpool.
9961. Camp Bedstead and Bed, B. Burleigh, London.
9962. Portable Shower Bath Ring, W. H. Slade, Bristol.
9963. Game and Pieces for Playing Same, J. E. and H. J. Griffiths, London.
9964. Electric Cables, G. H. Nisbett, Liverpool.
9965. Scavenger Brushes, S. Mann, London.
9966. Loom Shuttles, T. Walker, London.
9967. Finger Plates for Doors, W. H. Richardson-Jones, London.
9968. Match-boxes, &c., E. H. Levi, London.
9969. Machine for Cleaning Boots, A. R. Bowcher, London.
9970. Adjustable Picture Hoist and Hanger, C. Hamlyn, London.
9971. Pneumatic Tire, T. M. Down, London.
9972. Wheels for Cycles, F. W. Jones, Kingston-on-Thames.
9973. Screw-winged Flying Machines, H. Middleton, Slough.
9974. Electrical Switches, M. Binswanger and F. G. Bell, London.
9975. Conduits for Electrical Conductors, F. Bathurst, London.
9976. Hand Telephones, M. Binswanger and F. G. Bell, London.
9977. Covering Pianoforte Hammer Heads, A. J. Harrison, Wealdstone.
9978. Communicating Motion, C. Frost-Foster and H. W. Seager, London.
9979. Ball Tire, W. Meadows, London.
9980. Self-adjusting Packing Ring, J. A. Magill, London.
9981. Lamps, H. Lane, London.
9982. Internal Combustion Engines, H. Lane, London.
9983. Pen for Birds, W. E. B. Macaulay, London.
9984. Winding Yarn, A. B. Morse, London.
9985. Elastic Tires, H. Smith, Harrow-on-the-Hill.
9986. Cigar Holders, E. Savor, London.
9987. Court Plaster, H. H. Lake.—(*Boston Curative Company, United States.*)
9988. Automatic Liquid Level Indicator, F. A. Morse, London.
9989. Cycle Saddles, A. Baxter, London.
9990. Driving Gear for Cycles, J. P. C. Rigby, London.
9991. Cycle Handles, F. W. Gunton, London.
9992. Electric Traction, H. J. Allen, London.
9993. Hoisting Goods, A. G. Hadcock and C. W. Hutchinson, London.
9994. Automatic Clutches, A. W. Peust and E. Tewis, Liverpool.
9995. Automatic Punkahs and Fans, W. Turvey, London.
9996. Tires for Cycles, G. V. de Luca and S. Hill, London.
9997. Traps for Condensed Steam, G. Fletcher.—(*E. Y. Connell, West Indies.*)
9998. Producing Motive Power, E. B. Badcock, jun., London.
9999. Bicycles, C. F. Pfeiffer, London.
10,000. Fresco Painting, O. Matthiesen, London.
10,001. Wheels, W. Aves, London.
10,002. Transmitting Power, Count A. de Dion and G. Bouton, London.
10,003. Cinnamic Aldehyde, J. Y. Johnson.—(*C. F. Boehringer and Soehne, Germany.*)
10,004. Making Derivatives of Xanthine, E. Fischer, London.
10,005. Preparing Alkylated Uric Acids, E. Fischer, London.
10,006. Receiving Photographic Images, A. F. Parnaland, London.
10,007. Wheels, W. A. Konemann, London.
10,008. Securing Objects to Cycles, O. Imray.—(*C. Schilbers, Austria.*)
10,009. Machine for Shaping Metals, C. Nube, London.
10,010. Rasps, W. Shaw, H. A. Parkin, and B. C. McRae, London.
10,011. Car Coupler, W. R. Fine, London.
10,012. Dress Shields, M. F. P. Miles, London.
10,013. Air Regulating Device, W. H. A. Sieverts, London.
10,014. Ball Bearings, N. Rousselle, London.
10,015. Writing Telegraphs, R. J. Crowley and A. B. Hutchings, London.
10,016. Eyes for Fastening Dresses, E. N. W. Madigan, London.
10,017. Arc Lamps, W. J. Davy, London.
10,018. Constructing Motive Power Apparatus, H. Lane, London.
10,019. Stays for Steam Boilers, R. T. Preston and J. Holden, London.
10,020. Driving Gear for Bicycles, W. Woodman, London.
10,021. Speaking Tubes or Voice Pipes, H. A. Cutmore, London.

12th May, 1896.

10,022. Ladies' Pillion Bicycle Saddle, R. Harper, High Wycombe.
10,023. Nursery Chairs, O. Townsend, London.

10,032. Cases for Holding Papers, S. Learoyd, Huddersfield.
10,033. Reproduction of Moving Objects, S. D. Williams, Newport, Mon.
10,034. Valve, N. Dakin, Leeds.
10,035. The Cleanser Washing Machine, E. Scott, Bristol.
10,036. Brake Attachments for Cycles, M. Lintine, Birmingham.
10,037. Gully Traps, J. Richards, Bristol.
10,038. Fireproof Doors, T. C. Fawcett, Halifax.
10,039. Pocket-knives and Corkscrews, C. H. Müller, Manchester.
10,040. Cycle Saddles, J. B. Brooks, Birmingham.
10,041. Match Strikers for Boxes, H. Allday, Birmingham.
10,042. Castor for Chairs, W. U. Coates, Falfield.
10,043. Delivering Liquid Matter, E. C. Matson, Dublin.
10,044. Steam Engines, C. Devine, Glasgow.
10,045. Moistening Gummed Labels, W. Weir, Milngavie.
10,046. Shuttles for Weaving, J. Wilson and J. Lumb, Leeds.
10,047. Electrical Transportation, P. K. Stern, London.
10,048. An Improved Puzzle, W. Johnson, Liverpool.
10,049. Pneumatic Inflating, H. F. Easton, Middlesex.
10,050. Automatic Brake for Bassinettes, J. Taylor, Bacup.
10,051. Spoons, A. Nicol, Middlesex.
10,052. Elastic Tires for Velocipedes, E. P. Allam, London.
10,053. Pressure Generator, J. Anderson, C. Dickie, and R. Dickie, Glasgow.
10,054. Golfette, A. G. Porteous, Stirling.
10,055. Multitubular Tyre, G. Ramsay, London.
10,056. Hygienic Boot, F. H. Nicolai, Berlin.
10,057. Cash Registers, J. R. Ward, London.
10,058. Change-giving Apparatus, J. R. Ward, London.
10,059. Cigar and Cigarette Holders, T. Dawber, London.
10,060. Stopping Machinery, G. Edgar and Tasker, Sons, and Co., Sheffield.
10,061. Charging Blast Furnaces, T. Lewis, Birmingham.
10,062. Power Crank for Cycles, H. L. Todd and W. Wright, London.
10,063. Railway Car or Vehicle, A. Bierstadt, London.
10,064. Portable Cycle Rest, N. Pogose, London.
10,065. Shoemakers' Tools, I. Golfarelli, P. Buob, and T. Banchi, London.
10,066. Duplicating Graphophone Records, J. Y. Johnson.—(*The American Graphophone Company, United States.*)
10,067. Disinfecting with Chlorine, R. N. Lennox, London.
10,068. Making Tires for Vehicle Wheels, J. C. Cole, London.
10,069. Electrically Controlling Guns, M. Pfatischer, London.
10,070. Bicycle and Carriage Frames, W. H. Price, London.
10,071. The Chepstow Aneroid, H. J. R. Lowe, London.
10,072. Photo Negatives, A. Hill and the Cresco Fylma Company, London.
10,073. Files for Letters and other Papers, I. N. Adrian, London.
10,074. Detachable Tires for Wheels, M. Bliss, London.
10,075. Automatic Fog Signal Apparatus, C. H. Fox, London.
10,076. Metal Canisters or Packing Tins, J. D. Falk, London.
10,077. Galvanised Hot-water Tanks, W. Skaiff, London.
10,078. Locomotive Tires, H. H. Lake.—(*H. A. Harvey, United States.*)
10,079. Locomotive Tires, H. H. Lake.—(*H. A. Harvey, United States.*)
10,080. Hat Shaping Flanges, F. L. F. Butterworth, London.
10,081. Speed Countershafts, H. H. Lake.—(*M. White, United States.*)
10,082. Kettles, J. Beale, London.
10,083. Repairing Tires, A. R. Mallard, E. C. Toller, and H. A. Slade, London.
10,084. Web Printing, &c., Machines, R. C. Annand, London.
10,085. Pipe Coupling, A. W. F. Bennik, London.
10,086. Non-refillable Bottles, F. Coirin, London.
10,087. Paper Cutting Machines, P. M. Justice.—(*The Seybold Machine Company, United States.*)
10,088. Water-closet Valves, J. W. Bragger, London.
10,089. Manufacture of Wheel Tires, H. J. Doughty, London.
10,090. Brakes or Supports for Cycles, H. A. Lazarus, London.
10,091. Flue Cleaners, R. Haddan.—(*M. G. Cook, United States.*)
10,092. Transmitting Motive Power, W. Kneen, Manchester.
10,093. Driving Gear for Velocipedes, J. H. Keeble, London.
10,094. Garters, B. Dreyfus, London.
10,095. Electric Batteries, P. Schmidt, London.
10,096. Arc Electric Lamps, A. O. Mackin, London.
10,097. Treatment of Gold Bearing Ores, J. Jones, London.
10,098. Gauge Glasses for Steam Boilers, J. E. L. Ogden, London.
10,099. Support for Cans and Cases, T. W. Hickson, London.
10,100. Knitting Machines, G. C. Marks.—(*E. Spear, F. L. Middleton, W. E. Richards, and W. W. White, United States.*)
10,101. Valves for Rock Drills, A. W. and Z. W. Daw, London.
10,102. Regulating Gas, R. T. and J. G. Glover, London.
10,103. Steering Handles for Cycles, F. W. Oliver, London.
10,104. Material for Belting, &c., F. W. Oliver, London.
10,105. Making Water-proof Fabrics, F. W. Oliver, London.
10,106. Step-by-step Printing Telegraphs, W. S Steljes, London.
10,107. Machines for Driving Hoops, A. Lieber, London.
10,108. Speed Gearing for Cycles, J. E. Preston, London.
10,109. Improved Artificial Manure, O. G. Blunden, London.
10,110. Stretcher for Boots, &c., C. W. Braithwaite, London.
10,111. Protectite Sole for Boots, &c., W. Jeggle, London.
10,112. Oil Lamps, W. F. Broomhead, Liverpool.
10,113. Cycle Tire Covers, J. Griffiths and J. Fitzsimins, Liverpool.
10,114. Pneumatic Tires, F. S. Bellhouse, G. R. Bellhouse, and F. R. Clarke, Birmingham.
10,115. Driving Gear for Cycles, T. E. Nightingale, Liverpool.
10,116. Pneumatic Tires for Velocipedes, A. Willis, London.
10,117. Cowls for Ventilating Shafts, &c., L. Pitsch, Liverpool.
10,118. Obtaining Photographic Maps, A. V. Newton.—(*A. Nobel, France.*)
10,119. Electrical Thief Alarm, J. Pearson and W. Gooding, London.
10,120. Dust Bags, D. Hunt, London.
10,121. Soldering Lamps and Soldering Irons, J. Fouilloud, London.
10,122. Sinking Wells, A. Lengauer, London.
10,123. Lever Carving Fork Attachment, J. S. Lockeyear, London.
10,124. Distribution of Electric Currents, J. Devonshire.—(*C. P. Steinmetz, United States.*)
10,125. Pneumatic Tubes, J. L. Hancock, London.
10,126. Gas Generators, W. Jordan.—(*The Morley Acetylene Gas Company, United States.*)
10,127. Electric Tram Trolleys, A. H. Leigh.—(*H. R Keithley, United States.*)
10,128. Hydrocarbon Motor Engines, J. Y. Johnson.—(*A. and C. Janet, France.*)
10,129. Brakes for Velocipedes, H. R. Newburgh-Stewart, London.
10,130. Motor Wheel, J. P. E. Proud, London.
10,131. Manufacture of Bread, &c., W. W. Macadam, London.
10,132. Straw Caps, H. L. Dixon and C. Wright, London.
10,133. Apparatus for Playing a New Game, I. Sulzbacher, London.
10,134. System for Collection of Electricity, W. J. Brewer, London.
10,135. Typewriters, J. C. Fell.—(*The Densmore Typewriter Co., United States.*)

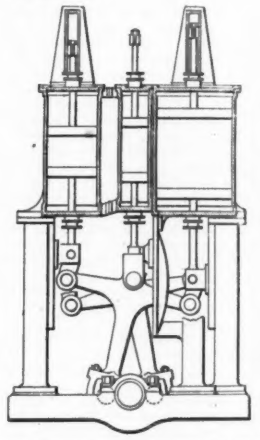
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

554,966. Steam Engine, *E. E. Wigzell, London, England.—Filed July 31st*, 1895.

Claim.—(1) A triple-expansion steam engine having two pistons working in opposite directions in each of its three cylinders, a three-throw crank shaft, a central triangular connection interposed between the rods of one set of pistons, and the middle crank of said crank shaft, and like triangular connections, together with connecting rods and crossheads, connecting the rods of the other set of pistons with the outer cranks of said crank shaft, substantially as hereinbefore specified. (2) In a steam engine, the combination with a three-throw crank shaft and cylinders placed in a line at right angles to said crank shaft, of two pistons working in opposite directions in each cylinder, a central triangular connection interposed between the rods of one set of pistons and the middle crank of said crank shaft, and like triangular connections, together with connecting rods and crossheads, connecting the rods of the other set of pistons with the outer cranks of said crankshaft, substantially as hereinbefore specified.

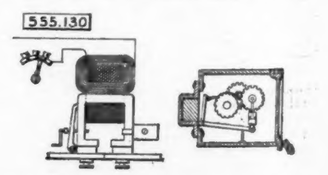
554.966



555,130. Electric Welding Indicator, *E. Thomson, Lynn, Mass.—Filed July 23rd*, 1888.

Claim.—(1) The combination with an electric welding, forging, brazing, or other electric metal working apparatus, of a register or counter, a reciprocating actuating or controlling device therefor responsive to the flow of an electric current accompanying the heating of the work, and a retarding device connected to the said reciprocating mechanism, as and for the purpose described. (2) The combination with the conductor and the register operated or controlled by the current in said conductor, of the iron bar or strap M, fastened transverse to said conductor, and an armature arranged to be attracted to said strap, as and for the purpose described.

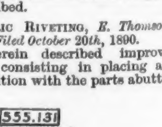
555.130



555,131. Electric Riveting, *E. Thomson, Swampscott, Mass.—Filed October 20th*, 1890.

Claim.—The herein described improvement in electric riveting, consisting in placing a two part rivet blank in position with the parts abutting within the pieces to be fastened together, passing an electric current through such abutting portions, and then subjecting the same to endwise pressure so as to weld the two parts together to complete the rivet and at the same time form a head or enlargement to give increased resistance against shearing strain.

555.131



ISLINGTON ELECTRIC LIGHT STATION.

ISLINGTON has now followed the lead of other metropolitan parishes, such as St. Pancras and St. John, Hampstead, and the Vestry of St. Mary, Islington, has undertaken the work of public supply of electricity. The parish is very large, having a rateable value of £1,771,420 and nearly 45,000 hereditaments; it covers an area of 3109 acres, and has 120 miles of streets.

Without describing the various abortive attempts made by the Vestry in former years to obtain a public supply of electricity, we may say that a committee was appointed to examine the question, and it presented a preliminary report in July, 1892, reccmmending that application should be made to the Board of Trade for a provisional order. The committee then visited a large number of electric light stations in the country, with a view of selecting the most suitable system, and submitted a report, which was laid before the Vestry in March, 1893. In the report they pointed out that, in view of the fact that the area to be supplied was a very large one, and that the mains would be of great length, they considered that the alternating system with transformers would be most suitable for private lighting and the high tension continuous current system for public lighting.

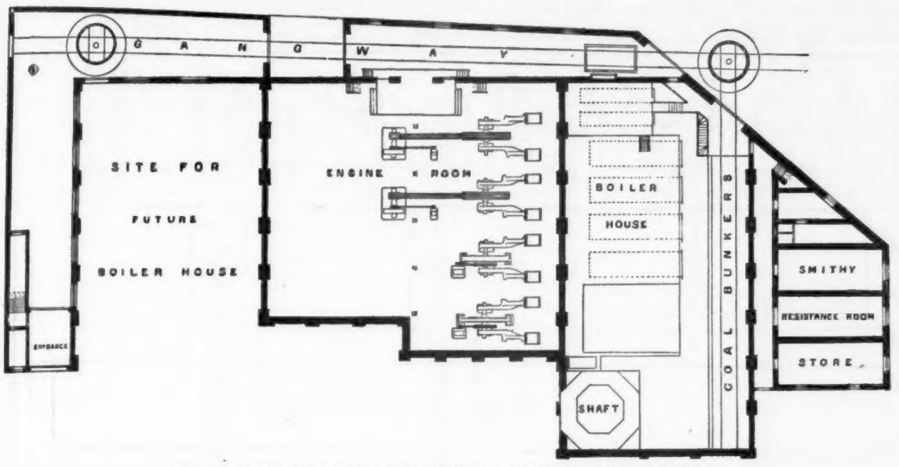


Fig. 1—GENERAL PLAN OF ISLINGTON ELECTRIC LIGHT STATION

The report was accepted, and instead of retaining a purely consulting engineer, the Vestry appointed in public competition Mr. Albert Gay, M.I.E.E., as electrical engineer, to prepare the necessary plans and specifications, to superintend the works while in progress, and to take over the whole undertaking as manager on completion. The work was taken up in October, 1893, and soon after this a site in the centre of the area was selected and bought, and Mr. A. Hessel Tiltman, F.R.I.B.A., was appointed architect to the Vestry. The work of pipe-laying began in October, 1894, and the foundation stone of the building was laid in December, 1894, by Mr. Lambert, the chairman of the Electric Lighting Committee.

In order to give some idea of the amount of public lighting which may eventually be required, we may state that on Lady-day, 1895, the number of public street lamps was 4648, and the gas supplied to them cost 2s. 3d. per 1000 cubic feet, making a total cost for the year of £13,916, exclusive of fittings. The site acquired for the generating station is about three-quarters of an acre in extent, and it is bounded on two sides by the Great Northern Railway, these having great facilities for the delivery of coals and other materials. It is freehold, and was bought by the Vestry from the Great Northern Railway Company; at the same time some adjoining cottages were bought, with a view to the possibility of future extension, and also to avoid any possibility of an injunction being obtained against them for vibration caused to the property of adjacent owners. During last year the work of construction was in full progress, and in our issue of the 6th March we gave a short account of the opening ceremony, which took place on March 4th of this year.

Fic 1ᴬ.

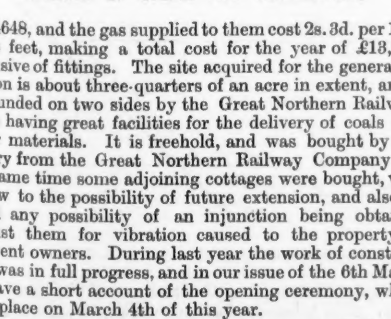

DIAGRAM OF STEAM PIPE CONNECTIONS

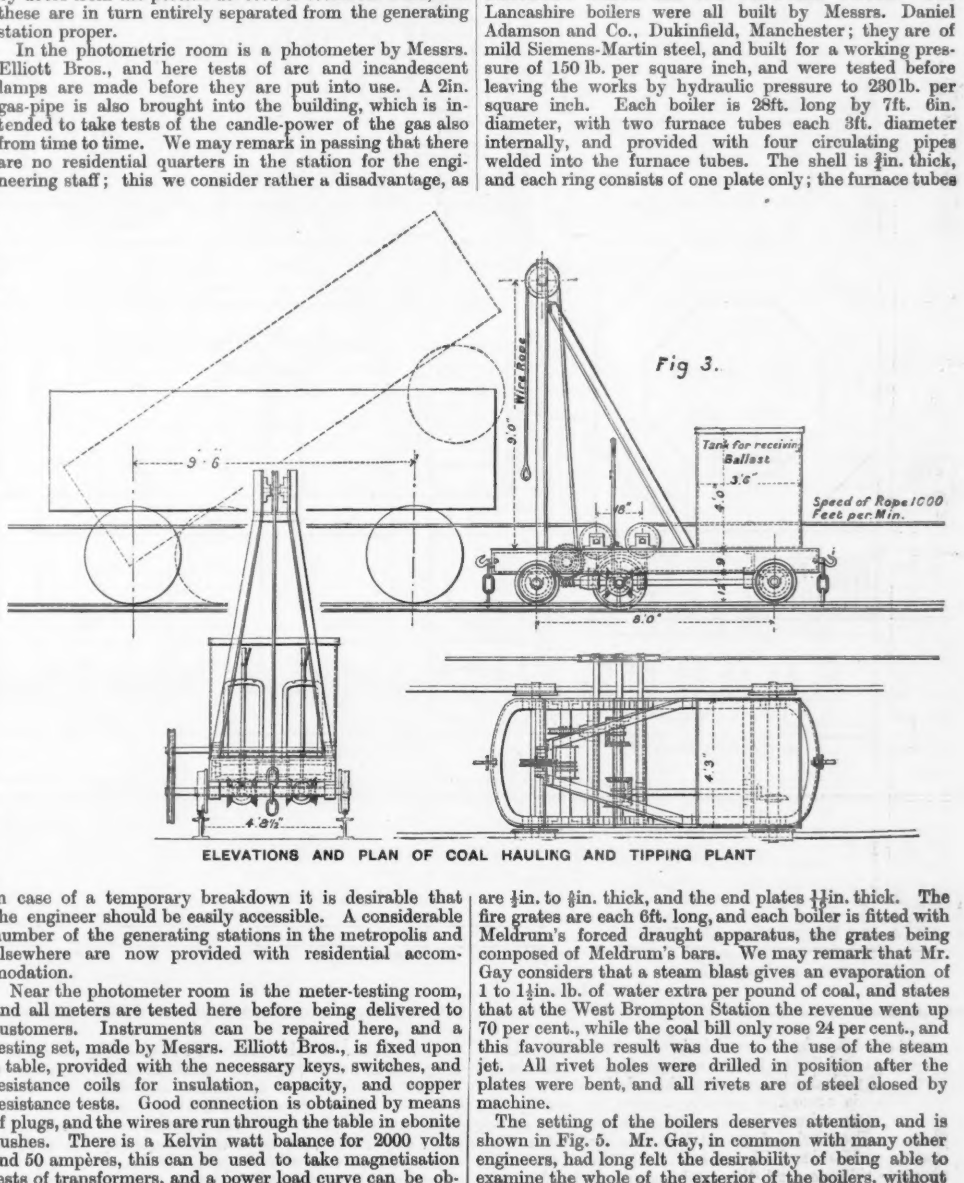
The generating station itself is in Eden-grove, Holloway-road, near the Holloway Station of the Great Northern Railway, and it has been so designed that extensions can easily be made. In Fig. 1 we give a sketch plan of the buildings, in order to show the relative positions of the plant. It will be seen that the engine-room is placed in the centre, and the boilers at present installed occupy the space to the right, and the large chimney shaft is placed so that it will serve for a greatly increased station. Vibration should be avoided by this arrangement, as the space occupied by the moving plant does not abut directly upon adjoining inhabited premises. When it is considered desirable to enlarge the station, the whole of the buildings can be extended towards Holloway-road upon the land belonging to the Vestry, and now occupied, as previously stated, by cottages. The Great Northern Railway passes the back of the building, affording facilities for the delivery of coals, and a siding is carried direct into the works. Turntables are fixed so that wagons can be brought into the boiler-house directly over the coal bunkers.

At the entrance to the works there is a large space for carts to be unloaded, and goods are taken up direct to the stores by means of a crane, the goods themselves never being exposed to the weather. Oil is pumped direct from the barrels on the carts to the storage reservoirs in the building, and this is found to effect a very important saving in trouble of unloading. The offices themselves are well laid out, and are reached directly from Eden-grove. The commercial portion of the rooms is separated by doors from the portion devoted to technical work, and these are in turn entirely separated from the generating station proper.

In the photometric room is a photometer by Messrs. Elliott Bros., and here tests of arc and incandescent lamps are made before they are put into use. A 2in. gas-pipe is also brought into the building, which is intended to take tests of the candle-power of the gas also from time to time. We may remark in passing that there are no residential quarters in the station for the engineering staff; this we consider rather a disadvantage, as in case of a temporary breakdown it is desirable that the engineer should be easily accessible. A considerable number of the generating stations in the metropolis and elsewhere are now provided with residential accommodation.



ELEVATIONS AND PLAN OF COAL HAULING AND TIPPING PLANT

Near the photometer room is the meter-testing room, and all meters are tested here before being delivered to customers. Instruments can be repaired here, and a testing set, made by Messrs. Elliott Bros., is fixed upon a table, provided with the necessary keys, switches, and resistance coils for insulation, capacity, and copper resistance tests. Good connection is obtained by means of plugs, and the wires are run through the table in ebonite bushes. There is a Kelvin watt balance for 2000 volts and 50 ampères, this can be used to take magnetisation tests of transformers, and a power load curve can be obtained instead of an ampère curve; the other standard is a 100-volt Kelvin electrostatic voltmeter. The horizontal scale type of multicellular Kelvin voltmeter is preferred to that with the vertical scale. A mirror galvanometer of the Kelvin astatic type is used with the test table, and a testing set of 200 Leclanché cells is mounted upon oil insulators placed upon shelves. The meters used for the customers are of the Chamberlain and Hookham type, and the charge for current is regulated by the Wright demand meters. The latter instruments are largely in use at Brighton, and the instruments were supplied by the Reason Manufacturing Company.

Next to the meter test-room is the arc lamps and transformer store, and this room is provided with special racks for arc lamp testing, and no lamp is allowed to be connected on to the circuit by a customer until it has previously been tested by the Supply Company. This room is also used for storing transformers and thoroughly drying them previous to use by passing a current through their coils.

The oil store adjoins the lamp room, and contains three galvanised iron tanks, two of which are of 1000 gallons capacity each, for engine and dynamo oil respectively, and the third holds 500 gallons, and is used for cylinder oil. Passing now to the generating plant, we illustrate the general arrangement in plan, Fig. 2. Coal is brought in 10-ton end-tip wagons, and is shunted on to the works private siding; here it passes on to the Avery weighbridge, where the weight is registered; the truck then passes on to the turntable and is dealt with by the hauling and tipping apparatus, shown in Fig. 3. The power is obtained from a rope driven by a small vertical engine, and the gear is of the worm and worm wheel type, so that there is no possibility of danger from slipping or overrunning. The motions are readily controlled by hand levers, placed so as to be conveniently handled by the attendant. The truck is first drawn into the building, the winch is then anchored, as shown, and the truck is then lifted at one end, and the load of coal is shot into the bunker below. The apparatus works very satisfactorily, and saves all the expense of manual labour and cartage. The bunkers are provided with sliding doors below of a peculiar pattern, whereby the door is not jammed fast by the direct pressure of the mass of coal. We have on various occasions described arrangements for dealing with coal, notably that at the Great Northern Railway Company's generating station, but the present arrangement has not previously been applied so far as we are aware. This apparatus was built by Messrs. Craven Brothers, of Manchester, who also built the overhead travellers used in the station.

The boiler power at present installed consists of four Lancashire boilers and two water-tube boilers. The Lancashire boilers were all built by Messrs. Daniel Adamson and Co., Dukinfield, Manchester; they are of mild Siemens-Martin steel, and built for a working pressure of 150 lb. per square inch, and were tested before leaving the works by hydraulic pressure to 230 lb. per square inch. Each boiler is 28ft. long by 7ft. 6in. diameter, with two furnace tubes each 3ft. diameter internally, and provided with four circulating pipes welded into the furnace tubes. The shell is $\frac{3}{4}$in. thick, and each ring consists of one plate only; the furnace tubes are $\frac{1}{2}$in. to $\frac{5}{8}$in. thick, and the end plates $\frac{11}{16}$in. thick. The fire grates are each 6ft. long, and each boiler is fitted with Meldrum's forced draught apparatus, the grates being composed of Meldrum's bars. We may remark that Mr. Gay considers that a steam blast gives an evaporation of 1 to 1$\frac{1}{2}$in. lb. of water extra per pound of coal, and states that at the West Brompton Station the revenue went up 70 per cent., while the coal bill only rose 24 per cent., and this favourable result was due to the use of the steam jet. All rivet holes were drilled in position after the plates were bent, and all rivets are of steel closed by machine.

The setting of the boilers deserves attention, and is shown in Fig. 5. Mr. Gay, in common with many other engineers, had long felt the desirability of being able to examine the whole of the exterior of the boilers, without disturbing the setting, and for this purpose, instead of putting insulating material directly upon the top of the boiler, he has built a chamber above composed of a roof of iron plates supported upon tee irons. The upper surface of these plates is thickly covered with non-conducting composition. Access is obtained to this chamber by means of a manhole. The division between adjacent boilers consists of two brick walls, each 9in. thick, with a 8in. air-space between; this makes a good non-conducting screen, and it is found possible to attend to repairs in any boiler, even while the boilers on each side of it are in full work. It will also be seen that the whole of the shell of the boiler is accessible outside, except, of course, the narrow strip where the shell rests upon the setting blocks. The whole of the fittings are by Messrs. Hopkinson, of Huddersfield, and each boiler has a feed valve at each side, so that the feed supply is in duplicate throughout.

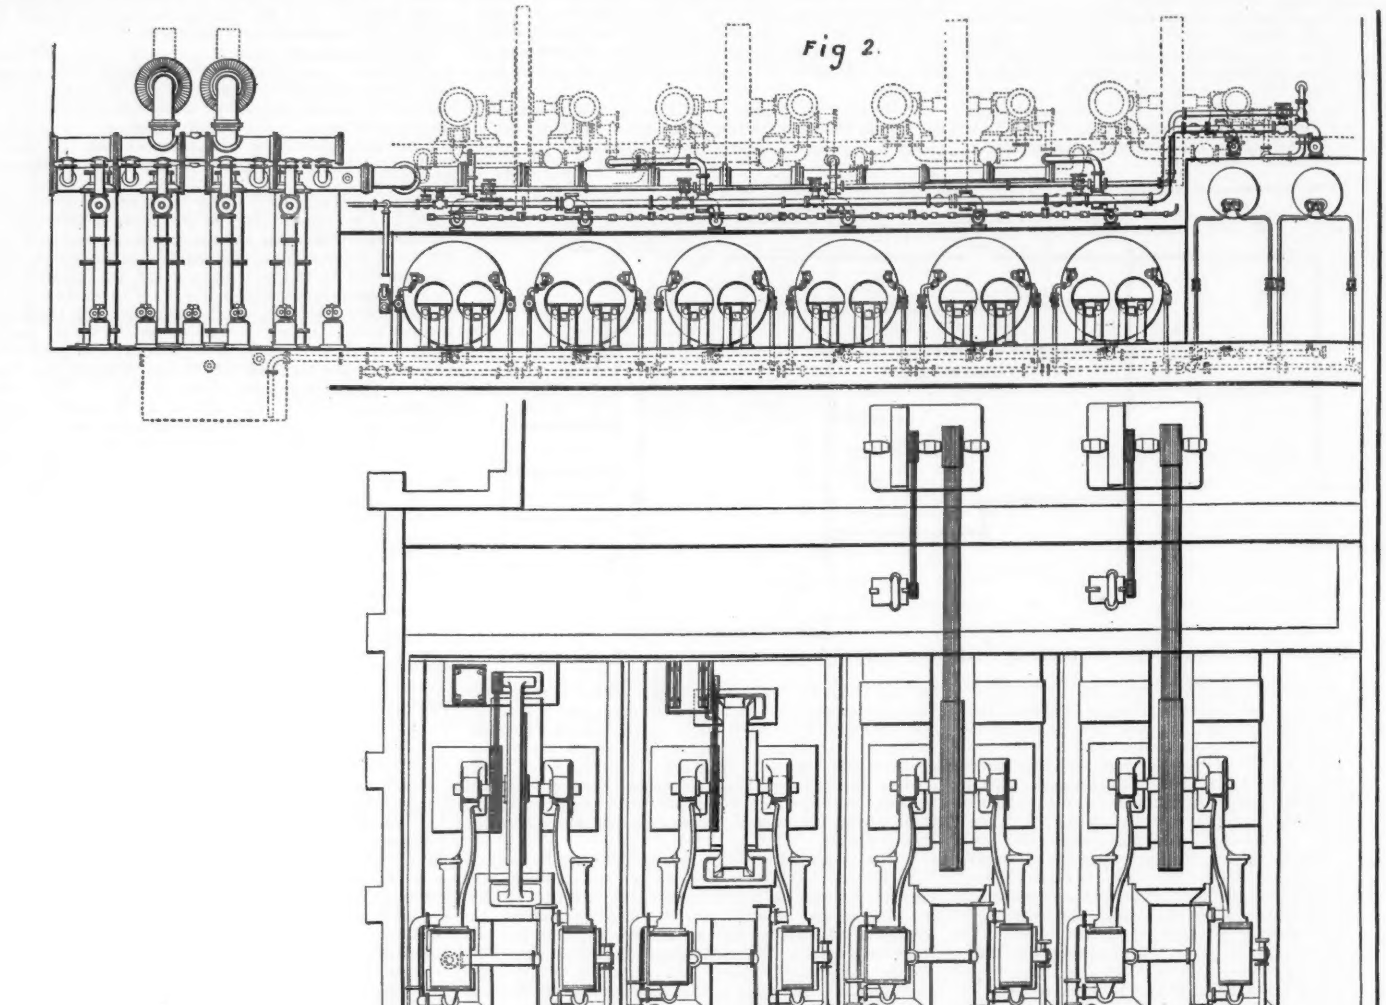


Fig 2.

PLAN AND SECTIONAL ELEVATION OF ENGINE AND BOILER HOUSE, ISLINGTON ELECTRIC LIGHT STATION

The boilers are set 11ft. centre to centre, and the stokehold floor is 11ft. below the railway level. The dampers are not worked by the usual arrangement of weights and chains over pulleys, but by a new method shown in Fig. 4, from which it will be seen that the dampers do not slide but turn on pivots, those of the Lancashire boilers being like doors hinged at one side, while those of the water-tube boilers are of the butterfly-valve type, pivoted in the middle. Each damper is controlled by means of a long rod, and a pair of bevel wheels actuated by means of a lever at the front of the boiler, and this lever can be locked in any position by a locking handle. The whole arrangement gives absolute control over the damper, with exactitude said to be unattainable by the ordinary arrangement, even with a system of marks on the wall. We were informed that the surface of the non-conducting composition above the boilers never rises to a temperature above 20 deg. Fah. in excess of the temperature of the air, and as the boiler-house is very lofty it is much pleasanter than the similar part of many other electric-lighting stations. The evaporation of each boiler with natural draught is given as 5000 lb. of water per hour from and at 212 deg. Fah.; but this is considerably exceeded with the forced draught.

The water-tube boilers were supplied by Messrs. Babcock, Willcox, and Co., and are of the most recent type. The tubes are made according to ordinary locomotive practice; that is, expanded for a short distance at one end; so that the holes in one tube plate are larger than in the other. This allows the tube to be got out, even although covered with scale. We understand that this is the first time this method has been adopted to this type of boiler. All the headers are of pressed steel, instead of cast iron, and there is far better means of access to inspect the tubes. Mr. Gay's past experience has led him to make suggestions which led to these variations. Each boiler has 1600 square feet of heating surface, and 30 square feet of grate surface; and the evaporative capacity of each is about the same as quoted above for the Lancashire boiler.

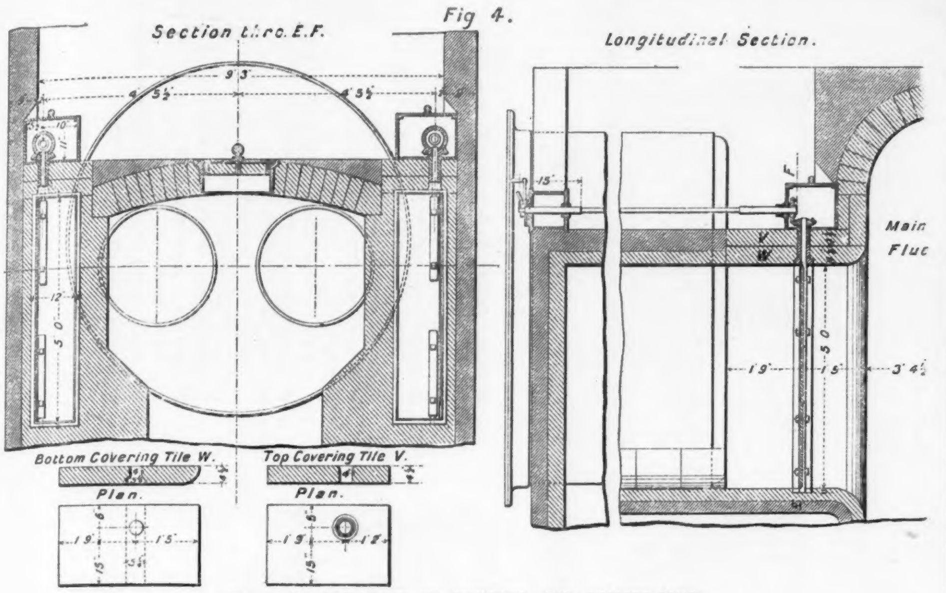

Fig 4—ARRANGEMENT OF DAMPERS AND DAMPER GEAR

Besides the boilers, Messrs. Adamson also supplied the whole of the steam pipes, exhaust pipes, pumps, injectors, feed-water heaters, and water connections. The arrangement of steam pipes is clearly shown in Fig. 1A, the ordinary ring main has not been adopted. Primarily, each boiler feeds one engine, but there is an equalising pipe which connects all these steam pipes together. A diagram of the arrangement is shown in Fig. 1A, the crosses representing stop valves. The actual arrangement is shown in Fig. 2; it will thus be seen that in ordinary work each engine is supplied by its own boiler, and there is little flow of steam along the equalising pipe, but if desired any engine can be supplied by any boiler. All the steam pipes and connections are of steel, with copper U bends to allow of free expansion; these bends are placed in the horizontal plane, and therefore there is no chance of water collecting in them as is the case when they are placed vertically. The exhaust pipes are of wrought iron, with riveted seams and cast iron flanges, the latter appear somewhat heavy, but we understand that the arrangement has been made with a view to a possible future use of condensing apparatus. In one corner of the boiler-house is placed a tank which will be of use for measuring feed-water for experimental purposes, and also for injecting compositions to prevent incrustation.

Mr. Gay has paid the very greatest attention to the question of feed supply. The whole apparatus is in duplicate, so that it seems impossible that any serious breakdown should occur. The feed-water is obtained from the mains of the New River Company, and passes along a main below the future boiler-house, and supplies two large tanks placed on the roof of the stores. Each tank holds about 20,000 gallons, and the water is delivered to the boilers by three Worthington pumps; besides these there are two of Körting's injectors, and the feed pipes are arranged on the ring system. Near the pumps are placed two exhaust steam feed-water heaters of the Withinshaw type, built by Messrs. Lupton, of Coventry, and bye-passes are provided, so that the exhaust steam can be carried direct to the chimney if so desired. The pressure of water in the supply water mains is about 100 lb. per square inch, and relief valves are to be put on the feed pipes and loaded to 155 lb. per square inch.

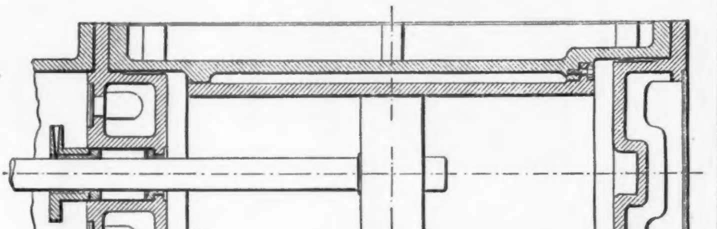

Fig. 7—IMPROVED WHEELOCK VALVE GEAR

The boilers can be blown off into a closed blow-off pit, the outlet of which is provided with a back-pressure valve to prevent the contents of the drain coming back into the pit.

The chimney stack is of ample size for future extensions, and is intended to suffice for sixteen boilers of similar size to those already installed. Eight of these will be placed in the present boiler-house, where there are at present six, and the remaining eight will be placed in the new boiler-house not yet built. The shaft is 180ft. high, of octagonal section, 14ft. diameter at the bottom, and 12ft. diameter at the top, while the external dimensions are 24ft. diameter at the bottom, and 14ft. 3in. at the top. It is built upon a solid bed of Portland cement concrete, 40ft. square by 9ft. thick.

Passing now to the engine-house, we find a fine spacious building, well lighted from above, and having walls faced with glazed bricks, giving the whole a very clean appearance. There are at present installed four complete sets of engines and dynamos, placed as shown in Fig. 2; two of the engines drive their alternators by ropes, and the other two have fly-wheel alternators. All four engines were built by Messrs. Daniel Adamson and Co., of Dukinfield, Manchester, and are of interest as showing the tendency to the use of slow-speed engines instead of high-speed engines direct coupled. In Fig. 6, page 544, we give an illustration of one of the engines, from a photograph; they are compound, horizontal high-pressure engines working non-condensing, and are fitted with Wheelock's expansion gear.

Each engine will develope 250 indicated horse-power, and the makers gave a guarantee that the consumption of steam should not exceed 20 lb. per indicated horse-power per hour. At present we are not able to state what the exact figures are in actual working, but a premium of 5 per cent. upon the agreed price will be paid for every pound below 20 lb. which it is found is consumed by the engines. The principal dimensions are as follows:—

High-pressure cylinder diameter	15in.
Low-pressure cylinder diameter	24in.
Stroke	36in.
Shaft bearings	8in. diameter by 1ft. 6¼in. long.
Shaft body	12in. diameter.
Centres of engines	10ft. 9in.
Crank pin	6in. diameter by 6in. long.
Connecting-rod centres	8ft. 3in. long.
Connecting-rod diameter at crank ends	4½in.
Connecting-rod diameter at crosshead	3⅝in.
Connecting-rod diameter at one-third its length from crank pin	5in.
Crosshead pin	3½in. diameter by 5in. long.
Piston-rod	3¼in. diameter.
Crosshead bore of guide	19½in. diameter.
Crosshead slipper blocks	16in. by 11½in.
Rope pulleys	14ft. diameter; weight 10 tons; 10 ropes 1¼in. diameter.
Speed	95 revolutions per minute.
Piston speed	570ft. per minute.

In Fig. 7 we give sections of the cylinder showing the valves; these are of the most recently improved type, of which Messrs. Daniel Adamson and Co. are the sole makers in this country. The whole of the valves of each pair of cylinders are driven by one excentric, the same excentric being used for driving both the steam and exhaust valves, and fitted with improved gear for giving automatic control of the expansion from zero to 75 per cent. of the stroke of the piston, whilst retaining complete control of the periods of release and compression. The valves are driven by means of levers keyed upon the valve spindles, and they have a vibrating motion, as in the earlier type of "Wheelock" gear, the levers being keyed to the rocking levers and excentrics by adjustable coupling rods in the usual manner; the steam valves are driven from the exhaust valve levers by means of latch links, which engage with hardened steel trip blocks, pivotted to the ends of the steam valve levers; the disengagement of the latch link and trip block is effected by means of cam levers, controlled by the governor or regulated by hand, as the case may be.

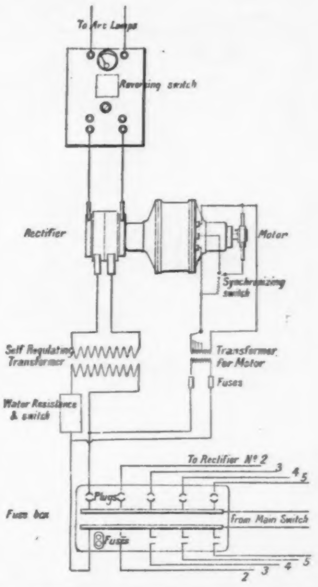

Fig. 8a—FUSE-BOX AND RECTIFIER CONNECTIONS

When disengagement takes place the valves are instantaneously closed by means of helical springs working in a dashpot with a noiseless air-compression cushion. The cams for disengaging the latch links have a defined positive travel obtained by suitable connection with the excentric rod, which is used for driving the valves. The timing of the travel is varied, and controlled by the governor, a resultant action being thereby obtained capable of tripping or disengaging the latch link in any position of the gear, whether it is moving in a forward or backward direction, thus giving complete automatic control of the expansion. The valves and seats are of the flat grid type, giving large openings with small travel and small surfaces for friction to act upon. A toggle joint between the valve grids and spindles gives almost instantaneous opening and closing, with great ease of action under extreme pressures

By this arrangement the valves are allowed to dwell or rest during the periods of exhaust or admission respectively. It will be seen that both the steam and exhaust valves are contained in one chest or port at each end of the cylinder. The seats of the valves are in the form of a plug, which is turned a little taper to fit the bored seats in the cylinders, the valve seats being thus entirely independent of the cylinder casting, enabling spare valves and seats to be kept in stock, and entirely dispensing with wear in the cylinder casting itself. The valve spindles are

Swain Eng

of the Wheelock self-packing type, dispensing entirely with the usual stuffing-boxes and glands. We are informed by the makers that some of these engines have given in regular work one indicated horse-power for 1·251 lb. of coal, and this result is taken from actual work over an extended period, and not from a special test of a few hours only.

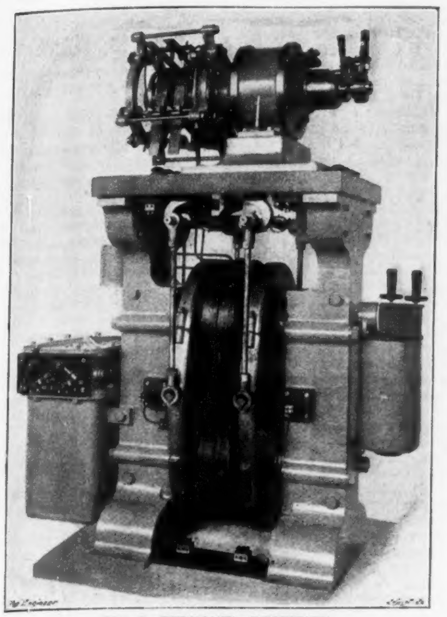

Fig. 8—FERRANTI RECTIFIER

The arrangements for lubrication are very complete, and the oil, after having passed through the bearings, is conveyed by pipes to a well below the floor of the engine-room, whence it is pumped by hand to the filters and used over again. All the steam, exhaust, and drain pipes are carried below the floor level, and each engine rests upon a separate massive block of concrete. The floor girders are bedded upon thick india-rubber pads, and on the occasion of our visit we noticed no vibration. Two of the alternators are rope-driven; these have been built by Messrs. John Fowler and Co., of Leeds, under Mr. Hall's patents, and each has an output of 100 kilowatts, at a speed of 375 revolutions per minute, and will easily maintain a pressure of 2000 volts at full load at that speed. The mean speed at which the armature conductors are passed by the field magnets is about 6000ft. per minute, and the frequency is fifty complete phases per second.

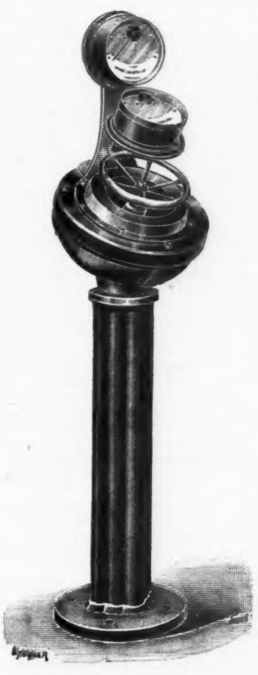

Fig. 10—REGULATOR

The armature is stationary, with an iron core of large section composed of best charcoal iron sheets bolted rigidly between two heavy cast iron clamps, the sheets being insulated from each other, and arranged longitudinally in the same plane with the magnetic fields. The conductor, when at full load, carries not more than about 1710 ampères per square inch of section, and it is composed of copper ribbon of 98 per cent. conductivity, well insulated, taped and fixed in such a way as to present the edge of the strip only to the field magnets, thus rendering the coil quite rigid. The ends of the coil are passed through porcelain insulators in the cast iron clamps, and are fixed to terminals mounted on ebonite, and are readily accessible on the removal of the wood lagging. The entire armature consists of eight segments, held in position around the field by a heavy cast iron frame. The high-pressure terminals are placed under lock and key. The field magnets are the moving parts of the machine, and consist of laminated charcoal iron, this arrangement enabling the best iron to be used without introducing a magnetic joint. There are sixteen poles, and each has its own exciting coil, composed of well insulated copper wire.

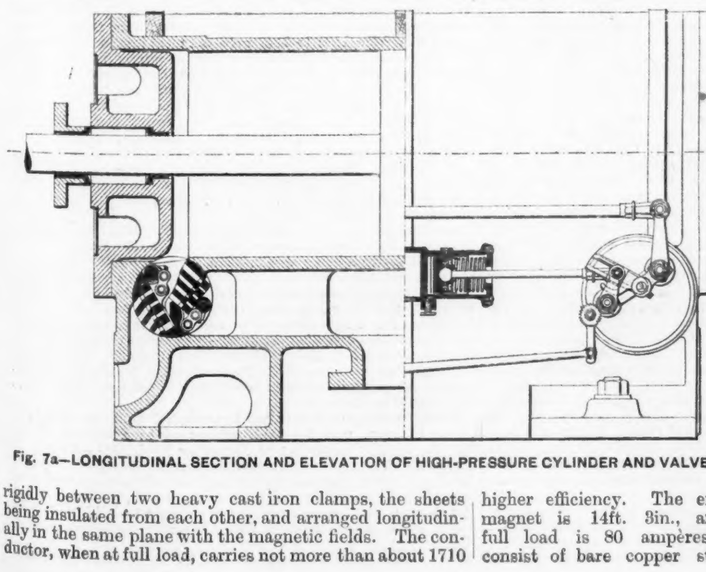

Fig. 7a—LONGITUDINAL SECTION AND ELEVATION OF HIGH-PRESSURE CYLINDER AND VALVE GEAR

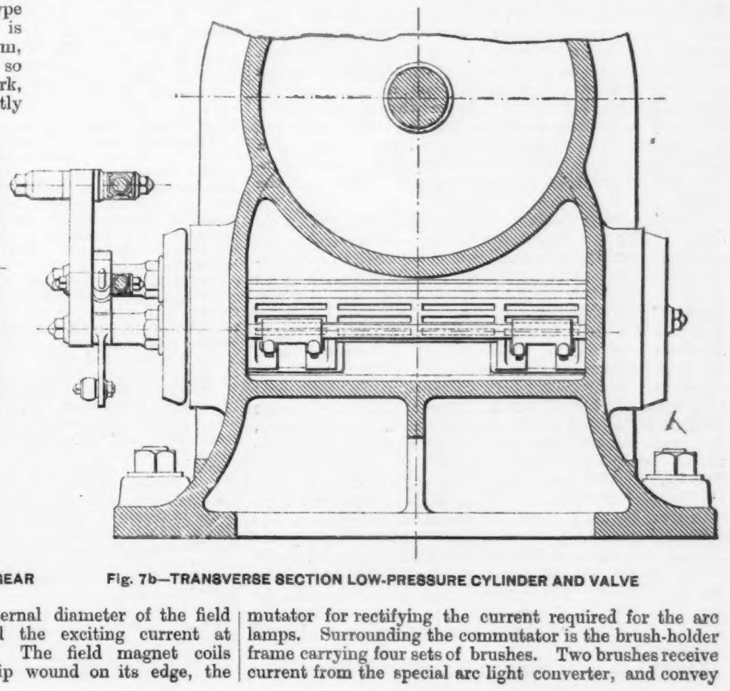

Fig. 7b—TRANSVERSE SECTION LOW-PRESSURE CYLINDER AND VALVE

The above construction is adopted to avoid the eddy currents usual with solid magnets, and the current density is about 720 ampères per square inch of section. Each collector ring is provided with two sets of brushes. The insulator resistance between the conductor and the laminated iron core is 15 megohms, and between the armature and body 10 megohms.

The next machine is a Fowler fly-wheel alternator, similar in construction to those just described; the fly-wheel forms the supporting part of the field magnets, around which the stationary laminated charcoal iron armature is built. The current density is as follows: Armature, about 1800 ampères per square inch, field magnets about 750 ampères per square inch; the speed is ninety-five revolutions per minute and there are sixty-four poles in the field and thirty-two segments in the armature, each having its own coil. We understand that a machine of similar type is now at work at Reading. The guaranteed commercial efficiency is 92 per cent., and the excitation is not to exceed 2 per cent. of the output. Each machine drives its own exciter, which is a simple shunt wound machine giving 50 to 60 volts and 50 to 60 ampères. They were also built by Messrs. Fowler and Co.

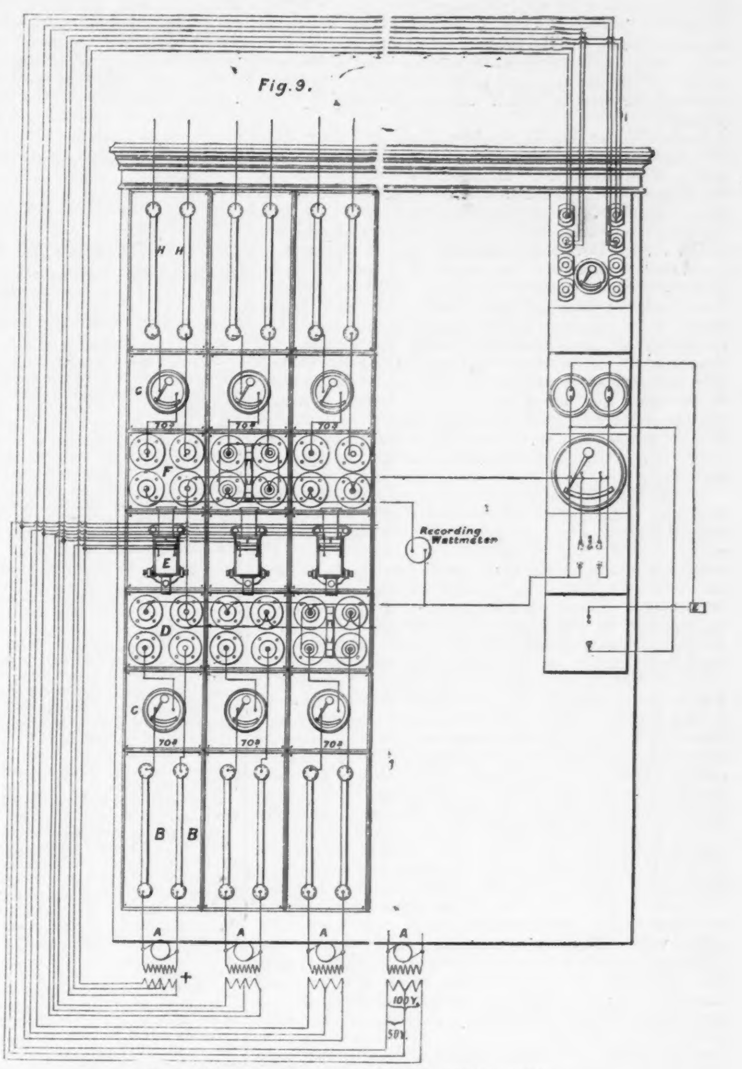

Fig. 9—DIAGRAM OF SWITCHBOARD CONNECTIONS

The fourth machine is a fly-wheel alternator by Messrs. Z. D. Ferranti and Co., and is of the revolving magnet type. It gives an output of 125 kilowatts at 2000 volts when running at ninety-five revolutions per minute. It has sixty-four field magnets and thirty-two armature coils. It is of the same type as was used at Portsmouth and Southport, and we may point out that a type with revolving armature is also built by the same firm, but was not considered so suitable for the Islington work, although it gives a slightly higher efficiency. The external diameter of the field magnet is 14ft. 3in., and the exciting current at full load is 80 ampères. The field magnet coils consist of bare copper strip wound on its edge, the adjacent layers being separated by paper rings covered with shellac and pressed into position, the coils themselves being insulated by heavy fibre washers. We are informed by the makers that there is little fear of short circuiting by water or dirty oil, and the construction would permit of the machine being cleaned if desired with a hose pipe. The exciter for this machine is of the single shunt type, and was built by the Electric Construction Corporation.

With a station supplying arc lights for public lighting, and also private consumers, it was of course possible to employ rectifiers for the public lighting, and these apparatus have been supplied by Messrs. Z. D. Ferranti and Co. We illustrate one of the five rectifiers in Fig. 8, and they are of somewhat similar type to those used at Portsmouth; each consists of a synchronous self-starting alternate current motor, fitted with the necessary commutator for rectifying the current required to excite its own field magnets, and also with a special form of commutator for rectifying the current required for the arc lamps. Surrounding the commutator is the brush-holder frame carrying four sets of brushes. Two brushes receive current from the special arc light converter, and convey it to the commutator, and the other two take up the rectified current when it passes to the switchboard.

The special converter gives a practically fixed current in its secondary circuit, with an electro-motive force varying according to the load on the secondary, so that it is the exact reverse of the ordinary transformer. The primary coils are arranged so that they balance one another on the rocking levers, and move equally towards or away from the fixed secondary coils. Others are so weighted that they are just clear of the secondary coils, when a current of 12 ampères passes through the latter. When the secondary current increases the repulsion becomes greater, and the primary coils move away, and so reduce the secondary current by causing more of the lines of force of the primary coil to be diverted. There is a counterpoise weight which can be adjusted by the attendant.

In the diagram, Fig. 8A, we show a fuse-box arranged for five rectifiers, but the connections for only one rectifier are given. This fuse-box is arranged so that any set can be plugged through a Ferranti oil-type fuse on to the station bus-bars. In putting the plant to work, the fuse and plug are inserted in the fuse-box, the motor, which is of the Brown-Boveri synchronous type, is then run to speed and synchronised, the arc circuit is then put on by slowly closing the water-break switch, and this, by introducing a heavy water resistance, allows the load due to the arc circuit to come gradually on to the bus-bars. The method avoids any variation in the bus-bar voltage. On the arc light distribution board a reversing switch and pole indicator are provided, so as to ensure the running of the lamps may never be reversed. Messrs. Ferranti and Co. claim very great advantages for this system, and it is in general use at Portsmouth, Edinburgh, Cardiff, Tunbridge Wells, and elsewhere, besides the present station.

The main switchboard is placed upon a gallery at the end of the engine-house, whence the whole of the plant can be perfectly seen, and signals are transmitted to the engine and dynamo attendants by means of a ship's telegraph of the Willis type, made by Messrs. Elliott Brothers. We give in Fig. 9 a diagram of the switchboard connections. It consists of nine sets of slate panels, and is arranged on the Lowrie-Hall system, consisting of double-pole double-break switches of the plug type, the fuses being also of the Lowrie-Hall pattern, as used at West Brompton, and many other places. Referring to Fig. 9, the alternator is shown at A; the lowest slate panel carries the fuses B B in the alternator circuit. Above these is the alternator ampèremeter C, above that is the alternator switch D, which is connected with the main omnibus bars behind the board; above this is the alternator pilot voltmeter—one of Lord Kelvin's multicellular vertical instruments — supplied with current from the special transformer T below. Above the voltmeter is the circuit switch F connected to the omnibus bars at the back of the board, then the circuit ampèremeter G, and at the top the circuit fuses H H. The panel which is used for synchronising is shown to the right separately, and synchronising is effected by the use of two lamps in the usual way. There is a separate board, which is not illustrated, used for the arc lights alone, and this enables any particular circuit of lamps to be fed from any machine. The potential is regulated through the exciters from pillars in the gallery, and one of the pillars is shown in Fig. 10.

Considering the whole station, it no doubt looks very large for the power already installed; the approximate cost, inclusive of the site, which will accommodate plant of three times the capacity, was £85,000. This, therefore, means a high capital cost per kilowatt installed, but this will speedily become normal when more plant is put down. Space will not permit of a description of the outdoor work, such as cable laying, but we hope to deal with this on a future occasion.

THE BATH AND WEST OF ENGLAND AGRICULTURAL SHOW.

THE annual exhibition of the Bath and West and Southern Counties Society, which is being held this year at St. Albans, was opened on Wednesday last in charming weather, and will remain open to the public until Monday. The implement and machinery department occupies about the same area as in recent years, although in point of numbers the implements fall somewhat short of those exhibited at the shows of 1893, 1894, and 1895, reports of the last of which we published last June. Taken as a whole, however, this department is thoroughly representative, and forms one of the most attractive features of the show.

Traction and portable engines are exhibited by Messrs. John Fowler and Co., Leeds; Messrs. Ruston, Proctor, and Co., Lincoln; Aveling and Porter, Rochester; J. and H. McLaren, Leeds; Hornsby and Sons, Grantham; William Allchin, Northampton; Ransome, Sims, and Jeffries, Ipswich; Marshall, Sons, and Co., Gainsborough; Barrows and Co., Banbury; Charles Burrell and Sons, Thetford; Robinson and Auden, Wantage; W. Tasker and Sons, Andover; Richard Garrett and Sons, Suffolk; Wallis and Steevens, Basingstoke; E. T. Humphries, Pershore; Clayton and Shuttleworth, Lincoln. Most of these exhibits are of well known standard patterns. We may, however, call attention to a 10-horse power road locomotive with 5-ton crane attached, shown by Messrs. Fowler, which has been constructed for Messrs. Cattermole, of Islington. This engine, which we hope to illustrate next week, is mounted on springs, has specially wide tires on the front wheels to carry the load on the crane, and is provided with a powerful screw brake to act on the inner surface of the rim of the driving wheels. These wheels are provided with the usual crossbars, but holes have also been drilled in the rim for affixing wood blocks when the engine is required on paved roads.

Oil and gas engines are exhibited by, amongst other firms, Messrs. Crossley Brothers, Messrs. Tangyes Limited, T. Green and Sons, Holmes and Sons, Norwich, Clayton and Shuttleworth, Hornsby and Sons, Fielding and Platt, James and Frederick Howard, Bedford, and the Campbell Gas Engine Company. The Central Cyclone Company, London, has an extensive exhibit of its well-known "Cyclone" pulverisers and disintegrators, one of the latter of which is said to be the largest attrition mill yet constructed and is capable of dealing with as much as 10 tons of material per hour. Messrs. J. and H. MacLaren show an 8-ton traction wagon, mounted on springs, having a screw brake which can be actuated by a handle at the side. Amongst the dairy machinery department some new machines are shown, and plenty of evidence given of the growing importance attached in the United Kingdom to this class of mechanical methods of carrying out old processes which are now inferior to and dearer than the new. To these and to other exhibits we must refer in another impression.

LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

THE ORIGIN OF THE BESSEMER PROCESS.

SIR,—I have delayed answering the criticisms on my address, as President of the American Institute of Mining Engineers, on the "Invention of the Bessemer Process," until I could carefully consider the objections urged against the claims of William Kelly, and especially until the "argument by abuse" had been exhausted. The question at issue is one of fact, to be settled by the rules of evidence, and not by abuse or denunciation or the demolishing of "claims" that were not advanced by me. I have carefully read every written and published word in reply that has come to my attention, and have as carefully reconsidered all the evidence offered, as well as other that has been brought to my notice. This has only served to strengthen the conviction, reached after careful investigation more than twenty years ago, a conclusion in which I was at one with many of the most prominent steel and iron makers of the United States at that time, viz., that William Kelly was the inventor of what Holley described as the essential feature of the Bessemer process, which was for many years known in this country among many steel and iron makers as the pneumatic or Kelly process.

And as so many things have been disputed which I did not assert, may I state just what I did claim in my address?

(1) Accepting the definition of Holley, I claimed that the essential feature of the Bessemer process was "the decarburisation of crude cast iron by the air blast in a vessel independent from the blast furnace or furnace in which it was melted, and without the application of external heat."

(2) That the invention set forth in the patents under consideration of both Bessemer and Kelly was covered substantially by this definition.

(3) That Kelly, and not Bessemer, was the original inventor of the process so far as it is covered by this definition.

In proof of this claim I adduced:

(1) The statements under oath of twenty-two persons taken in the interference case between Kelly and Bessemer in 1856-57, who testified of their own knowledge that in 1847 and 1851, and later, Kelly described and practised this invention.

(2) Decisions of the Commissioner of Patents of the United States in at least two cases, in which it was decided, after extended hearings and investigations, that Kelly, not Bessemer, was the original inventor.

(3) The statement under oath of A. L. Holley that he considered Kelly's invention the first practical development of the process.

It will be noted that all of this evidence is either the decisions of sworn officials, or is given under oath at legal hearing, when false swearing would be both moral and legal perjury. In discussing Kelly's claim to be the original inventor, I purposely and vigorously confined myself to this evidence, all of which is a matter of record and not of memory.

Just here let me say that I have no desire, nor have I attempted, to "whittle down the Bessemer process," nor to sum it up in the words "blowing air into iron." If the question of the invention in its entirety of the Bessemer process as it is understood to-day were the point at issue, Sir Henry Bessemer is certainly not its sole inventor. He did not invent the Mushet feature, the use of the triple compound; and the production in the United States of as much as 4,160,072 tons of cast steel ingots in 1892—not 1872, as Sir Henry states—would have been impossible without Holley's inventions for quick working. I purposely and properly confined my claim for Kelly to what has been called the pneumatic feature, and which Holley characterised as the essential feature of the process.

What is the answer of my critics to my claims? To the first it is that these men did not know what they were talking about; that they were unworthy of belief; that their testimony was "vague" and has been discredited.

I reply that on no single statement of fact has the testimony of one of these men been impeached or discredited, though the opportunity was afforded Bessemer so to impeach this testimony, both when the patent was originally granted to Kelly in 1857, and when the application for the re-issue of his patent was before the Patent-office fourteen years afterwards, in 1871.

In the interference suit in the Patent-office between Kelly and Bessemer in 1856-57, Bessemer was represented by the late Mr. R. H. Eddy, the attorney who secured his patent. This attorney, in a letter dated February 26th, 1857, professed his ability to show that "Kelly did not make the invention." The only evidence submitted in Bessemer's behalf to justify this assertion, so far as I have been able to ascertain, was a copy of the *Artisan* of September 1st, 1856; of the London *Times* of August 14th, 1856; and of Bessemer's English patent of October 17th, 1855, No. 2321. The only claim made for this evidence was that it proved that Bessemer made his invention before October 17th, 1855. There is not in the files at Washington, so far as I can discover, one word of testimony to show that "Kelly did not make the invention." There is not a word of testimony, and never has been, to impeach the veracity of Kelly's witnesses, and when on April 13th, 1857, the Commissioner of the United States Patent-office decided the question of priority of invention in favour of Kelly, and ordered a patent to issue to him unless an appeal was taken by Bessemer within sixty days, no appeal was taken, and Bessemer allowed the decision of the Patent-office in favour of Kelly to stand unchallenged, at least in the only legal way in which it could at that time be questioned.

In a word, the testimony of these men as to the facts set forth in their affidavits was uncontradicted by competent testimony at the time, and is to this day, after forty years. It is not vague, and if the testimony is one-sided, as Sir Henry asserts, it is his fault. He had his day in court, his privilege to cross-examine, and his right of appeal, and he exercised none of them. Under such conditions it is simple justice, and strictly in accord with the rules of evidence to assume that these men told the truth. If they did, Kelly invented this process in 1847, at least seven or eight years before Bessemer's earliest date.

My second line of proof was the decisions of the United States Commissioner of Patents: first, in the interference suit in 1856-57; second, in Kelly's application for an extension of his patent in 1871.

The wording of these decisions, so far as relates to the point in question, was as follows:—In 1857 the Commissioner said: "It appears that by the concurrent testimony of numerous witnesses Kelly made this invention and showed it by drawings and experiments as early as 1847, and this testimony appears to be reliable in every respect. . . . Priority of invention in this case is awarded to said Kelly." In 1871 the Examiner reported: "Kelly's own statement of the history of his invention is full and clear, and when taken in connection with the statement of the witnesses, seems to be both intelligible and truthful." These two cases are, so far as I am aware, the only times when priority of invention has ever been directly or indirectly submitted in the United States to a legal or quasi-legal decision, and the decision was against Mr. Bessemer in both cases.

The answer by my critics, when they meet this point at all, is that they have but little respect for the decision of our Patent-office and judges; that is, these critics not only abuse the plaintiff, his counsel and witnesses, but the court as well. In such cases it is generally regarded that the defendant has a very bad case. I am aware that the decisions of our Patent-office and courts do not run in Great Britain, but they do here, and have force. Under these decisions the patent of Bessemer having been superseded and made invalid, so far as the Patent-office was concerned, by the Kelly patent, it may be said that in a certain sense not one ton of steel made in the United States was ever made under the Bessemer patent in question. It was made under Kelly's patent, which the Patent-office had decided to be the valid one, and after the extension of 1871, Bessemer's patent having expired, and Kelly's being extended and being the only one in existence, all steel was made under it until it expired in 1878, and Kelly was paid royalty.

(3) In answer to my claim that A. L. Holley regarded Kelly as the original inventor, the answer is that this is not true, and that in making the assertion I am "throwing mud" upon the reputation of Alexander Lyman Holley. Extracts from letters of Holley are quoted against me.

In the appendix to my address before the American Institute of Mining Engineers I give in full an affidavit of Holley's made in 1871. Question 9 in the affidavit and the answer were as follows:

"(9) What do you consider the value of the invention of Mr. Kelly in its relation to the pneumatic or Bessemer process as at present practised?"

Answer:—"I consider Kelly's invention the first practical development of the pneumatic process, and it has been so recognised by the owners of the combined patents covering this process."

If any man in the world knew both sides of this controversy Alexander L. Holley was that man. He knew all the facts; he was fully competent to give an intelligent decision on the merits of the case; he was an able engineer, he was an honest man. He declared under oath in 1871, when the subject was fresh in his mind, that he considered Kelly's invention the first practical development of the pneumatic or Bessemer process. If Holley was competent to decide this question, and if he knew the facts, and no one dare deny either, there is no escape from the conclusion that Kelly's invention was the first practical development of this process.

A correspondent quotes in *Engineering* a letter of Holley's to show, "what he had to say on the claims of Kelly as a first inventor." There is not one word in that letter that contradicts the position I have assumed. Indeed, it confirms my position. Mr. Holley says, for example: "The patent of William Kelly, of Kentucky—controlled by Mr. Ward and his associates—for refining crude iron by blasts of air, antedates the Bessemer patent in this country." It was this patent that covered the invention which Holley declared to be "the first practical development of the pneumatic process."

In this letter of Holley, Bessemer is nowhere described as the inventor of the process, but as the "perfecter and introducer." "It is proper to remark here," said Mr. Holley, and the correspondent puts it in italics, "that to Mr. Bessemer is awarded in this country the chief credit for perfecting and introducing the process that bears his name here, and all over the world." This does not say the "inventor;" nor does it give him the "entire credit," but the "chief credit," for perfecting and introducing the process. He even shares this with others in Holley's mind. There is nothing in this letter of Holley to even throw a doubt on the statement in Holley's affidavit, that he considered "Kelly's invention the first practical development of the pneumatic process."

I might rest my case here. Indeed, I have been strongly urged to do so as a "matter of courtesy" by some of the most prominent metallurgists and steel makers of this country, who are aware of the strength of certain evidence in my possession to which I have not even referred. Simply as a matter of courtesy, and not that I have no answer, I have concluded to take this advice and not answer in detail Sir Henry Bessemer's letter, except briefly on two points.

(1) The "one-tuyere-vertical-blowing-downward" converter, of which Sir Henry makes so much as the "first converter," was not Kelly's first converter, but the first built at Cambria Ironworks, and was so described by me. Mr. Kelly describes his first converter as follows:—

"The first converter used at the Suwanee furnace was a square brick structure about 4ft. high. Inside, the converter was cylindrical, about 15in. in diameter, with a concave bottom, in the centre of which was a tile perforated with small holes for tuyeres. In this tile was a small air chamber into which the blast pipe entered." Mr. Kelly states that the converter charges in this vessel were 100 lb., but he was troubled with weak blast, as he was in the six or seven other converters he built on a somewhat similar design, the metal clogging the tuyeres, and he was led to place tuyeres in the side near the bottom. He also had the self-same trouble with his iron that Bessemer had.

(2) The impression is conveyed in the replies to my address that mine is the only discordant note that has ever been heard in this chime of universal praise to Bessemer. I have already quoted what Holley and the owners of the combined patents in the United States thought and said. If one acquainted with the facts had been asked who from 1860 to 1870 were the most intelligent and most prominent metallurgists and iron manufacturers in the United States, among the first dozen would have been named Jas. Park, jun., of the Black Diamond Steel Works, Pittsburgh; Capt. E. B. Ward, of Detroit, Michigan; D. J. Morrell, of the Cambria Ironworks; Bernard Lauth, the inventor of cold rolled shafting; and Wm. M. Lyon, of the Sligo Ironworks, Pittsburgh. Each of these is on record as expressing the belief that Kelly, not Bessemer, was the inventor of the process. Mr. Park, in a lecture in 1872, said, "To Mr. Kelly, of Pittsburg, justly belongs the honour of having been the first to discover . . . . the great principle of the pneumatic or Bessemer process."

All through the years since 1857 Kelly's claim has not been allowed to slumber, but has again and again been restated.

As this letter is being written, Mr. Wm. Metcalf, formerly of the Crescent Steel Works, a gentleman who has been president both of the American Society of Civil Engineers and the American Institute of Mining Engineers, has published a work on "Steel," in which, after briefly referring to Bessemer's desire to make steel for guns and his invention, he says:—"At about the same time or a little earlier Mr. Kelly, of the United States, devised and patented the same method. Both of these gentlemen demonstrated the potencies of their invention, and neither brought it to a successful issue.

In this connection it may not be amiss if I quote the words of Zerah Colburn, who has been summoned as a witness by my critics. In THE ENGINEER of December 23rd, 1864—I quote at second-hand, as I have no copy of the original—he says, "It should be stated here that the first experiments in the conversion of melted cast iron into malleable steel by blowing air jets through the mass in fusion appear to have been made in 1847 by William Kelly, an ironmaster at the Suwanee Furnaces, Lyon County, Ky., United States.

"It is notorious that the conversion of iron in this manner at first required great experimental knowledge to make it successful, and Kelly, no doubt, soon found what difficulties were in his path. In June, 1857, however, after Mr. Bessemer had obtained an American patent, Kelly, having conclusively proved his priority of invention, also received a patent, in a form which virtually annulled that held by Mr. Bessemer for the States. It would be natural to say that there was an evident injustice in ranking an abandoned experiment before an invention which, now at least, has become successful."

It is but just to Mr. Kelly to state that he denied abandoning his experiment.

Let me say, in conclusion, that I have no desire to detract in the least from the credit that is justly due to Sir Henry Bessemer. Holley was right when he gave such generous praise to him as the "perfecter and introducer" of this process. His mechanical appliances for the working of the process are deserving of the highest praise, as are the persistence and intelligence with which he set himself to work to make the process a success, when, as he and Longsden so graphically state, the process was "pronounced by the iron trade a complete failure," and when the largest iron manufacturers in Great Britain "who had already negotiated terms for the use of the process, joined in its condemnation and abandoned all ideas of experimenting therewith." Indeed, it was not until 1863 that the first royalty was paid by John Brown and Co., the first licensees who got to work successfully in England. It is to this persistence and intelligence that much, not all, of the final success of this process in the world was due. JOS. D. WEEKS.

Pittsburgh, May 14th.

PERMANENT WAY.

SIR,—The "giant" referred to by your correspondent "Four-foot," in last week's ENGINEER, happens to be an old acquaintance of mine, and I am able to tell you some little about him also. The poor fellow has too often found out that "ordinary men's heads" do "wobble about," and that their understandings are not always to be depended on either, and so far from feeling now "a security he never enjoyed before," as "Four-foot" says, he hardly ever goes through any unusual performance without a feeling of great trepidation.

At one of the "giant's" performances he carried me also, as well as his clubs, when, unfortunately, "the heels of his boots"—although "deep"—managed to slip over the smooth heads of his supporters, and we all came to grief. I was not much the worse for the mishap when I came to myself again; but, Mr. Editor, you should have seen the giant as he lay overturned, and ignominiously kicking his heels high in the air. I lived to tell of this accident, as I could also of many others, some of which happened only very lately.

Mr. "Four-foot" must bear in mind that our "giant," although near a hundred years old, is still growing and waxing in strength, and, in response to the calls of an exacting public, is getting more and more presumptuous every day, although he confesses to feeling some little anxiety in executing unusual feats all the same. I may tell you, then, that he does not consider—as "Four-foot" would have you believe—that he is so ably supported by his assistants now as formerly. On another occasion of an extraordinary exhibition of his, applauded to the echo by his numerous patrons, all of a sudden both himself and his assistants, together with the chairs upon which they sat—cushions and all—and even the very floor of the stage upon which they were planted, were sent right and left pell-mell in all directions, and such a commotion produced that Goliath of old, or Samson at his best, would have been quite unequal to producing anything so disastrous.

Now, Mr. Editor, it is very plain that our "giant" must stop growing in bulk, and curb his disposition for exhibiting his increasing strength, and rather take to his business more quietly, or his assistants and supporters—chairs, cushions, and all will have to give place to others better able to withstand his antics. If not, he will surely kill somebody "as *is* somebody," yet; and it may happen to be the bishop that "Mr. Punch" once suggested might possibly become involved in such a disaster, when, as he supposed, the matter would be considered as it ought to be, and accidents on railways prevented.

Just a word in another direction, Mr. Editor, if you please. I agree with Mr. Fforde that mechanical work is rapidly supplanting hand labour, and this is all in the right direction; but a line will have to be drawn where a "cheap and nasty" result comes in; especially where it may affect the lives of human beings. In the column headed "Railway Matters," in last week's ENGINEER, I read that out of fifty-seven derailments of trains, of permanent way origin, occurring in the U. S A. during one month, thirty, or more than 50 per cent. of them remained "unexplained." A machine "depositor, &c.," would be charitable enough to cover up a multitude of imperfections and faults, which would otherwise be discovered, and go a long way toward reducing a not very creditable result of unknown causes. The mere deposition, spreading and trimming of ballast, is not of itself sufficient to ensure immunity from accident, and is only of use when the contending forces brought into play are, unfortunately, from whatever cause, allowed to be so equally balanced, that a pound or two more or less of resistance would be acceptable to turn the scale in favour of safety. This value of that part of ballasting is of universally unwritten acceptance, and it follows that even the little help it would be on such occasions as I have above described, is—more's the pity—not much thought of. In all I say about this, I have as much the interest of my own precious self at stake as the life of any other person.

I learned the practice of platelaying in my youth from a good navvy, on the first mile of the first branch that was ever made from the old London and Birmingham line, and that, too, as a pastime, before cricket and football became such popular means of letting off the superfluous steam of muscular Christianity. Since that time I have performed every operation pertaining to it with my own hands, over and over again, instructing numerous gangs of unskilled labour to do the same work effectually. Beside this, I have laid the whole matter in its naked truth to heart, and therefore I feel that if, as Mr. Fforde suggests, my "exposition" should be taken by anyone as a reflection upon himself, instead of seeing in it a something to be inwardly digested, to get what possible good there may be in it out of it, I can only say that I am very sorry for that individual. Mr. Editor, I would not afford as much ink as would dot an "i" upon this paper on any subject that affected the pocket only; but the meanest life—which might even be my own, or one near and dear to me—to be sacrificed to a "practice" which is avoidable, and which, on due consideration, ought never to have existed at all, and besides is roundly condemned by a responsible Government engineer, justifies me or anyone in coming forward with any honest suggestion which can be shown to be the result of experience and considerable thought.

I was greatly pleased with the observations contained in Mr. W. M. Acworth's letter last week, recording a very important and interesting interview between that gentleman and some American railroad magnates; and I wish to refer to that account, as far as it may be taken in relation to the elasticity and rigidity of a permanent way. One of your correspondents, a little while ago, suggested the advantages of solidity, when soon afterward another endeavoured to show that any approach to such a condition was undesirable, and that the nearer a solid and rigid construction was obtained the worse for the road itself, and the rolling stock too.

Upon this head I might say a great deal which possibly would be interesting to some of your readers, and with your permission, Mr. Editor, I may do so some day, but now it would lead me too far from the subject in hand. I will content myself, therefore, with saying that I have always advocated the abundant sleepering of the permanent way, and that only the facility offered for packing should put any limit to it; and that the rail as well should be so heavy and so formed as to be liable only to the least possible amount of depression between sleeper and sleeper. I have long considered, too, that ballasting should take a new departure, and that the additional expense of adding even a hundredweight of iron per yard to the rail would be the best paying outlay of capital ever contemplated among all the many improvements proposed for permanent way.

Now, Mr. Editor, I do not for a moment think that rails will in our day—at all events in my time—ever be rolled of 202 lb. per yard; but I do think that it will soon be found advantageous to stiffen them very considerably, and that this will be effected by adding to the number of sleepers, or increasing the weight of and altering the form of the rail itself, or both together; for which improvements—or I may call them innovations—I declare there is no end to the advantages which might be adduced.

As I have inferred in my recent letters, so I say now, this is not a matter of inspectorship as toward the public, but involves another direction of the profession. And in conclusion, I will say that a consideration of it would be found to pay; and that, after all, is something in its favour. J. W. WILKINS.

May 26th.

SIR,—The rough sketch of the dialogue given by Mr. W. M. Acworth, page 518, is especially interesting to me, as it so exactly agrees with several conversations which I had with American railroad officials when travelling on their lines in 1893.

On each occasion upon which the subject of permanent way was discussed, I was informed that "the English system of rails and chairs would not do for their heavy and fast traffic," and on one occasion I was shown a heap of the English pattern of rails and chairs which had been tried experimentally and afterwards taken up, and there was no overcoming the fact that many of the chairs and some of the rails were broken, which was stated to be the reason for their being removed from the track.

In consequence of these conversations, I took especial notice of the running of the American trains, and of their permanent way. The majority of the rails were 60ft. in length, 90 lb. and 100 lb. per yard, and were supported by no less than thirty large cross sleepers; in some instances there were even more sleepers, and the permanent way almost amounted to a continuous bed of sleepers, having very little ballast between each one. The "riding" on the engines, and also in cars, over the American tracks was most remarkably steady and smooth, and there could be no question that their system of permanent way gave far more elasticity, and caused far less noise than is experienced in this country.

In England it is the general opinion of railway engineers that "a first-class road cannot be made with flanged rails spiked to cross sleepers." It is not to be expected that English practice will be changed for many years to come; but during the past three years I have several times suggested that it would be a great advantage if one of the large English companies would lay down at least one mile of American track upon one of the fastest and hardest worked portions of railway in England; the practical results obtained would very soon prove the advantages or disadvantages of the two systems.

American trains carried on bogies and provided with central buffers, weight for weight, have less resistance per ton than English carriages with rigid wheel base and side buffers. No doubt, to a great extent this accounts for some of the work performed by their engines.

We hear from America what their engines can do with their trains of a certain weight, but there is no means of ascertaining what the same engines would do with an English train of similar weight, but having more resistance.

CLEMENT E. STRETTON.

Saxe-Coburg House, Leicester, May 23rd.

SIR,—It is much to be regretted that Mr. Acworth seems to have lost his presence of mind. Possibly he was overawed by a president and a vice-president. Had he kept his head he would have asked these gentlemen to explain why it is that on the splendid American roads of which they spoke it is so difficult to keep a train. The derailments which take place in the United States—after making allowance for augmented mileage—are enormously more numerous than in this country. C. TRENAIL.

Ipswich, May 26th.

SIR,—As Mr. Acworth condemns the English system of railway chairs, and deems much better the American plan of placing the rails directly on wooden sleepers, will he explain why some of the best of the American lines are now interposing steel plates between the rails and the sleepers? See letter of "Railbed" in THE ENGINEER of January 17th? ANGLO.

Leeds, May 25th.

THE PROBLEM OF SPEED.

SIR,—I beg to offer you my best thanks for the publication in your last number of a translation of my paper "The Problem of Speed," and for your kind remarks thereon.

Allow me, at the same time, to take exception to a phrase in your editorial, "It is noteworthy that the speeds of his—Normand's—torpedo vessels, at the beginning of the series, fall far below those which were being obtained in this country at the same time."

That such is the case for trials made in England under unspecified conditions of weights I am quite ready to admit, since you say so, but it is equally true that ever since I began to build torpedo boats their speed was always superior to that of foreign ones, when tried on the same measured mile, and under the same conditions.

It was so as early as 1878, and the superiority found on trial—about 1 knot—was more than doubled on service, on account of the much smaller consumption of coals.

In the Spanish trials of 1888, a small boat of mine, the Barcelo, delivered two years before at the very modest speed of 19·50 knots, had to compete with seven larger English-built boats, of which two had an official speed of 26·3 knots, two of 23·03 knots, one of 20·5 knots, and two of 20·16 knots. The Barcelo gave the greatest speed in a sea run of 68 miles, see *Engineering*, vol. xlvii., page 381.

Some Russian experiments gave the same results. The Avant-Garde to which you allude carried very heavy weights, more than double of those of the Coureur—an improved Ariete. Now the speed of the Coureur was not 26 knots, but 23·53 knots. One of the boats mentioned in the table at the end of my paper, the Lancier, carried a weight of artillery, torpedoes, coals, men, stores, &c., equal to $\frac{1}{3\cdot8}$ of her displacement, more than double the proportion in the destroyers. Taking this, and also the small displacement of the Lancier into account, is not the speed of 25·79 knots proportionally higher than those of 27 and 28 knots attained two years later by the destroyers.

But nothing better than the Forban shows the immense influence of lightness on speed. There, the French Admiralty, by way of experiment, reduced the extra weights on trial to the same proportion as in the destroyers, about $\frac{1}{7\cdot8}$ of the displacement, and the result, in spite of the small displacement and the low revolutions, was over 31 knots. She still holds the record. Now, for many years, the trials are made in France with a weight of coals corresponding to a certain steaming distance, this weight being deduced from one or two preliminary trials of long duration. For instance, the weight carried by the Lancier corresponds to 2000 nautical miles at 10 knots—the consumption speed is now increased to 14 knots. It will be most interesting to see the result of the adoption of the same very reasonable measure by your Admiralty.

The object of this letter, Sir, is not to cast any shade on the very high and duly deserved reputation of English builders of high speed vessels. Some of them are very good friends of mine, and I do not forget that the real inventor of those high speeds is an Englishman, Mr. Thornycroft. I only wish to prove that it is not only recently that we have been able to compete with English engineers. A. NORMAND.

Havre, May 25th.

THE JENNY LIND: A LINK IN LOCOMOTIVE HISTORY.

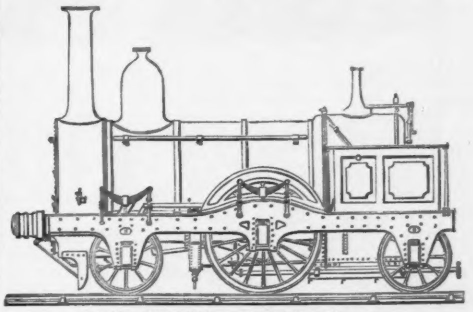
SIR,—In the interests of correct locomotive history it certainly is very greatly to be regretted that, at the conclusion of Mr. Tomlinson's presidential address, Mr. David Joy did not make any mention whatever of the record which he gives in his letter, page 527.

Turning to the printed copy of the excerpt minutes of the meeting, it will be found that on page 195 Mr. Tomlinson stated:—"E. B. Wilson and Co., of Leeds, produced an engine which was called 'Jenny Lind,' Plate 60. Of this class many scores were built; they had 15in. by 20in. cylinders, with 6ft. driving wheels. The drivers had inside bearings only, and the leading and trailing were 4ft. wheels, with outside bearings. They were largely used in the north, and as far south as Rugby on the Midland. These engines were principally designed by the late Mr. James Fenton."

Upon turning to Plate 60 a diagram of Jenny Lind is given, headed:—"By James Fenton, at E. B. Wilson and Co., Leeds."

If Mr. Joy had spoken at the time there would have been the advantage that Mr. Tomlinson would have been able to state his reasons for giving the credit to Mr. Fenton, whereas now, of course, his death has rendered it impossible for his reasons ever to be known.

Mr. Joy in his letter states that "Mr. Fenton came into the drawing-office and said we would try an inside cylinder, 15in. by 20in., with 6ft. cylinder driver." Those are the leading dimensions of the Jenny Lind, and were undoubtedly given by Mr. Fenton. Six-wheeled passenger engines were first constructed by R. Stephenson and Co. as early as 1834, the Patentee being the first built.



MIDLAND RAILWAY—ENGINE No. 60

Cranked axles with inside bearings only had been used by Hackworth in 1830, and by Bury in 1831; and the diagram given by Mr. Joy—Fig. 2—shows that the general design of the Jenny Lind follows very closely the engine of Mr. Gray; in fact, the whole of the evidence brought forward relating to the Jenny Lind question tends to confirm the opinion that during the past fifty years Mr. Gray has not received the full credit which should belong to him for the design of the engine built by Hackworth and Co. for the Brighton Railway.

In THE ENGINEER, page 25 of the present volume, reference was made to trials which took place upon the Midland Railway in May, 1848, between engines built by Wilson and those by Sharp Brothers and Co., of Manchester. As no drawing has been given of the latter engines, I enclose one for publication.

In 1847 the Midland Railway Company gave an order to Messrs. Sharp for six passenger engines, and they were delivered in April and May, 1848. They had no names, but were numbered 60 to 65 in the railway list. These engines had cylinders 16in. by 20in., and driving wheels 5ft. 6in. diameter. The two Sharp's engines, which took part at the trial in May, 1848, were Nos. 60 and 61, being Nos. 494 and 497 in the books of the makers. The six above-mentioned engines worked till 1870. It may not be generally known that in 1848-9 Messrs. Sharp constructed four broad or 7ft. gauge engines for the Midland Railway Company, to work between Gloucester and Bristol. They were Nos. 66 to 69, and had cylinders 16in. by 20in., and driving wheels 6ft. 6in.; having been ultimately changed to narrow gauge, these four engines continued at work till 1873-74. CLEMENT E. STRETTON.

Leicester, May 23rd.

PUFFING BILLY.

SIR,—With reference to the letter of Mr. G. S. Pardoe, page 518 "Locomotion" was built by Stephenson and Co. in 1825 for the Stockton and Darlington Railway, and is preserved at the Darlington Station. "Billy" was built in 1830 by the same firm, for the Killingworth Colliery line; it is now upon the High Level Bridge, but is about to be placed in Newcastle Station. "Puffing Billy" was built by Blackett and Hedley in 1813 for the Wylam line; it is at South Kensington Museum. Trevithick's engine of 1803 had smooth wheels and smooth rails.

Leicester, May 22nd. CLEMENT E. STRETTON.

SIR,—The celebrated original locomotive, "Puffing Billy," which is referred to in THE ENGINEER of May 22nd, page 518, is now preserved in the South Kensington Patent Museum. The locomotive that is upon the High Level Bridge at Newcastle, and now being removed into the Newcastle station for better protection, is "Billy," not "Puffing Billy," and was one of Stephenson's Killingworth engines, the first of which began running in 1815.

"Puffing Billy" was made by Hedley in 1813, for the Wylam Colliery line near Newcastle, and was the first practically successful engine with smooth driving wheels, and the father of the locomotive engine. It ran for fifty years on the line from Wylam Colliery to Lemington on the river Tyne, a few miles above Newcastle. W.

May 25th.

TRACTION ENGINES.

SIR,—Has anyone noticed the peculiar way in which the "Select Committee on Traction Engines" are working? They appear to have gone to the separate authorities and asked them if they are in favour of having someone above them to whom they could refer their imaginary grievances about traction engines. Of course with one accord they have said "No." I wonder if the Committee expected them to agree with it.

Why don't the Committee go to the traction engine makers and owners and see what is wanted, and give it to them—viz., higher speeds, and one licence of not more than £10 for the whole country, with the free use of any part of the day or night, instead of consulting these traction engine haters? Speed in towns and cities should not be less than four miles per hour, except in exceedingly busy places, and for the country it might be as fast as the engines can go with their loads.

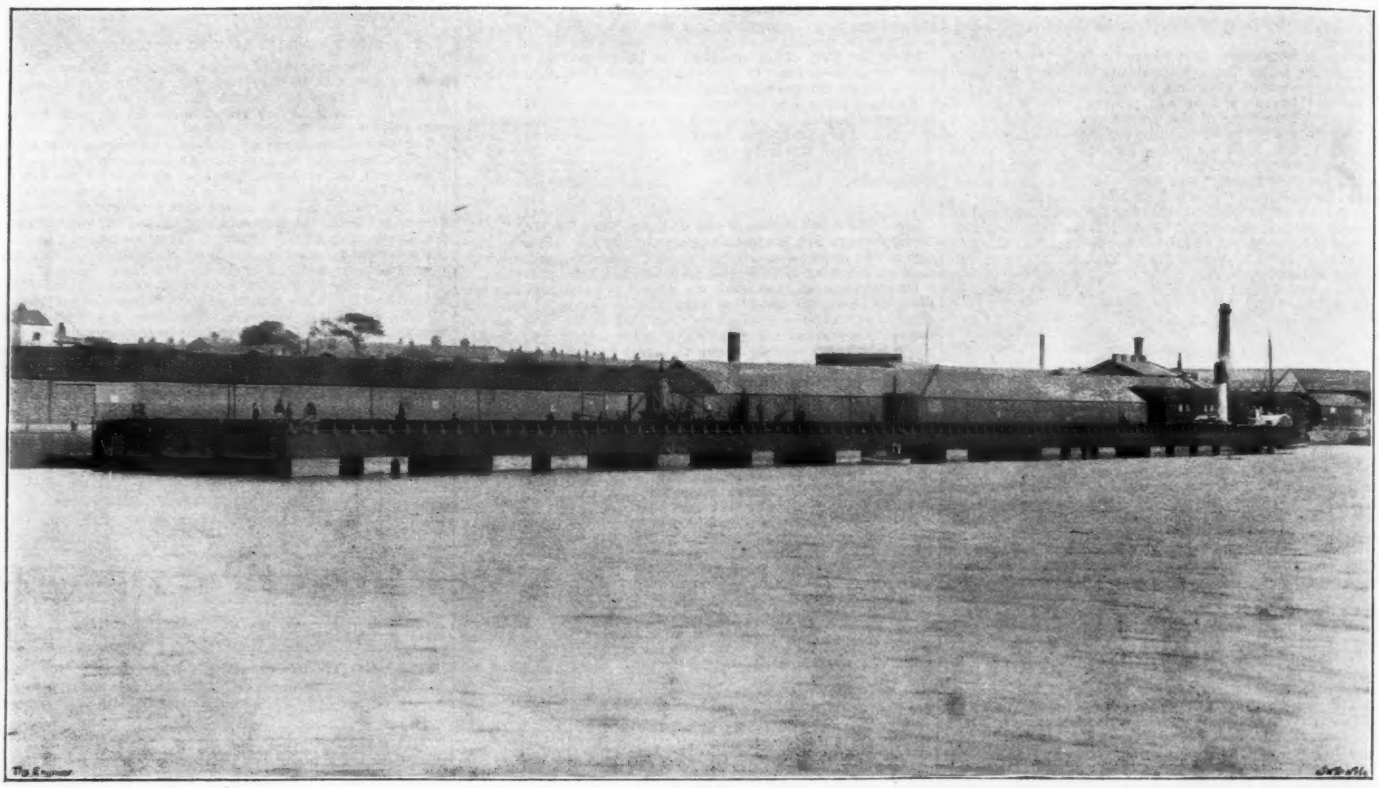
TRACTION ENGINE ADMIRER.

Smethwick, May 17th.

(*For continuation of Letters see page* 550.)

THE NEW LIVERPOOL LANDING STAGE

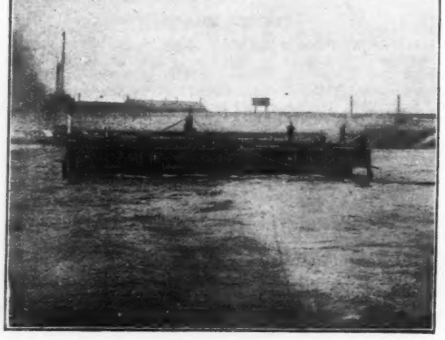
MR. A. G. LYSTER, M. INST. C.E., ENGINEER



LIVERPOOL LANDING-STAGE.

Liverpool has, as our readers are aware, been improving her position as a port, both as regards the reception of deep-draughted vessels and the convenience afforded to passengers. Following upon increased facilities, we find an increased traffic, and naturally, the demand for increased station accommodation. This must have been foreseen by the authorities of the Mersey Dock and Harbour Board, and the result has been that the landing-stage has been lengthened 400ft., that is, an addition of one-fourth to the already marvellous structure at which the passenger traffic of the port is conducted. This landing-stage has been the resort of visitors for many years; it is probably the largest and most frequented marine promenade in the world, and forms one of the principal features of Liverpool.

The first stage, opened to the public in 1847, was comparatively small, but with the growth of the cross-river and coasting traffic, additions were found necessary. In 1871 the Harbour Board obtained parliamentary powers, and in the course of three years constructed a landing-stage 2000ft. long. Unfortunately this was accidentally destroyed by fire shortly after it was opened for traffic; the damage, according to a local contemporary, amounted to £250,000. When replaced, the George's and Prince's stages became one.



THE STAGE IN MID STREAM.

The existing stage, with its recent addition, is 2460ft. long and 80ft. wide. It is floated on iron pontoons 80ft. long by 10ft. wide, spaced 15ft. from centre to centre. On these are riveted five box girders 4ft. 4in. deep by 3ft. wide, evenly divided between the centre and ends of the pontoons. The box girders are surmounted by cross girders to carry the flooring; they are hog-backed plate girders 26in. deep at the centre and 14in. at the ends, and are spaced 4ft. from centre to centre. Upon these 4in. creosoted timber is laid, and a second layer of 4in. greenheart planking, surmounted by a layer of asphalte, completes the flooring. The completed stage will be approached from the shore by eight wrought iron bridges; one end rests on the quay wall, the other end on the landing-stage, and these provide access to the stage. The stage rises and falls with the tide, the extreme range being 30ft. There is also a floating bridge 550ft. long and 35ft. wide, which enables heavily laden vehicles to be dealt with, affording an easy incline at all times of the tide.

The new length of 400ft. was constructed by Messrs. Pearson and Knowles, the iron being rolled and prepared at their works, Dallam Forge, near Warrington, and put together in the Wallasey Dock near Birkenhead, on pontoons supplied by the Phœnix Co., of Derby, to the design of Mr. A. G. Lyster, Engineer to the Mersey Dock and Harbour Board. Nineteen pontoons were in place at the beginning of this month; by this time the ironwork of the superstructure was completed, and it was determined to remove the stage from Birkenhead to Liverpool. The illustration shows the stage in dock, ready for removal, with steam tugs attached. As will be seen, it is an unwieldy structure. It weighs 1475 tons, and is not calculated to steer well, as the pontoons lay athwart the centre line; the responsibility of floating it across the Mersey to Liverpool was, therefore, very great. This, we were glad to see, was most successfully accomplished on the 3rd inst. The day suited admirably for the operation—a low neap tide was ebbing comparatively slowly, and a light northerly breeze produced scarcely a ripple on the surface. Under less fortunate conditions the work of the contractors would have been very different. Four steam tugs were employed, two in line ahead to drag the stage, and one on each corner aft to steer it. In little over half an hour from the time of starting at Birkenhead the stage was alongside the quay at Liverpool. The Teutonic lay in the track from the Alfred Dock to the north end of the existing stage; the tow was dropped deftly under her stern and brought across without a hitch. It was then necessary to place it in position, and to join the plates of the old and new work together. The measurements, both as to width, depth, and floating level of the stage—the accuracy of every item being essential to success—were so perfect, that the top and bottom plates and angle irons of the box girders were fitted at once, and temporary bolts and drifts were passed through holes, one-half of which were in new and the other half in old work. The start was made about two hours before low water, and it was necessary that the junction should be effected before the turn of the tide, for even at neap tides the run in the narrows at Liverpool is somewhere about three miles an hour. The stage was secured by timber moorings, until the permanent mooring chains could be got into position, and by a ponderous iron boom from the quay wall.

RIVER MERSEY

GENERAL PLAN

The stage now extends from the centre of George's to the north end of Prince's Dock. From the entrance of the latter a timber jetty 250ft. long has been projected in the direction of the landing stage, and a bridge, 152ft. long and 14ft. wide, will open communication between the two. This jetty has an upper and a lower deck, and is also provided with inclines to facilitate communication.

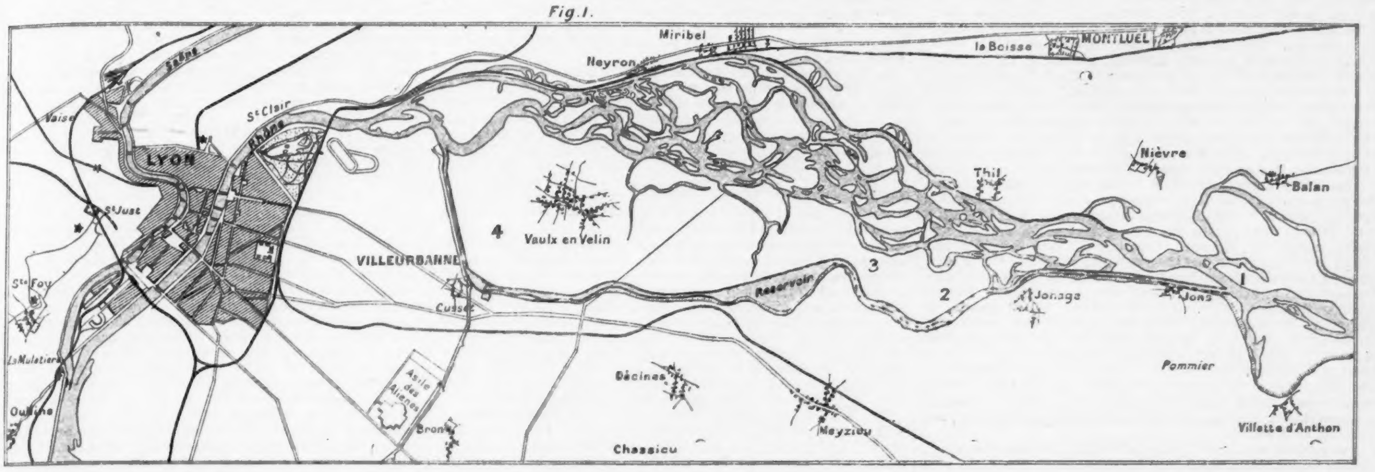
The traffic carried on at the Liverpool landing-stage is of considerable interest. Until recently it was confined to a comparatively small class of steamers, and not long since the water at the south end was so shallowed by the advance of Pluckington Bank in that direction that the ferry steamers were obliged to change their berths at low water. This alarmed the authorities and inconvenienced the public, and led to the construction of a system of sluices in the quay wall, through which the water in the dock was discharged at low water. This, assisted by dredging, maintained a sufficient depth of water for the ferry boats alongside the stage. No less than nine ferries are accommodated at this stage, and many of them run four times an hour.

On the August Bank Holiday last year, 263,000 persons passed through the turnstiles and used the landing-stage. Until recently only small craft, such as ply between Liverpool and the Isle of Man, Ireland, and Scotland, came alongside. The traffic by these boats, however, is considerable, and amounts at times to forty to fifty a day, as many as thirteen steamers occasionally going to and coming from the Isle of Man in a single day.

The Dock Board, having improved the access by dredging the bar, then turned their attention to dredging in the river, The depth alongside the stage may be taken as 11ft. at the commencement of 1895, when dredging commenced, some of the older dredgers being employed. During last summer the sand pump dredger Brancker was also sent there, and up to the beginning of this month 1,200,000 tons had been removed. There is now 30ft. alongside the stage at low-water spring tides. The Lucania inward bound, drawing 26ft. 6in., has

INLAND NAVIGATION IN FRANCE—THE JONAGE CANAL

Fig. 1.



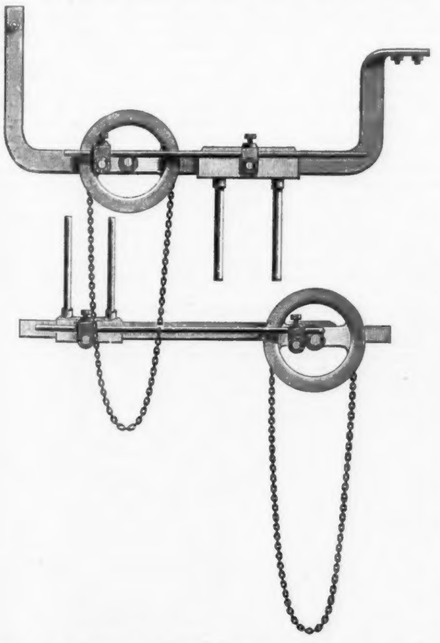
berthed at the landing-stage at dead low water, and liners, loaded to their maximum draught of 29ft. 6in., have left it. The Germanic, White Star, and Cephalonia Cunarder were the first American liners to use the stage on June 12th of last year. During eleven months 250 vessels of this description have been accommodated at the stage. It is therefore evident that the extension has not been made a day before it was wanted.

We must consider the riverside railway station opened last summer as being largely responsible for the extension of the landing-stage. This station was rapidly built. The roof, which is 800ft. long and 87ft. 6in. wide, contains 400 tons of iron. The iron was rolled and erected by Messrs. Pearson and Knowles in three months. The expedition with which the work was carried out was mainly due to the simplicity of the design. By arrangement the requirements of the engineer were limited to sections easily rolled and easily worked. Forgings were avoided—practically the roof consists of flat bars and angle irons connected by gusset plates.

At present the London and North-Western Railway are the sole users of the station, but provision has been made for the Midland Railway and its allies. From this station the journey to and from Euston by special train *viâ* Edghill is made in a little over four hours. The Atlantic liners lie at the landing stage within a stone's throw of the railway carriage, quick despatch is secured, and the discomfort inseparable from the use of tenders between a big ship and the shore is avoided.

SIMPLEX DEAD-LOCK BELT SHIFTER.

THE accompanying engraving illustrates a simple and very ingenious belt shifter, brought out by Mr. E. S. Ratcliffe, of the Ceres Ironworks, Kingston. The engraving shows it in two forms. As will be seen, it consists of an iron bar which is bolted to the underside of the beams carrying the shafting. On this slides a small casting carrying two forks through which the belt to be shifted runs. To this casting is attached, by means of a stud, a rod which serves as connecting rod, which at its outer end is attached to a crank on a small cast iron chain pulley. The weight of the rod and the big end of stud are sufficient to keep the belt in either position, either on the fast or loose pulley as may be desired. To shift it all that is necessary is to pull at the chain until the crank passes the top centre, when it will fall through of its own accord and remain there. These belt shifters are produced at a very moderate price, and will be very useful in the turnery and machine shops.



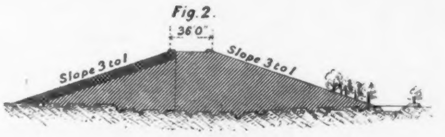
A TELEGRAPHIC message was dispatched from the Electrical Exhibition now being held at New York, and, after making a double circuit of the globe, it returned to its starting-place, the time occupied being 50 minutes. *The Electrician* says, President Chandler, of the Postal Telegraph Department, sent off the message, and Mr. Edison, sitting at the same table, received it.

THE JONAGE CANAL.

IN our impression of June 7th of last year we described and illustrated some of the principal works of engineering construction belonging to this important undertaking, which is intimately connected with the inland navigation of France. Since that period the execution of the whole project has made very considerable progress, and some further particulars are newly to hand which may not be uninteresting to our readers, and will bring the whole subject well up to date. It cannot be truthfully said that our neighbours have ignored the many advantages which accrue to a country from an extensive development of its inland water communication, for witness the scheme for making Paris a seaport, also that of the Canal des deux Mers, and not to mention others, the great enterprise of bringing to the walls of the capital the waters of Lake Leman. But none of these vast projects has as yet exchanged the ideal for the real, while in other parts of the world, in striking contrast, are the recent utilisation of the Falls of Niagara, the Corinth Canal, the new water route which has unquestionably converted Manchester into a *port de mer;* the Baltic and North Sea Canal, and the great hydraulic engineering works undertaken for improving the navigation of the Iron Gates of the Danube.

It will be seen on reference to the accompanying plan—for which we are indebted to our contemporary, *La Revue Technique*—in Fig. 1, that the canal commences at the point 1, in the vicinity of the town of Jons. Here the river Rhône makes a very perceptible bend, which, combined with the strength of the current, causes it to dredge out its own channel along its left bank. The consequence of this automatic scouring action is that the bed of the canal will always be a good deal higher than that of the river, and consequently be in no danger of silting up—an evil to which all works of this description are liable, and from which very few are exempt. At the point 2 in the plan, where is situated the dam with the twenty-two sluice gates, forming one of the works referred to at the commencement of our article, this first part of the canal, which is in direct communication with the Rhône, and may be termed the supply section of it, terminates. The second portion of the canal extends to Cusset-Villeurbranne, where the hydraulic works and the double-chambered lock are situated. After passing point 3, the canal skirts a large tract of marshy ground, forming a naturally impermeable reservoir, which can be utilised as a regulator for the level of the water of the canal, and would, by a skilful system of impounding, raise the power available from 12,000 to 20,000-horse power. In a total length of ten miles, there are six miles of straight reaches, and eighteen curves of radii varying from 330ft. to 6600ft. Besides serving as the creator of hydraulic power of great magnitude, the Jonage Canal will be essentially a canal of navigation, and will, moreover, enjoy the somewhat exceptional privilege of being entirely free and open to the public, without payment of dues, taxes, rates, charges or imposts of any description whatever. Its normal width will be 200ft., with a depth at low water of 8½ft. For a length of about five miles from its take-off, the canal is in cutting, and elsewhere partly in cutting and partly in embankment, with slopes in both instances of not less than two to one. Wherever necessary, puddle has been used to render the sides and channel watertight. This precaution was not necessary in the construction of the outlet canal, which has a length of two miles before it ultimately falls into the Rhône, since it is altogether in cutting. As the force of the current is exceedingly feeble, the inclination of the bed being uniformly about 1in. in every dozen miles, no fear need be entertained respecting the wear and tear of the banks, and so the Société des Forces Motrices du Rhône has been spared the expense of protecting walls of masonry.

Fig. 2.



Although the level of the canal can always be regulated by the sluices erected at the take-off, the additional precaution has been adopted of constructing, near the point 3 in the plan, a bywash which will allow any sudden and accidental rush or flood of water to find its way into the river, without occasioning an undue rise at the hydraulic and electric installations. In reality, an overflow in the strict sense of the term, and in constant and uniform operation, was not required here, but simply a trench or cut, from 300ft. to 600ft. in length, made in the embankment at the level of high water in the canal. At about two miles further up the canal, in the direction of Lyons, a compensating reservoir has been built which deserves a word of notice. Its volume or capacity is 54,000,000 cubic feet, and owing to the favourable character of the contours of the ground, its cost was restricted to the price of the acquisition of the necessary area and of the accompanying sluice gates, which are of a simple and comparatively economical construction, since they are subjected to a head of water not much exceeding 3ft. The advantage of this compensating reservoir is thus very considerable for the hydraulic department of the whole undertaking. The object of the sluice gates is, in cases of necessity, to enable the reservoir to be closed—that is, cut off completely from the canal—and also to maintain the water level of the canal at a uniform height. It is evident, therefore, that if the consumption of water by the turbines should lower the water level of the canal, the deficiency would at once be made good by a fresh supply coming in from the compensating reservoir. If, again, on the other hand, the supply to the turbines should be more than they required—a condition obtaining during the night time—the surplus water would be diverted to maintain the water level of the compensating reservoir. The conclusion to be drawn from this *va-et-vient* arrangement is that the compensating reservoir will impound the surplus water not required by the turbines at certain times, and restore it again to them when they require it, by maintaining the water level of the canal at a constant height, whatever may be the demand for supply drawn upon it by the working of the turbines.

A section of the canal in embankment is shown in Fig. 2, from which it appears that the old puddle wall type of construction is abandoned, and the puddling transferred to the inner or waterside of the bank, as indicated by the dark shading on one of the slopes. The general dimensions of the bank are as follows:—Height, 30ft.; width at top, 36ft.; and as the slopes are 3 to 1 on each side of the bank, the width at base becomes equal to 250ft., which ought to be ample for the comparatively small height. This embankment, which forms the right bank of the whole length of the supply canal, was made up partly from the excavated material of the canal itself, and partly from that from the outlet canal, which, as already stated, is wholly in cutting. It is confidently expected, and the present progress of the works certainly seems to warrant the anticipation, that the whole undertaking will be completed before the end of next year.

"INVENTION"—THE INDEFINABLE REQUIREMENT OF THE PATENT LAW.

THE subject of a patent must be not only new and useful, but must also be an invention. The courts hold that an improvement is not patentable, if there is no invention. With regard to the first two requirements but little difficulty has been experienced, or is to be anticipated; they relate to matters of fact and evidence. Questions involving them would be decided on the ordinary rules which apply to such matters. A thing must be considered new if no similar co-ordination of mechanical or other elements is on record. So, too, if it does not appear that a device is hurtful, it may for the purposes of the patent law be considered useful. Contrivances which are absolutely negative and inert are sufficiently rare to be left out of consideration; besides, a more positive or active interpretation of this word must presuppose not only a universal range of information, but prophetic insight on the part of those whose duty it is to determine the issue. Further, the patenting of such devices, did they exist, could work no more serious injury than the encumbering of the records. With regard to the third requirement, a very different state of things presents itself.

It is my intention to show that though the third requirement has always been in the statute, and its meaning substantially the same as the present interpretation, until recently it has practically been a dead letter. Further, that it is not by any means axiomatic that the third requirement is in any case possible of fulfilment, but, on the contrary, there are many cogent reasons for questioning whether "invention," like "spontaneous generation," is not a metaphysical myth. That, even if it be in fact a real quality, it has never been defined, nor is it of such a character that its presence can in any case be determined beyond doubt. All authorities agree that "questions of invention proceed upon fine and subtle metaphysical distinctions." Strangest of all, the law and practice relating to patents, which provides this requirement involving metaphysical distinctions, also provides that decisions relative to these philosophical subtleties shall be rendered by mechanics, chemists, lawyers, &c., but never by expert metaphysicians. That in effect the Patent-office examiners and judges decide these questions arbitrarily. So the third requirement works injustice in all cases, but particularly in those involving the results of the highest and best form of mental industry, which the patent law was particularly designed to foster. And that it should be removed from the statute, and the idea eliminated from the practice both in the Patent-office and courts.

The phrases descriptive of invention used by the courts are very few, viz.: "Inventive genius," "the genius of an inventor," "the inventive faculty," "invention as distinguished from mechanical skill," "invention as distinguished from construction," "ingenuity as contrasted with the judgment of a skilled workman." These, of course, are not definitions, but simply phrases supposed to be descriptive. Though the term "invention" has never been defined, legally or otherwise, either as a mental process or product, attempts to describe it have not been lacking. The following will, I think, suffice to show the inextricable confusion and difficulty arising from these attempts. I quote from Merwin's "Patentability of Inventions," a good authority, though on this point one is as good as another, each being simply a summary of legal decisions :—"An idea is not an invention if it be in the nature of an inference. It is true, of course, that what is plain inference to one man is a sealed book to another. But the inference here spoken of is that which is natural to a man of ordinary intellect, possessing the ordinary skill and knowledge of the art in respect to the inference drawn." This is under the head of "Test of Invention," page 18. Would not such a test simply shift the inquiry from the invention to the inventor? Then, too, the most striking characteristic of men's minds is the vast difference between them in this very matter of drawing inferences. This it is which makes the difference between the thousand a year and the thousand a month man. Again (page 22), "Invention is imagination, it is the very opposite of reason or inference. . . . . It is not a sort of elevated reason, it is a faculty, which differs in kind from reason, which often in truth is free to act only when reason has been thrust aside, and its conclusions ignored, nay, denied." Certainly this is to the point, and ought to serve as a guide, but later we come upon this ". . . . In the last analysis reasoning and imagination are both perception of likeness, and reasoning shades off into imagination." Here is another suggestion :—". . . . When the mind invents, it starts with the conclusion. The conclusion flashes, so to say, upon the mind . . . . an instance is the case of the barbed wire fence." This does not appeal to the mind as axiomatic or even beyond question, nor does the illustration necessarily fit the stated conditions. Is it not much more easy to think of the "barbed wire" as the result of inference from direct or reminiscent observation, than as a conclusion flashed upon the mind, out of nothing, as it were?

Let us suppose a case :—A man is walking through the woods searching for his cattle which have broken through the plain wire fence of their paddock. Suddenly he is brought forcibly, painfully, to a halt by an aggressive blackberry bramble which has grown across the path and attached itself to a tree. Is it, I ask, necessary to endow that man's mind with an "inventive faculty," "inventive genius," with, in fact, anything other than ordinary reason, that he should be enabled to draw the inference from his own experience with the bramble. That, were it as strong as his plain wire, it would be more efficient as a fence; or in other form, had his wire been armed as the bramble, his cows would not have pushed against it.

These quotations illustrate how vague and misty are the criteria of "invention," and Mr. Merwin says in his preface, "His aim has been to make the book essentially practical." And this, undoubtedly, he has done, so far as the subject would permit. Judge Shepley says: "No more difficult task is imposed upon the court in patent cases than that of determining what constitutes invention, and of drawing the line of distinction between the work of the inventor and constructor." A careful reading of the decisions involving invention, the summaries of Robinson, Merwin, and others, show that to distinguish between so-called "invention" and the results of other normal mental practices which, according to these same authorities, are "foreign to invention," if not absolutely impossible, is a task of the most abstruse, subtle, and difficult character.

After forty-five pages of such an attempt, Mr. Merwin says, under the head of "Conclusion":—"We are far from thinking that our suggestions are equal to the difficulty of the subject, neither do we fancy that the most thorough and correct analysis would render it easy henceforth to decide upon the presence or absence of it—invention—in any given case." This is but repeating in other words the remarks of Justice Brown, in the Supreme Court, in McClain *v.* Ortmeyer, 141 U. S. 419, who, after speaking of the impossibility of defining invention, calls it "that impalpable something which distinguishes invention frome simple mechanical skill."

Up to comparatively recent times the workers in the field of mechanical improvement were few, and the results scattering and disconnected, but withal great and surprising. It is not, therefore, to be wondered at that to those not directly connected with the day-by-day preparation these results should appear as the work of persons differently endowed to themselves, to whom both process and result alike appeared mysterious. It is the normal action of the human mind to ascribe to occult sources results beyond its present comprehension. Owing to the comparative fewness and lack of connection between patentable devices at the time referred to, novelty frequently, if accompanied by complication of parts, was considered sufficient evidence of invention, so that, practically speaking, though on the statute books, the present idea of invention as a vital principle in patentability has been a dead letter.

The history of invention and the current decisions make the conclusion almost inevitable that, though theoretically a suppositious "something" other than novelty and utility was and is required, the practical working and effect has always been that apparent novelty in a high degree served to prove the presence of "invention," and a low degree of novelty to show its absence. This course is pursued deliberately by some judges. Merwin says, page 17:—"Certain judges do not even ask if a new function or effect has been produced. They assert that the statute requires only that the thing to be patented shall be new and useful." This apparently rough-and-ready, though really scientific, method, whether employed deliberately or not, served excellently, and carried out the undoubted intention of the patent statute, viz., to reward the producers of devices of a high degree of novelty and utility, the result of unusual intelligence or industry. Open and continued practice on the same lines would doubtless continue to prove equally effective in carrying out the spirit of the statute.

In recent years the scope and ramification of mechanical and other industrial processes have become world-wide, affecting every act of life. Consequently the points of contact and coincidence of new devices have become more numerous, and opportunities for striking novelties have become fewer and fewer. It is under these circumstances that this subtle metaphysical—one is tempted to say occult—idea of invention has been given prominence, and the patentability of devices determined by fallible personal opinions, instead of facts and evidence. The legal text-book writers, with every intention of rendering assistance to work-a-day men on a subject of practical importance, in dealing with the accepted idea of invention are irresistibly forced in the mazes of metaphysical and philosophical abstrucities. But admitting what the text-book writers and the courts say on this subject, that invention does exist, though indefinable; that it is an "impalpable something" wholly within the domain of metaphysics and philosophy, does it not seem utterly illogical that the determination of these subtleties should be left to mechanics, chemists, and lawyers. Would it not be more reasonable that the examiners in the Patent-office, instead of being versed in the arts of their departments, be metaphysicians trained to determine mental principles and operations. And above all, would it not be more logical to try patent cases involving these issues before this same kind of experts, than as at present before judges who are neither specialists in the art involved nor metaphysicians, but simply men trained to determine and discriminate in matters of fact. "The mental process of invention, in most cases, is very similar to that of discovery. . . . . . The distinction between them is almost always overlooked, sometimes its existence is denied by the courts."—Merwin.

There is, as has been hinted at, still another phase of this question, namely, that "invention," instead of being the result of a peculiar, unique, and altogether exceptional mental process, is simply the result of conscious or unconscious reasoning on data supplied by observation, and in all respects similar to other mental processes in which observation, memory, and reason take part. This view was set forth at some length in a recent number of the *Engineering Magazine*, under the title, "Is the Inventive Faculty a Myth?" by the present writer. It is not necessary to the present argument, and is simply referred to as offering a possible reason for the difficulty of defining wherein invention differs from other rational processes, also as suggesting the justice and advisability of determining, first, the existence of "invention," as interpreted by the courts, beyond question. Before demanding its presence as a statutory requirement to a common contract. "The statute demands a peculiar process of mind as the characteristic of invention. . . . The statute is so interpreted by the courts. . . . It is impossible to arrive at the patentability of an improvement in any other way."—Merwin.

As illustrating how this demand for the presence of "invention" works in practice, take this case:—The Patent-office refuses to grant a patent, not on account of lack of novelty, for no anticipating device can be found; it is admittedly of great practical importance, but it is refused simply on the ground of want of invention. After exhausting argument, the applicant finally says: "Surely we must be quibbling about words. What does the office mean by 'invention?' What has the examiner in mind which he says this device lacks?" To this there is no reply except the arbitrary exercise of power. This is not a supposititious case, for of late years it is becoming of frequent occurrence.

Before drawing conclusions from all the foregoing, I desire to make some remarks, which, while they do not bear directly on the present argument, do bear on the subject of invention in general, and will probably serve to give point even to the present matter. The courts and authorities are agreed that "invention involves the spontaneous conception of some idea not previously present to the mind of the inventor" (Robinson), but that wise judgment in selecting and combining ideas already there has no part therein, and that "reasoning is not invention."—Merwin. It is justly inferable, therefore, that inventive ideas do not depend upon other ideas, or they would not be spontaneous, but simply inferences.

This being so, it logically follows that a mind devoid of ideas, if such were conceivable, would be as fertile a field for invention as one rich and full of ideas, concepts, and observations. Or, to put it in another form, that in a mind stored wholly with, say, legal concepts and ideas, a mechanical invention is as logically probable as in a mind filled with observations of every variety of mechanical elements and combinations. The born blind should invent new colours, and the born deaf compose music.

At the risk of opening the door to a metaphysical argument, which I would avoid, being a mechanic and not a philosopher, and my present object being the wholly practical one of suggesting a way of taking patents out of the misty region of metaphysics into the domain of facts, where they belong, still, I cannot refrain from suggesting that when the first sentient atom perceived inert matter, the concept of resistance originated, the first embryonic idea, with and from which all others have risen in continuous and unbroken sequence.

In every attempt to disentangle "invention" from other forms of thought much stress is laid upon the idea of its instantaneousness of operation. This, I take it, is a relic of ignorance, for we now know that even thought is not instantaneous. Rapidity is characteristic of all thought. Is it not possible that behind this question of time lurks hidden the solution of many of the difficulties of "invention" as interpreted by the courts? The phonograph is frequently cited as one of the most perfect illustrations of inventive genius. In this I fully concur, and, further, I hold it to be an equally beautiful example of pure inductive reasoning, and that the idea of the phonograph being "spontaneously conceived" is simply unthinkable. For its conception a distinguished line of ancestry was required, among which, as near kinsfolk, were very sturdy ideas of sound waves, elasticity of diaphragms, and whole troops of mechanical ideas. And for a birthplace a mind furnished with every achievement of modern science and lighted by logic as clear as noonday. Spontaneously conceived, forsooth!

In contrast to this may be mentioned the illogical unreasoning and unmechanical attempts of Von Kempelen, and later of Faber, to make a talking machine by copying the human speech organs, ignorantly overlooking what simple observation should have taught, that the human mouth, with other functions, is a tasting device, a grinding apparatus, and a fighting machine, and only last and least of all, and incidentally, is used for talking; for which purpose, by the way, it is so ill-adapted that it takes years of adjustment to do in the way of talking what the phonograph does instantly it is made. "Reason is unravelling and invention is weaving of thought. Reason is analytic, invention is synthetic."—Merwin. The error of this lies in the fact that reason is both analytic and synthetic. Illustrations, both analytic and synthetic, of convincing character could readily be given, but they would be out of place in this article. In the class under consideration—viz., inventions in which reasoning appears to be solely employed—reasoning is, indeed, the faculty most conspicuously used; but imagination must be employed before the reasoning begins, and in order that it may begin. For in these cases invention—imagination—is exercised. . . in selecting out of a great many possible elements, the particular element to accomplish the result desired."—Merwin.

A pertinent inquiry is here suggested: "Invention"—imagination—being unreasoning, how is it possible for it to select? The quotation in effect concedes my whole contention. The courts and text-book writers first eliminate reason, and then immediately proceed to endow imagination with a power of intelligent selection, which is reason.

The better idea of imagination—I avoid the word "invention" as being misleading—is just what the word implies, mentally seeing images, that is, a sort of mental pictorial scrap book, in which is stored past visual observations—leaving out of consideration those who derive their principal impressions through other senses. The imagination is just as inert and as incapable of conception, spontaneous or otherwise, as the physical scrap book used as illustration. The circumstances of life and man's contact with nature disclose wants, deficiencies, and lack of adjustment between him and his environment, which reason sometimes supplies by selecting directly from physical nature or by recourse to the scrap book of reminiscent observations, *i.e.*, imagination, image memory, *alias* visual memory, *alias* visualisation, *alias*—though wrongly—invention. A patentable combination, no matter how involved or complicated, is simply an aggregation of co-ordinating individual wants or deficiencies which have been individually supplied.

It would be an entirely erroneous impression to derive from my remarks, that because I question the existence of "Invention" as interpreted by the courts, I also discredit "Genius" or believe that poets are made, not born. I hold in the profoundest reverence those giants of intellect, both past and present, to whom the world owes its masterpieces, and I do not fear that an intelligent inquiry into the causes of their greatness, no matter how searching, will detract from their glory or tend to diminish their number in the future.

It may possibly be urged by some, that tribunals of law when they adjudge the existence of the "inventive faculty" simply adjudge the existence in certain individuals of capabilities, which enable those so gifted to accomplish results superior to anything which might reasonably be expected from the best minds and skill at present engaged in the cognate arts or callings; and when the same tribunals adjudge that a certain thing is an invention, they simply adjudge that it is distinctly superior to and different from anything that might reasonably be expected from the skill of the best minds versed in the arts involved.

If what has gone before is not considered to meet this objection, then a complete answer is to be found in the decisions of the United States Supreme Court, in which it has been held time after time that simple superiority, or superiority accompanied by novelty, either in device or result, does not entitle it to be considered an invention, or entitled to the benefit of the patent statute. On this point I refer to the following cases taken at random:—Union Edge Setter Co. *v.* Keith, 139 U.S. 530. It was decided that the claim lacked invention, though the result was a more perfect machine. Bussel Trimming Co. *v.* Stevens, 137 U.S. 423. Patent performed the work it was designed to accomplish in a better and more workmanlike manner, and yet was held to lack invention as being improvement only in degree. Consolidated Roller Mill Co. *v.* Walker, 138 U.S. 124. Conceded that the peculiar arrangement of patentee is attended with better results than previously, still this would not necessarily sustain patent. Aaron *v.* Manhattan Railway Co., 132 U.S. 84. Though patentee was entitled to the merit of being the first to conceive the convenience and utility of a gate opening and closing mechanism which could be operated efficiently by an attendant in a new situation, still this merit might not sanction patent. Though taken at random, these serve to show that superiority is not a criterion of invention, nor is novelty, nor yet superiority and novelty, though they may indicate it; but the statute as interpreted by the courts demands something else, which is not simply superiority nor novelty, nor even a combination of these qualities.

It may, of course, be said that the devices in question did not disclose the degree of these qualities contemplated by the statute, but this simply carries the question back again to the original difficulty not a whit simplified. The determination of that degree would still be left to the arbitrary decision of individual opinion. But this line of argument is futile anyway, for it is not in accordance with the facts of the case. The statute as interpreted does demand a prescribed character of mental operation or evidence of it in the device as a condition on the part of the produce to entitle him to the provisions of the statute.

It is urged that the law being practical simply attaches to words it employs—the meaning as nearly as possible given to them by common consent—and does not inquire if the words correctly interpret facts, or whether there is any real foundation for them in fact. It simply uses them as the best means available to convey a meaning. Even this does not help the matter if that meaning be erroneous or confusing and a source of continued and increasing trouble, tending to thwart the very end for which the statute was formed. That this is the case with the words invention, inventor, and invented, is thoroughly appreciated by both the producers of new devices and lawyers whose business brings them into close acquaintance with matters relating to patents and patent litigation. And it is with this practical difficulty that the writer as a mechanic is interested at this time, and not with any fine-drawn metaphysical distinctions or modes of mental action. It does not follow, of course, that because the present interpretation of a word in the statute works confusion and difficulty, that therefore the statute is based upon a wrong idea, and ought to be abolished. This paper has gone far wide of its intention if such an idea is deducible therefrom.

The patent statute stands a monument of human wisdom which has few rivals either in honesty of purpose or grandeur of result, and the writer would be the last to suggest anything which in his judgment would tend to weaken or cripple its beneficent working. The very opposite of this is the intention, which is simply to suggest the elimination of those elements which tend to obscure the meaning and balk the evident purport of the statute.

The object of the patent law was undoubtedly to encourage and reward industry and intelligence when directed in channels beneficial to the commonweal. There certainly was no idea of rewarding certain supposed freaks of nature for the possession of a peculiarity they could not help. Therefore, putting aside any metaphysical controversy, inasmuch as the criteria of one of the requirements to the patent contract are so utterly indefinite and the determination so impossible, does it seem the part of the practical common sense and business-like procedure to eliminate the element of confusion? All other matters which have been found by practice to be good and desirable would remain unaffected.

In fact, the substitution of the idea conveyed by such words as discovered, produced, thought out, reasoned out, for that which now attaches to the third requirement of the patent contract, would work no change whatever in the spirit of the statute to reward intelligent industry, but would sweep away the cobwebs of mysticism which festoon the ideas supposed to underlie the word "Invention."—*W. H. Smyth in the Mining and Scientific Press (San Francisco).*

THE FEDERATED INSTITUTION OF MINING ENGINEERS.

A GENERAL meeting of the members of the Federated Institution of Mining Engineers will be held in London on Thursday, June 4th, at 12 noon, and on Friday, June 5th, at 12 noon, in the rooms of the Institution of Civil Engineers, 25, Great George-street, Westminster, London, S.W.

Arrangements have been made for visits to the works of the Electric Welding Company, the Deptford Station of the London Electric Supply Corporation, on Friday, June 5th; and to the works of the Waterloo and City Railway Company, on Saturday, June 6th, 1896. The following programme has been issued:—

Thursday, June 4th: 12 noon.—General meeting in the rooms of the Institution of Civil Engineers, 25, Great George-street, Westminster, London, S.W. An adjournment will be made for luncheon from 1.30 to 2.30 p.m. The following papers will be read, or taken as read:—"Presidential Address," by Mr. Geo. A. Mitchell; "The Causes of Death in Colliery Explosions," by Dr. J. S. Haldane; "Road Engines," by Mr. John McLaren; "The Gobert Freezing Process of Shaft-sinking," by Mr. A. Gobert; "Precautions necessary in the Use of Electricity in Coal-mines," by Mr. H. W. Ravenshaw. The following papers will be open for discussion:—"Photography in the Technology of Explosives," by Mr. Alfred Siersch; ("Trans.," vol. xi., page 2. "Coal-washing Plant at the Wirral Colliery, Neston, Cheshire, by Mr. J. Platt; "Trans.," vol. xi., page 55;) "Lead and Lap of Winding, and other Engines;" by Mr. Hargrave Walters; ("Trans.," vol. xi., page 64.;) 4.0 p.m.—General Meeting will be closed.

Friday, June 5th.—Excursion No. 1:—9.30 a.m.—Visit the works of the Electric Welding Company, 21, Hindon-street, Pimlico, S.W., and inspect the Thompson electric welding process. The visitors will be received by Mr. R. J. Wallis-Jones. Take train or omnibus to the Victoria Station, and walk to the works, which are closely adjacent. 12 noon.—General meeting in the rooms of the Institution of Civil Engineers, 25, Great George-street, Westminster, London, S.W. The following papers will be read, or taken as read:—"Powdered Coal Firing," by Mr. Bryan Donkin; "The Southern Limit of the Nottinghamshire Coalfield," by Mr. G. E. Coke; "The Indian Goldfields," by Mr. A. G. Charleton; "The Witwatersrand Goldfields," by Professor L. de Launay; "Mechanical Roasting of Ores," by Mr. Horace F. Brown; "Lake Superior Mining Ore Region, with Special Reference to the Masabi Range," by Mr. Horace V. Winchell. The following papers will be open for discussion:—"The Eastern Limits of the Midland Coalfield," by Professor Ed. Hull, F.R.S. ("Trans.," vol. xi., page 9); "The Goldfields of Matabeleland," by Mr. F. G. Shaw ("Trans.," vol. xi., page 29); "Electric Welding," by Mr. T. Scott-Anderson ("Trans.," vol. xi., page 40). The Müller smoke and gas mask will be exhibited. 4 p.m.—General meeting will be closed. Excursion No. 2:—4.30 p.m.—Visit the Deptford Station of the London Electric Supply Corporation.

Saturday, June 6th.—Excursion No. 3:—9.30 a.m.—Members may visit the works of the Waterloo and City Railway, and are desired to assemble at the shaft sunk in the river Thames, near Blackfriars Bridge. The party will be received by Mr. Dalrymple-Hay, resident engineer; Messrs. Wales and McDonnell, assistants; Mr. Wm. Rowell, contractors' agent; and Mr. Chas. Campbell, contractors' engineer.

TRADE AND BUSINESS ANNOUNCEMENTS.—Mr. James S. Gaskell, M.I.C.E., has been appointed resident engineer to the Surrey Commercial Dock Company, in succession to the late Mr. James Adair McConnochie.—The Hamburger Metall-Walzwerk von George Dittmann and Co., have appointed Messrs. Weager and Funck, 1, Whittington-avenue, London, E.C., sole agents for the United Kingdom for the sale of their yellow metal and copper sheets and sheathing, and other manufactures.

RAILWAY MATTERS.

The Light Railways Bill is down for Monday next, and the occasion will be seized for obtaining promises concerning the passenger duty and carriage tax.

In connection with the Royal Agricultural Society's show at Leicester, the Midland Railway Company is making arrangements for visitors to take tickets to and from Derby, and accommodation at the company's hotel at Derby, for the several days of the Show week.

Travellers on the Great Western Railway propose to present a testimonial to Benjamin Jeans, the oldest guard on the line, who will retire from the company's service at the end of the present month, after fifty-three years' work. A fund is being raised for this purpose.

Through trains over the Brooklyn Bridge are again proposed by the Brooklyn elevated railways. They propose to have the engines fitted with cable grips. The weight of a train is estimated at 48,000 lb. for the engine, 125,000 lb. for five cars, and 65,000 lb. for 500 passengers, or 238,000 lb. in all, the length of the train being 258·95ft. The weight of the cable trains is given by *Engineering News* as 56,000 lb. for a car equipped with electric motors for switching, 120,000 lb. for three cars, and 65,000 lb. for 500 passengers, or 241,000 lb., the length of the four-car train being 200ft.

The position of general manager of the Victorian Railways has been offered to Mr. J. Mathieson, the present Commissioner for Queensland Railways, who has accepted same, at a salary of £3500 per annum, for a term of five years. It is understood that in making the choice of this gentleman, his successful colonial experience in railway matters specially befits him for the position. The successor to Mr. Mathieson for the position he vacates in the Queensland Railways is to be filled either by Mr. Gray, a former commissioner, or Mr. C. E. Norman, the present Engineer-in-Chief for Queensland Railways.

A pre-arranged railway collision is to be one of the attractions at the opening of Buckeye Park, a pleasure resort twenty-five miles south of Columbus, O. The Columbus, Hocking Valley, and Toledo Railway has assigned two 35-ton locomotives, which have outlived their usefulness for economical service, and to each of these will be attached three old gondola cars and a caboose. A siding 1000ft. long has been laid, connected at each end with the main track, and the trains will be started from points about half or three-quarters of a mile from the middle of the siding. A trial trip has showed that a speed of forty-five to fifty miles per hour may be expected. The engines are to carry 120 lb. boiler pressure, and are to have the throttles wide open. What means will be taken to protect the spectators in case of the possibility of a boiler explosion we do not know. The above particulars have been given to the *Engineering News* by Mr. W. H. Fisher, general passenger agent, who is arranging for a large excursion traffic to this novel attraction.

In the report of the trial tests of Victorian coal made on one of the Government locomotives, Mr. Price-Williams, who has recently returned from Australia, says:—"I consider, therefore, that having regard to these exceedingly severe trial tests, carried out as they have been under exactly similar conditions of load, locomotive power, and upon the same portion of the Victorian railways, with the results verified by the independent observations of the officials of the Government railway department, the fact is conclusively established that this great Colony has the good fortune to possess, amongst its other great natural resources, an abundant supply—the extent of which I gather from Mr. Stirling, Assistant Government Geologist, has not yet even been thoroughly ascertained—of coal of a very high class, not only well suited for steam purposes, but which, from independent tests of it which I made at home, I can certify produces very good coke, and from its bituminous character, ought to prove of great value as a gas producer. It is scarcely necessary, I should add, that this coal has all the best qualities for domestic use."

The sale of the Guatemala Central Road, owned by Mr. C. P. Huntingdon, to an English syndicate, has been completed. The price is said to be 7,400,000 dols. in gold. A road is now being built in the northern portion of the State, from Guatemala City, to reach Port Barrios on the Atlantic Coast. This line may divert traffic now going to San Francisco to New York. This road is being built by the Government. The entire distance between the two towns is 180 miles; 65 miles of this, from the Atlantic side, is now in operation. Besides this, 50 more miles are under contract. There is also a 45-mile section from the Guatemala City end to be let to contract shortly. When these two contracts are completed freight can be transferred between the terminals. The coffee shipments then may be made to New York. Another important project by the Guatemalan Government is the spending of 57,000,000 dols. at the new port of Estrapa, nine miles below San Jose. It is at the mouth of a river and dockage will be there furnished for large ships. Over 7,000,000ft. of lumber have been sent from San Fransisco during the last few months. The *Railway News* says the harbour is to become the important one for the Pacific coast in Guatemala.

On March 6th a description was given in The Engineer of the first of the Dunalastairs, a new and powerful class of locomotives built by the Caledonian Railway from designs by Mr. M'Intosh, its locomotive superintendent, for working the heavy main line expresses. The whole fifteen engines of the class have now been running for a period long enough to judge of their working capacity. From the statistics of their work up to the end of April, it is found that with the exception of one instance, where two minutes were lost on account of very stormy weather with a heavy train of twenty vehicles, the whole of the trains have either been worked to booked time, or from ten to twenty minutes made up on the journey. The engines have been put to do single-handed work usually performed by two engines, and have frequently, without the aid of the usual pilot, made up time with trains of from nineteen to twenty-two vehicles over such bad gradients as on the main lines from Glasgow to Carlisle and from Perth to the south. It is intended to gradually conform all the old main line locomotives to this new class by replacing their boilers by large ones of the same dimensions, with 1403 square feet of heating surface.

Cast iron car wheels are not permitted to be used in any country of continental Europe with the exception of Austria, the laws to this effect having originated at a time when such wheels were very imperfect. This arbitrary action, *Engineering News* says, of course prevented any improvement in such wheels, while their general use in the United States has led to great improvements in the design and manufacture of the wheels, and the establishment of a large and important industry. During the past year Mr. Fr. von Emperger, consulting engineer, of New York city, representative of the Austrian Government, was requested to investigate and report upon American practice. As a result of this, the Austrian Government Railways placed an order with the New York Car Wheel Works, of Buffalo, N.Y., for 120 standard cast iron Griffin car wheels for use on freight cars fitted with brakes. These have been delivered, but the cars cannot be used beyond the Austrian frontiers, in consequence of a rule of the German Railway Union—which comprises all the States adjoining Austria—which forbids the use of brakes with cast iron wheels. Should this experience on Austrian railways lead to the abolition of this rule there would be a good prospect for an export trade in this country, as the experience, machinery, and skilled labour necessary for the construction of high grade cast iron wheels cannot be had anywhere in Europe.

NOTES AND MEMORANDA.

A new flour mill is to be built at Fort Saskatchewan, Alberta, the owners of which propose to give 35 lb. of flour, 10 lb. of bran, and 3 lb. of shorts in exchange for a bushel of sound clean wheat.

The deaths registered last week in 33 great towns of England and Wales corresponded to an annual rate of 18·1 per 1000 of their aggregate population, which is estimated at 10,846,508 persons in the middle of this year. In London the rate was 17·8.

The population of registration London at the recent census enumeration was 4,411,271. The population of London in the middle of this year, estimated on the basis of the rate of increase between the censuses of 1891 and 1896, is 4,421,492, which is 14,463 less than the estimate hitherto in use, based on the enumerations of 1881 and 1891.

At a recent meeting of the Paris Academy of Sciences, a paper was read on the *rôle* of the induction ring of iron in dynamo-electric machines, by M. Marcel-Deprez. A discussion as to the cause of the effect produced by the ring of iron in dynamos of the Pacinotti type. Some experiments are cited which tend to show that the explanations usually given in text-books are insufficient. The complete theory will be given in a future paper.

Mr. W. J. Humphreys has examined quantitatively the solution and diffusion of tin, lead, bismuth, zinc, copper, and silver in mercury with a view to determining the extent to which these phenomena differ, if at all, from the solution and diffusion of non-metallic solids in liquids. Pieces of metal were placed on the upper surface of a column of pure mercury, and samples of the liquid were taken at definite depths below the surface, and the amount of foreign metal estimated. As far as the experiments go, the author concludes that the solution and diffusion of metals in mercury do not essentially differ from those of non-metallic solids in liquids. Copper and silver dissolve in mercury to a very small extent at ordinary temperatures, but diffuse very rapidly.

At a recent meeting of the Physical Society, Mr. Campbell read a paper on "New Instruments for the Direct Measurement of the Frequency of Alternating or Pulsating Electric Currents." The author employs two arrangements, in one of which a steel wire, the tension on which is variable, and the other a steel spring of variable length clamped at one end, are acted upon by an electro-magnet through which the periodic current is passed. The tension or length, as the case may be, is varied till maximum resonance is obtained, a small contact piece being employed to detect when this occurs. The instrument exhibited was capable of measuring the frequency of periodic currents of from 40 to 150 double vibrations per second. Mr. Watson said he thought that in the case of the steel spring there would be a considerable temperature correction, and he suggested a method by which this might be compensated.

At the last meeting of the Physical Society, Mr. R. Appleyard read a paper on "Dielectrics." The author has particularly investigated the effect of temperature on the dielectric resistance. He has employed for this purpose condensers insulated with mica and paraffined paper. In order to eliminate some of the effects of surface leakage, Price's guard-ring arrangement was made use of in all the experiments. The author finds that the capacity of a paraffin condenser varies irregularly with the temperature, but that to within the accuracy attainable with his instruments—1 per cent.—the capacity of a mica condenser is constant between 33 deg. Fah. and 110 deg. Fah. If the resistance of paraffin at a temperature t is represented by $R_t = R\,a^t$ the mean value for log. a deduced from all the author's measurements is $\bar{1}\cdot96344$. Experiments made with a parallel plate condenser, with paraffin as the dielectric, show that when the temperature reaches within about 20 deg. of the melting point, the resistance rapidly falls; when melting commences there is a rapid drop, but while melting is in progress the resistance remains constant.

Another method of treating wood, with a view to preserving and colouring it, is described in a recent English patent specification. Although the lighter paraffin oils are said to protect timber, they disappear after a time through rain and climatic influences, leaving only the heavier oils in the wood, and these are sufficient to protect the timber from decay. The new method consists in taking the heavier oils or waxes of the distillation of mineral, animal, or vegetable oils and mixing them under pressure and at an elevated temperature with naphtha or other solvent. The solution is then forced into the wood in the same way as when creosoting is adopted, after which the naphtha is recovered from the wood by distillation, leaving the heavy oil in the timber to protect it from decay. By this means a small amount of heavy oil will thoroughly preserve wood, whilst the latter will be clean to work and handle, and remain light and elastic. It is claimed that only one-fifth the weight of heavy oil is required compared with creosote. For colouring the wood, such dyes are used as are soluble in the solvent employed to dissolve the oils, with which the wood is being treated.

In a paper in the *Journal* of the American Chemical Society, on "Coals, Determination of their Heating Effects," by W. A. Noyes, J. R. McTaggart, and H. W. Craven, references are given to the recorded discrepancies found by Scheurer-Kestner and others to exist between the calculated and the determined calorific powers of coals. The authors have tested six specimens of representative Indiana coals by the Hempel calorimeter, by Berthier's test, and by analysis; two of these coals—Brazil and Lancaster—are non-caking, and are known as block coals, whilst the other four are bituminous caking coals. Anthracite could not be compressed into cylinders for the calorimeter, and could not be burned as a powder; it was therefore not tested. The moisture was found by drying at 105 deg. Cent. for an hour in a toluene bath, and the fixed carbon by heating one gramme of the coal in a covered platinum crucible with the full flame of a Bunsen burner for seven minutes; the oxygen was estimated by difference, after adding to the weight of ash found, five-eighths of the weight of sulphur present, as the sulphur generally occurs in the form of pyrites, which is assumed to be burned to Fe_2O_3 and SO_2. The calorific power is calculated from the formula $8080\,C + 28{,}800\,(H - \frac{1}{8}O) + 1582\,Fe + 2168\,S$, the symbols standing for the weight of the corresponding element present, and hydrogen being supposed burnt to vapour of water.

According to the statement made by Mr. H. Schweitzer, of New York, some of the refiners of American petroleum have a new way of adulterating their products. This consists in making up oil from a mixture of "top and bottoms"—*i.e.*, naphtha and the last boiling, or heavy oil. It is stated that these mixtures can be made to show the same flash-point and specific gravity as the best burning oils; and as the boiling point is also the same, only an exact fractional distillation would furnish means for detecting the adulteration. For this purpose, Mr. Schweitzer advises the use of the solidifying test generally, which also shows the amount of solid paraffins present in the oil. Upon this the *American Manufacturer* says:—Herr R. Kissling remarks that he has used the solidifying test daily for at least twenty years, not because of its supposed value as a test of the burning and illuminating power of the oil, but because the separating out of the paraffins in cold weather might give rise to great inconvenience. For applying the test, Mr. Kissling makes use of an appliance consisting of a couple of concentric tin cylinders, containing a mixture of ice and salt. Into this, standing upon a cork plug, is inserted the oil in a glass tube which also contains a thermometer. According to Mr. Schweitzer, one of the large American railways companies demands that oil flashing at 150 deg. to 175 deg. shall remain clear when cooled and kept for ten minutes at 1 deg. Fah.; and 300 deg. oil must remain clear when cooled to 32 deg. Fah.

MISCELLANEA.

The directors of the Brush Electrical Engineering Company have decided to make a large extension of their works at Loughborough for building the Raworth Universal steam engine. The new tool shop, which will be devoted entirely to the engine trade, is to be 160ft. long by 48ft. wide. Building operations have already commenced, and it is hoped that delay in the execution of orders will now be avoided.

At Klausthal, in Germany, according to *Machinery*, a lightning stroke struck the wooden post of a house and fused two nails four millimetres thick. Messrs. Siemens and Halske, of Berlin, afterward carried on a series of experiments to ascertain the force required to melt this quantity of iron. Assuming one second as the time standard, it required a current of 200 ampères and 20,000 volts, representing 7000-horse power. Assuming that the lightning occupied one-tenth of a second to fuse the two nails, the horse-power required would be 70 000.

Considerable inconvenience was lately caused to the Howrah public through the bursting of a main of the recently opened Howrah water supply in the Grand Trunk Road, near Bally. So great was the rush of water that it literally cut through the road, rendering wheeled traffic altogether impracticable, while considerable inconvenience was caused to foot passengers. Some of the villagers of Bally regarded the accident as most opportune, as two or three dried-up tanks were replenished with the much coveted filtered water. The damage was quickly repaired and traffic was resumed.

The Port Orchard dry dock, built for the U.S. navy at Seattle, Wash., was formally opened on April 23rd by the entrance of the monitor Monterey. The dock is of timber construction. The contract for the work was awarded in October, 1892, to Byron, Barlow, and Co. The general dimensions are as follows:—Length over all, 749ft. 8in.; length over coping, 650ft. 5in.; length on floor, 573ft. 7in.; width over coping at middle, 130ft. 1in.; width on floor, 67ft. 1in.; width of entrance, 92ft. 8in.; height from floor to coping, 39ft. 3in.; height from sill to high-water line, 30ft.; height from keel blocks to high-water line, 28ft. 2in.

On the 17th ult. a converter in the American Glucose Company's works at Peoria, Ill., exploded with terrible effect, two men being instantly killed and several others being dangerously injured. The converter, which was of copper, 5ft. in diameter and 14ft. long, was used to convert liquid starch into glucose, steam being used in the process. When the accident occurred, it is said that there was no way of shutting off the steam outside of the room in which the explosion occurred, and the converter-room could not be entered to remove the injured until the fire had been drawn from the boilers, and the latter cooled down. The *Peoria Journal* stated that the copper shell of the converter was ⅜in. in thickness originally, but it was worn down to ⅛in. by the corrosive action of the acids.

In the United States, during the year 1895, occurred 355 boiler explosions. This, says the *American Miller*, is the number tabulated by the *Locomotive*, and is probably short of the true number. By these explosions 374 people were killed and 519 injured. The property loss is not stated. In the preceding year the number of explosions was 361, and in 1893, 316. Inspection of boilers and examination of engineers is not general, and even where the law requires both politics is an ever potent factor. So long as inspection fails to inspect, so long will carelessness and ignorance continue the work of destruction, ably supported by the short-sighted economy of a large percentage of plant owners. Time will press home the importance of inspection and supervision; no doubt of it; but meantime the sacrifice of life and property will continue.

A most sensible order has been issued by the Commissioner of Public Works Collis, of New York City, who has directed that whenever an application for a permit to open a street is filed, all other parties having conduits in that street shall be notified to apply for permits to do any work they have in contemplation, so that the street may be blocked for as short a time as possible. After repaving, on completion of such work, the street will not be torn up again for a year except in great emergencies. Gas companies laying mains in streets will hereafter be required to lay service pipes to all properties abutting on the street while the main is being laid, and no permits for service pipes will be issued afterwards. Many hundreds of thousands of pounds would be saved annually, to say nothing of the great saving of annoyance, if a similar order were observed in London.

The Arrogant, a new second-class cruiser of 5750 tons, was successfully launched on Tuesday, at Devonport Dockyard, in the presence of a large concourse of spectators. The christening ceremony was performed by Lady Forestier Walker, wife of the General Commanding the Western District. The building of the Arrogant was commenced in June, 1895, and another twelve months must elapse before she is ready to hoist the pennant, by which time she will have cost nearly £270,000, more than half of which sum has been already expended on her. The Arrogant was designed by Sir William White, is 320ft. long and 57½ft. broad. Earle's Company, Hull, are the contractors for the engines, which are expected to develope a mean speed of 18·5 knots. The vessel's armament will comprise altogether twenty-seven quick-firing and machine guns, and two submerged torpedo tubes.

In 1895 a total of 3434 vessels, with a tonnage of 8,448,383 tons, traversed the Suez Canal, paying tolls amounting to 75,934,357f. The toll for the 216,938 passengers produced 2,169,385f., and the accessory earnings 322,367f., making a total for transit of 78,426,110f. The number of vessels in 1895 that used the canal for the first time was 250. Three thousand two hundred and sixty-six vessels, or 95·1 per cent. of the total shipping, used the electric light, enabling them to continue their passage through the canal during the night. In 1894 the proportion was 94·9 per cent. The average time occupied by vessels in the canal during 1895 was 19 hours 18 min., and the average duration of steaming through the canal 16 hours 18 min. Compared with 1894, that represents a diminution of 37 min. in the time occupied by vessels in the canal, and of 23 min. in the actual steaming through it. In 1895 the number of vessels drawing over 7 m. of water that passed through the canal was 1250, and among those vessels there were 228 that drew from 2 m. 51 cm. to 7 m. 80 cm., the maximum permitted by the regulations of navigation. The average tonnage of vessels using the canal increased from 2398 tons in 1894 to 2460 tons in 1895.

The German Hygienic Association offers a prize of 1200 dols. for a research essay on the efficiency of electric heaters. The programme is as follows:—"The heat given out in heating installations by heaters in their various forms and modes of use is to be ascertained. The investigations are to be described in detail in respect to the arrangement of the heaters, the nature of the heating agents, and the observations made; and they are to be illustrated by drawings. The heating values obtained are to be stated in units of heat given off per hour per unit of surface. In the case of heat given out to air, the investigations must be conducted with currents of air at speeds as different as possible. The heaters are to be described in detail as regards form and measurement, and the relation of their heating efficiency to their weight is also to be ascertained." Essays are to be written in German, and sent, with a motto and sealed envelope, to Prof. Konrad Hartmann, Charlottenburg, Fasannstrasse, 18, before the 1st of July. The essay will remain the property of the successful competitor, but he is required to publish it within six months, and to give the prize offerers gratuitously 300 copies. The offerers reserve the right to divide or withhold the prize

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies*

H. A.—*Thanks for the cutting. We agree with you that the invention does not deserve the encomiums heaped upon it. If, however, it provides a satisfactory method of getting rid of coke at a fair price, the gas companies will regard it with much favour.*

MARINE GOVERNORS.

(*To the Editor of The Engineer.*)

SIR,—I shall be obliged for name and address of maker of Smith and Pinkney's Pendulum Governor for Marine Engines, or if not now made by any one, about the date when patent was taken out for it.

Newcastle-on-Tyne, May 27th, 1896. C. W. F.

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. *£0 14s. 6d.*
Yearly (including two double numbers) .. .. *£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate or any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
Half-yearly .. .. *£0 18s. 0d.*
Yearly .. .. *£1 16s. 0d.*
THICK PAPER COPIES—
Half-yearly .. .. *£1 0s. 3d.*
Yearly .. .. *£2 0s. 6d.*

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, June 2nd, at 8 p.m.: Annual General Meeting of Corporate Members only, to receive the Report of the Council, and to elect the Council and Auditors for the ensuing year.

GEOLOGISTS' ASSOCIATION.—Friday, June 5th, at 8 p.m.: Lecture, "Bradyseisms, Earthquakes, and other movements of the Earth's Crust"—Geodynamics—by Professor John Milne, F.R.S. Saturday, June 6th: Excursion to the Crag District of Suffolk. Leave Liverpool-street—G.E.R.—10 a.m., arrive Bentley Station 11.45. Excursion Secretary, A. C. Young, 64, Tyrwhitt-road, St., Johns, S.E.

SOCIETY OF ENGINEERS.—Monday, June 1st, at 7.30.: Paper to be read, "Examples of Railway Bridges for Branch Lines," by Mr. M. A. Pollard-Urquhart, M. Inst., C.E. Synopsis:—Cost and number of railway bridges—Investigation as to the cheapest form—Public road bridges over railway—Wing walls—Economy of brick arch over girders for single line—Three arch bridges—Public road bridges under railway—Types of flooring—Occupation road bridges—Timber bridges for farm traffic—Structures over watercourses—Examples of three different types—Conclusion.

ROYAL INSTITUTION OF GREAT BRITAIN.—Tuesday, June 2nd, at 3 p.m.: Lectures: "The Building and Sculpture of Western Europe," by Professor T. G. Bonney, D. Sc., LL.D., F.R.S. Wednesday, June 3rd.: "The Vault of the Sixtine Chapel," by Professor W. B. Richmond, R.A. Thursday, June 4th.: "Lake Dwellings," by Mr. Robert Munro, M.D., M.A. Friday, June 5th, at 9 p.m.: Discourse, "Electric and Magnetic Research at Low Temperatures," by Professor J. A. Fleming, M.A., D. Sc., F.R.S., M.R.I. Saturday, June 6th, at 3 p.m.: Lecture, "The Moral and Religious Literature of Ancient Egypt," by Dr. E. A. Wallis Budge, M.A., Litt. D., F.S.A.

"THE ENGINEER"
HORSELESS CARRIAGE COMPETITION.

WE have recently received suggestions from many quarters that it would be expedient that our Competition should be postponed until the spring of next year, for the reason that the date already fixed does not allow sufficient time to competitors to produce really satisfactory vehicles for trial, and, further, that until the Bill now pending in Parliament has been passed, designers cannot be quite sure that they are working on the right lines. So far as we are concerned, we are perfectly ready and willing to abide strictly by the conditions which we have already published, but we shall be glad to have the views of those who are interested, so that we may decide upon a course which will lead to the best results for all.

THE ENGINEER.

MAY 29, 1896.

THE PNEUMATIC PROCESS.

WE have recently published two long communications from Sir Henry Bessemer intended to refute certain statements made by Mr. Weeks in the course of a presidential address to the American Institute of Mining Engineers in February last. Mr. Weeks gave a Mr. Kelly the credit of inventing something which he regards as an anticipation of the inventions of Sir Henry Bessemer. We use the word "something" advisedly. The term is vague, and we intend it to be vague, for reasons which will, we think, be made sufficiently obvious before we have done. We may say that with the controversy we have hitherto had nothing whatever to do. We did not publish Mr. Weeks' address; we did not give currency to any attack on Sir Henry Bessemer. We have published his letters out of deference to the wishes of the veteran inventor, feeling certain the while that they would prove more or less puzzling to the greater number of our readers, dealing as they do with the facts of a long-forgotten episode. Mr. Weeks has now sent us a statement of his views, which will be found in another place, and the time has come when the matters at issue must be stated in a form more intelligible than that adopted by our correspondents. Fortunately the thing is very simple. Mr. Kelly many years ago carried out experiments in the purification of iron by blowing air into a small vessel containing molten cast iron. Mr. Weeks and many other persons before and since have claimed that this was an anticipation of the Bessemer process. No one, however, so far as we are aware, has asserted that Sir Henry knew anything of Kelly or his experiments when he took out his first patent.

The first thing to strike the dispassionate reader who has a competent knowledge of metallurgy is that the contest has, in the first place, no practical value or significance whatever. How, indeed, it may be asked, were Kelly's operations an anticipation of the Bessemer process? In the second place, it will appear to him that the something fought about is not worth the paper and ink spent in the dispute. It is beyond all question that Kelly's experiments ended in absolute failure. No one asserts that he ever produced a ton of marketable steel. At the bottom of a little fixed cupola he put a hollow fire tile. The top or uppermost wall of this tile was pierced with small holes. A tuyere led air into the hollow tile, and the air escaped or was intended to escape up through melted iron in the cupola. It may be said that this was the Bessemer process. It was also said that Bessemer was anticipated by Martien, because he proposed that air should be made to pass up through molten iron running in "sows." It was also said that he was anticipated by some one who had dipped a tuyere below the level of melted metal in a ladle. The Catalan hearth and the Welsh refinery fire have all been cited as anticipations, and they have all been very properly brushed aside. A statement contained in Mandilso's Travels in Japan has been adduced to prove that the Japanese practised the process in 1669. Parry's abortive experiment at Ebbw Vale was far more to the purpose than anything Kelly did. Probably, if credit is to be given to any inventor before Bessemer, it is due to Henry Cort, who invented the puddling furnace, in which oxygen obtained from the oxides with which the hearth is fettled rises through the molten metal, and aids in burning out the carbon and silicon. But all arguments and citations of this kind are beside the mark. The Bessemer process, as it has come to be called, is not *a* thing. It is made up of a dozen things. Kelly most certainly did not invent all these things; neither did Sir Henry Bessemer. Kelly invented a process that was of no value whatever. The mere blowing of air through molten iron approaches very nearly to the nature of a principle, and a principle cannot be made the subject of a patent. But Kelly did not stand alone. Dozens, if not hundreds, of attempts have been made to free iron of its impurities. These are forgotten, simply because they were utter failures. Why should Kelly's utter failure be singled out from the host? Simply because there appears at first sight to be a close connection between the principle of his apparatus and the inventions of Sir Henry Bessemer. But the radical difference remains that, whereas Bessemer was successful, Kelly was not. It has been abundantly proved that the mere blowing of air into melted cast iron will not now and never has produced satisfactory commercial steel; and it is not easy to see why, on the one hand, Mr. Week's should have taken the trouble to rake up Kelly's long-forgotten existence; or, on the other, why Sir Henry Bessemer should so earnestly maintain that he was the original inventor of a method of treating cast iron which, standing alone, is absolutely worthless. It is indisputable that Kelly did such and such things, but what if he did? Sir Henry breaks a butterfly on the wheel when he disputes with Mr. Weeks. Besides the whole matter is ancient. It is some forty years since Kelly made his experiments. It is at least as many since Bessemer tried his hand at the same work. His reputation has lasted too long to be affected one way or the other now by experiments which ended in total failure.

A noteworthy feature of the controversy is the action taken by the United States patent tribunal, and the facts stated by Mr. Weeks are interesting. At first sight it seems that the decisions cited by Mr. Weeks are conclusive evidence that the claims advanced for Kelly were substantial and substantiated. But it must be remembered that the limitations of patent law are very rigid in one sense though very vague in another. There is beyond all question what may be termed "technical anticipation," and it constitutes one of the terrors of United States patent law. In the eyes of the examiner, things apparently alike are not infrequently really alike. Even in this country it has been possible to find what was little more than a published suggestion regarded as an anticipation, and a paragraph in a newspaper has ere now been regarded as sufficient to invalidate a patent; but newspaper paragraphs neither make nor mar a reputation, albeit nothing is more vexatious than the manner in which words have been used to establish priority claims. The reputations of great inventors are fortunately not measured and determined by patent law; they rest on a far wider basis. The world has never given either honours or money to an inventor who did nothing but file a specification. After all, the honours and the money go to the man who does, not to him who merely suggests. Sir Henry Bessemer's claims to honour and fortune are entirely unaffected by the fact, be it true or false, that Kelly or any one else tried to blow air through cast iron to purify it. Bessemer did that, and a great deal more. It is often urged by his detractors that without the aid of Mushet he could have attained no success. But even that statement is only true within very strict limits. Regard the case how we may, award credit with no stinting hand, as we do, to a number of inventors and workers, the broad great fact remains that to Henry Bessemer the world is indebted for the art and science of purifying iron by blowing air through it. His work extended over years, and ultimately it was his good fortune to gather round his standard a group of metallurgists and engineers by whom the multiplex manipulations which go by the general name of the Bessemer process were suggested or improved, and the apparatus for carrying them on produced. It is only necessary to go into any great modern steel works, see the huge blowing engines, listen to the roar of the converter, and watch the cascade of fiery white metal falling into the ingot moulds to see how vast is the difference separating Bessemer from Kelly. The Bessemer process is not a theory, it is an art. It is not one invention but fifty. Kelly's cupola did not anticipate the Bessemer converter as fully as Newcomen's engine did the modern triple-expansion engine. For Newcomen's engine could work; it had an economical value; it revolutionised the practice of mining. But Kelly's experiment possessed no value whatever; it rather tended to retard than to facilitate progress, as is the way with experiments which fail.

WHAT IS AN INVENTION?

IN THE ENGINEER for August 16th, 1895, will be found an article entitled, "What is Invention?" We commented at length on the views advanced by Mr. W. H. Smyth, mechanical expert and consulting engineer, living in Berkeley, California. Mr. Smyth has read what we have said, and still holds to his original views. He has favoured us with copies of the *Mining and Scientific Press*, containing a paper from his pen entitled, "Invention: the Indispensable Requirements of the Patent Law." We reproduce the paper, because it gives some useful information concerning the legal aspect of patents in the United States. Mr. Smyth's argument is not very clear to us, and we hope that he will forgive us if we do not fully grasp his meaning. We understand him to say that the word "invention" should be eliminated from patent law, and that in its place should be used the words "discovered," "produced," "thought," or "reasoned out."

Very recently we took occasion to point out that, in a certain sense, every invention is in the nature of a discovery. A discovery cannot be patented; but the means by which the discovery can be made useful can. Thus, for example, it was discovered that the electric current could deflect a magnetised needle. But the apparatus by which this discovery was utilised in the telegraph was invented. The discovery was common property as soon as it was announced. It remained open to each inventor of apparatus to choose a different method of utilisation. There are, however, cases in which a discovery is kept secret and utilised. An instance is furnished by the well-known Bessemer "gold" paint. Sir Henry, then Mr., Bessemer, in trying to make "gold" and "bronze" paint from Dutch metal, discovered a fact and utilised it. The whole story is extremely interesting. We hope the inventor will record it in his forthcoming autobiography. He kept the secret, and made his paints; and the object of thus keeping the secret is very suggestive. The whole success of the paint turned on one point. A certain result had to be produced at one stage of the process. Now this result might have been got in more ways than one, and Mr. Bessemer must, to protect himself, have taken out either a number of patents, or one combination patent. In either case it would be impossible to be sure that he had covered the whole ground and left no loophole for another inventor. Fortunately the manufacture was of such a nature, and the trade in gold and bronze paints so concentrated, that he had no difficulty in keeping the secret and supplying the demand. But however near to discovery invention may come, it is not invention. We think that the weakness about Mr. Smyth's argument lies in the circumstance that he mixes up two distinct things, namely, invention and an invention. So far as we can see, a judge is not called upon to define invention in any direct way; but he may be called upon to say whether a particular machine, or process, or thing, is, in the legal sense, an invention or not. The United States Patent-office, says Mr. Smyth, "refuses to grant a patent, not on account of lack of novelty, for no anticipatory device can be found. It is admittedly of great practical importance, but it is refused simply on the ground of want of invention." That is to say, the Patent-office holds that some device is not an invention. In this country the law is administered in a different way, and we have no hesitation in saying that Mr. Smyth has only told half the truth about the American system. Certain novel wants are called into existence as civilisation progresses. These wants are daily supplied by individuals who are not aware that they are doing anything unusual. The method of supply is simple, and obvious not only to one man but to hundreds of men, and the result is novel and satisfactory, but there is nothing to patent. Take, for example, the shafts of a dog cart. It was found that these, if made of wood only, broke, so a strap of iron was put under each to strengthen it. The addition of an iron plate in this way is obvious, and required no inventive effort, and would not form a good subject for a patent; and notwithstanding Mr. Smyth, we suspect that the United States Patent-office authorities find no practical difficulty whatever in defining what is and is not a patentable invention, although they may be quite at a loss to define "invention."

We have on a previous occasion said that Mr. Smyth's mode of reasoning leads us to believe that he has himself never invented anything. If he had, we venture to think that he would not have experienced the incredible difficulties under which he seems to labour in defining the meaning of the word. We have so fully dealt with the question in our issue of August 16th last year, that we shall not now say much concerning invention; but it is, no doubt, worth while to consider what is the essence of an invention—the something that distinguishes it from more or less well-known machines, instruments, appliances, or processes. Confining ourselves to machines, an invention, so far as it is capable of definition at all in this connection, may perhaps be said to be a combination of parts arrived at by an individual, and apparently, or as far as is known, not likely to be conceived by others. Put into other words, all machines are combinations of well-known parts. The particular combination in question must not be an obvious combination. It must be more or less occult, and the more occult the more deserving of a patent. Very many cases might be cited in illustration; indeed, they are multitudinous. Yet it may be useful to name one. Blake's stone breaker will do as well as another. It is composed of well-known parts, an excentric, a couple of toggle joints, a swinging jaw, a spring to pull the jaw back, loose plates to do the chewing, which can be renewed at will. The world had been breaking stones for thousands and thousands of years. But until Mr. Blake came on the scene, no one ever thought of combining the parts we have named in one harmonious and disintegrating whole. We have heard it said that the entire device was so transparently simple and obvious that it did not constitute an invention at all. No such reasoning, however, could have weight for a moment in the face of the fact that, as we have said, millions of individuals must have broken stones, and blistered their hands, and used bad language for century after century, and yet had not hit upon the combination which, in a sense, rendered Mr. Blake immortal.

In this country the views we express are very generally held, and an invention is generally defined as a combination of parts, not only useful, not only novel, but occult or not obvious. How or by what means the arrangement has been schemed, effected, or worked out, has nothing to do with the subject in hand. That affects the validity of a patent in quite another way. No doubt in this country, as well as in the United States, obvious combinations are not good subjects for a patent. The question has repeatedly been raised in our law courts. It has been urged that certain combinations were so obvious as to need no invention to produce them, so that they were not inventions. But without going into legal subtleties of definition, common sense teaches us that if a machine which has been wanted for some time, either positively or vaguely, at last appears, the combination is not obvious; because had it been obvious the want would have been satisfied long before. The cases cited by Mr. Smyth may or may not prove his case. We are unable to say whether they do or not, because we know nothing about the facts; but we venture to think that in all of them the combination patented, or tried to be patented, was obvious, and did not constitute an invention.

We think we hear it urged that, after all, we have defined a new combination of parts as a good subject for a patent, although the combination might demand no inventive effort whatever. Our reply is simply that it remains to be proved that any new combination of parts can be effected without invention. There are many kinds of invention. There is the happy idea, the inspiration, the thought, which comes quickly as a flash of lightning; and there is the result slowly arrived at by the painful mental process of trial and error; and between these extremes is a field of mental work, indefinable; now with, now without law and order. It is a vain thing to attempt to say what is and what is not invention. But it is by comparison very easy to say what is and what is not an invention; yet the decision is reached, and our minds made up on a basis which has very little to do with explanations of the nature of the inventive faculty. And so we hold that the words "an invention" are good and expressive, and that Mr. Smyth has failed to make out a case for their suppression. It seems to us that to substitute "discovered" or "thought out" for "invented," as Mr. Smyth proposes, would carry us no further. All the old familiar arguments would apply to the substituted words as forcibly as they have been used in respect of "invention."

THE ENGINEERING SETTLEMENT.

It is with much satisfaction that we observe the close of the Whitsuntide holidays, is accompanied, as usual, by a return to work on the part of the operative engineers of the North-east Coast, instead of, as was at one time feared, by empty benches and silent machinery. Fortunately, a considerate and wise policy of concession on the part of the employers has obviated the idleness of from 10,000 to 12,000 members of the Amalgamated Society of Engineers, and the idleness also of 15,000 members of the subsidiary trades. The employers have been advised that the construction of the agreement for the advance of wages to the members of the Amalgamated Society of Engineers should rest upon the literal interpretation of the written terms, irrespective of any verbal explanation given at the time of signature. They have therefore decided to give operation to the agreement as it stands, and to give a general advance of 1s. in September next. It is distinctly understood that an amnesty is declared on both sides. Under this agreement the whole of the members of the Amalgamated Society of Engineers, including metal placers, drillers, borers, and other machine workers, will receive another shilling a week advance in September next, in addition to the one they obtained last month. The men who have been on strike at Stockton, Hartlepool, and Middlesbrough have returned to work. The men on the Tyne and Wear have also withdrawn the notices they had handed in to cease work, so that there will be no interruption of employment whatever on these two rivers. The settlement means that the arrangement as to wages made on the 31st March is to stand in its entirety. That is to say, it is to apply to all the members of the Society—to those who are in receipt of wages below 30s. as well as to the others. We think the men may consider themselves fortunate to have obtained such a termination to the dispute as this. The employers might easily have argued that in a question of this kind it ought not to be a matter of rigid and literal rendering of an agreement, apart from its spirit and intention. At the same time, considering in any case that the dispute was about a matter that will not take effect for several months, that it is in its essence a comparatively small point, and that, on the other hand, a stoppage of work at this time would certainly be disastrous to all concerned, we think the employers have done well and wisely in yielding the point rather than involve the district in a labour war. If the men will not consider themselves or others, the employers must consider both.

THE COST OF A GREAT FROST.

Sheffield was the city which suffered most severely of all provincial places of first-class importance from the great frost of 1894-95. Our Sheffield correspondent, writing at the time, estimated the cost to the Corporation Water Department in repairing burst pipes and arrangements for making supplies by water-carts and other means at a sum certainly not less than £10,000. The accounts of the Water Committee for the year ending March 25th, 1896, have just been published. They exhibit a total cost of £10,620, "extra expenditure caused by the severe frost." This sum is considerably in excess of what was officially thought of at the end of 1894, but the water manager explained that the damage done to the distributing pipes and other apparatus was only partially disclosed prior to March 25th last year. In the accounts, indeed, up to that date, the exceptional expenditure then ascertained was only £1156 5s. 10d., the larger portion of that amount having been incurred in repairing fractured mains, &c. It was after 1895 commenced that the real magnitude of the calamity became apparent. Lengthy pipes were taken out, only to be succeeded by fresh bursts within a few yards of where the repairs had been completed. The enormous extent of the damage may be gathered from the fact that the mains thus repaired or relaid amounted to an aggregate length of 31,519 lineal yards, or 17¾ miles. The number of applications made direct to the department by consumers whose pipes were frozen or burst, or otherwise deprived of water, was over 16,000, in addition to which 10,925 applications were received from plumbers requiring water to be shut off for repairs where stop taps were not fixed. Notwithstanding that the resources of the department were principally devoted to restoring the permanent supply of water to the consumer at the earliest possible moment, the department repaired upwards of 7000 lead communication pipes belonging to owners or occupiers of property. The draught upon the system caused, of course, by these fractured pipes, reached a maximum of 16,000,000 gallons per day, as compared with the normal daily consumption of about 7,500,000 gallons. It was not until the second week in August, 1895, that the normal consumption was restored. While £10,620 15s. 3d. was the cost to the Corporation Water Departments, the consumers had further losses inflicted upon them. Many works were altogether stopped, artisans thrown out of employment, and business dislocated. The indirect loss caused by the frost would not be over-stated at nine times the direct damage done to the Corporation system.

MORE LIGHT.

According to telegrams in the pages of our daily contemporaries, Mr. Edison has made important discoveries in connection with the Röntgen rays. By coating a Crookes' tube on the inside with fluorescent crystals, a pure white glow resembling sunlight is produced. We are too much accustomed to vague comments of this kind concerning Edison's work to attach much importance to this. More interesting is the statement that Tesla has at last discovered that of which he has so long been in search — a method of inducing millions of etheric vibrations per second within a vacuum tube—without using any direct electrical connection. An ordinary 16-candle bulb gives by this method, we are told, a light equal to 250-candles, which is sufficient to light very pleasantly a large room. It is rapidly becoming obvious that the received theories of light are quite inadequate to explain new discoveries. It may yet be found that there exist means of transmission of energy of which we have no mechanical analogue, no mechanism, in fact, which is understood. Dr. Lodge hinted at this some years ago when he said, after dealing with certain aspects of the vibratory theory, "Perhaps, after all, there is no motion."

LITERATURE.

The Progress of Artillery—Naval Guns. By James Atkinson Longridge. London: E. and F. N. Spon. 1896.

There has been growing during the last few years a feeling in the minds of ordnance engineers that the length of guns has reached the practical limit, and that a reversion in favour of shorter guns is to be expected at no great distance of time. The curve has reached the highest point, so to speak, and will probably begin soon to start down hill. Mr. Longridge is the champion of short guns, and in the pamphlet which we have before us he advocates a revolution in the construction of ordnance. If the system he indicates was at once adopted we should have, instead of a gradually descending curve, an almost straight drop from guns of forty calibres and upwards to guns of half that length and less, and a corresponding rise in maximum powder pressure from, say, 15 or 20 tons to about 30 tons per square inch. We are not only too conservative to wish to see so sudden a change, but we are at the same time not convinced in spite of Mr. Longridge's sensational figures, that the modification suggested would be one of unqualified good. It is not enough by any means to show that an increase of pressure means an increase of muzzle energy or a reduction in the length of the piece. There are so many factors to be considered that it would be unwise in the absence of experimental data to insist that what on paper appears best would in practice be so. Mr. Longridge probably recognises this quite well, and we do not quarrel with him for stating his case in the brightest and most forcible terms; what we wish to insist on is that as we are practically without experience in the use of high pressures in guns, it would be unwise to accept the conclusion at which he arrives, that such pressures must be efficient, until exhaustive experiments have been conducted. For ourselves, whilst we are distinctly in favour of the shortening of ordnance, we think it better to maintain the energy by a more efficient consumption of the explosive employed than by greatly increasing the pressure. By this we mean that the direction of investigation at present should be towards the discovery of a method by which a maximum pressure of, say, 15 or 18 tons would be maintained for at least half the length of the gun, and thence drop to such a pressure at the muzzle that the velocity of the gases through the mouth should just equal, or slightly exceed, the velocity of the projectile. By this means a great efficiency would be obtained from an explosive charge, and a gun of moderate length would be as effective as the present very long pieces. The difficulties here are to be faced, as Lord Armstrong said many years ago, by the chemist and the physicist, rather than by the engineer.

It will be well, perhaps, before we enter more fully into a discussion of Mr. Longridge's paper, to lay briefly before our readers the objections to very long guns, that they may appreciate more fully the advantages that would be gained by reducing the length of future pieces. It must be understood that our remarks apply chiefly to guns of large calibre, and to none of less than 4in. These objections are twofold, and can be classed as:—(1) Constructional; and (2) manipulative difficulties. Under the first head the greatest trouble is found in keeping a very long gun perfectly straight; indeed, we may safely say that now-a-days no gun of over 4in. calibre is quite straight. Bending occurs not only because the weight of the gun itself is more than the gun is able to support, but because the contraction of long hoops on to a barrel sets up unequal strains which pull an originally straight tube into all sorts of shapes. The greatest care in construction is not competent to prevent these unbalanced effects. Another cause is that after the first round has been fired from a gun, a totally new lot of strains is set up; the various hoops, or the wire, as the case may be, readjust themselves under the extension of the piece longitudinally and transversely, and under the high temperature of the explosion. We merely hint at these things. Then it will be easily comprehended that every foot added on to a tube or barrel increases the difficulty of turning and boring it as exactly as is required in the construction of guns, and at the same time the difficulty of forging is greatly increased. All these things combined add enormously to the cost of construction. The manipulative difficulties will probably be sufficiently obvious to every one. The longer and heavier a gun, the stronger must be its emplacement and mounting; the evil effects of unequal heating increase as the length of the gun increases; and the awkwardness of housing and other minor points must not be overlooked. All these objections are balanced by an economical consumption of powder and great muzzle energy.

Let us now turn to Mr. Longridge's pamphlet. The author begins by comparing the ballistic results of the old and the new powders in the old and the new guns, and shows that whereas the increase in muzzle energy due to the length of piece alone, supposing everything else the same, is only about 22 per cent.—a result, by the way, which we have checked independently and found approximately correct, though a slip occurs in Mr. Longridge's figures—whilst the increase in power per pound of powder from old to new is nearly 284 per cent.; from which, of course, is derived the evident conclusion that "the real cause of the great increase in ballistic effect is chiefly the change of the powder." But he opposes the belief that any great improvement in sustaining power has been gained by the adoption of the so-called slow-burning powders, and seeks to support this view by a diagram which "represents the actual pressures obtained from a 6in. gun by Sir Andrew Noble, with a charge of 27 lb. of cordite." This diagram, however, as it stands alone is worthless; it is only by comparing it with a diagram taken from a similar gun using quick-burning powder that the great improvement gained by the use of the new powders can be appreciated. With the old powders the pressure rose to a maximum in about 1⅓ calibres; with the new powders the maximum is not reached till, say, 4½ calibres travel of projectile, and thence the curve falls at about an angle of 40 deg. to the horizontal in an approximately straight line, finally sweeping off at a very small inclination to the horizontal. The curve with the old powders is much steeper. A fair comparison should be made by subtracting the area of one diagram from that of the other, and the increase of power would then be seen. In the next section the author shows that the increase of muzzle energy is not directly proportional to the length of the gun, but is a continually decreasing quantity. Thus lengthening the 6in. gun from 20ft. to 40ft. adds only 54 per cent. to the energy, and putting on another 20ft. adds only a further 16 per cent. to the energy. "It is therefore obvious that guns of extreme length do not give increase of power in anything like the proportion of their length; and taking into consideration their unhandiness and liability to damage due to their excessive length, we cannot look to any improvement of ballistic power by still further lengthening the guns. In fact, they are already too long." And "there remains for consideration the question of increase of ballistic power by altering the conditions under which the powder is used, and this at once raises the question of an increase of the maximum pressure." Mr. Longridge then goes on to show that only about 10 per cent. of the possible maximum pressure from cordite is now used, and this is because up to the present guns have not been constructed strong enough to withstand a higher pressure. He considers, however, that with the system of wire construction, there is no reason why pressures of from 30 tons or 40 tons per square inch should not be used "*with as great a margin of safety* [the italics are the author's] as the forged steel gun previously in use under a pressure of 17 tons per square inch, and with far greater security as regards defects of material and workmanship." This is true to a large extent, but still the wire gun is not wholly without disadvantages, and though these drawbacks would be greatly minimised by shortening the gun, it is not after all a perfect system. However, the greatest objection to the use of these high pressures is, as Mr. Longridge admits, the high temperatures which it involves, and the consequent injurious effect upon the barrel; it is also not improbable that if the gun became very hot the value of the wire winding would be considerably decreased by expansion under that heat. Another objection which is brought forward is the difficulty of obturation, which Mr. Longridge considers can be obviated by the use of the De Bange obturator. To this it may be replied, that even under the moderate pressure now used, the pad occasionally is compressed so firmly against the sides of the gun that considerable force is required to withdraw the screw, and that as it is impossible to put the steel of the vent plug or obturator face in initial compression in the same way that the rest of the gun is compressed to allow a larger ultimate limit of expansion, it would be necessary to use a very high steel, as the steel ordinarily used is deformed by a pressure of between 30 and 40 tons per square inch. Allowing a factor of safety of two, the steel used for the face of the obturator, or breech screw, would have to be safe at a pressure of 60 tons, and the use of such high steel is not to be advocated at present, as such material is highly treacherous. The objection, that the firing mechanism is damaged or deranged by high pressures no longer exists; whether firing is done either electrically or by percussion, it takes place now-a-days close to the cartridge, and there is no long passage in which a sudden increase of pressure, due to high-velocity gases, can occur. How it comes about that the author has overlooked the advantage that would be gained to the system he advocates by the use of cartridge cases, or cartridge case ends for obturation, we do not know. It seems to us the only feasible way of making the breech secure against leakage; still, it does not get over the difficulty of the pressure on the breech screw, and the necessary doubling in length or diameter of the screw, in order to present enough surface of thread to stand the total pressure. In connection with the temperature of explosion, Mr. Longridge thinks much of the consequent trouble by erosion, &c., due to high temperature, can be avoided by the use of ammonium nitrate powder, of which he gives authority for stating that "the whole charge is probably converted into gaseous matter of comparatively low temperature immediately after the starting of the projectile, and a short gun would be the right thing for it."

There is very much more to be said on this subject which, doubtless, will be said in time, but we feel that we are drawing this review out to too great a length, and will, therefore, conclude with a few of the estimated results from high-pressure guns. If the chamber of 12in. guns now making or made for our new battleships was reduced so as to give a maximum pressure of 27 tons per square inch, using the charge of 148 lb. of cordite, the muzzle energy would be increased from 31,800 foot-tons, as at present, to 42,741 foot-tons; but if the pressure be raised to the same degree by merely increasing the charge to 207 lb. of cordite, the energy becomes 49,032 foot-tons. But the same effect as at present obtained can be produced by using a 10in. gun of about 24 tons weight and 23ft. 6in. total length, with a maximum pressure of 30 tons per square inch, and a sketch of this gun is given in comparison with one of the present 12in guns.

The advantages claimed are that the proposed gun "(1) would be much handier in action; (2) and less vulnerable owing to its less length; (3) it would be loaded and fired more rapidly, since the weight of projectile and charge would be only 634 lb., as against 998 lb. in the case of the 12in. gun; (4) it would cost less than the 12in. gun, in the proportion of 24 to 46"—this conclusion is, as to the weights, very doubtful—"(5) the gun with 100 rounds of ammunition would weigh 52 tons, against 91 tons as in the case of the 12in. gun." It is not improbable, however, that the weight of the carriage would have to be increased, but this is a point with which Mr. Longridge has not dealt at all; yet, nevertheless, the whole of the recoil arrangements for high-pressure guns will need very considerable modification on those at present employed.

In conclusion, we wish to record that, though we have made several observations in disfavour of high pressures, we do not wish it to be supposed that we consider the difficulties by any means insurmountable, and we are entirely in favour of shortening ordnance by whatever means that end may be attained.

Mechanism of Men of War. By R. C. Oldknow, Fleet Engineer, R.N. (Retired). Royal Navy Handbooks. George Bell and Sons, London. 1896.

It is interesting to hear from time to time from members of the Royal Navy opinions of the service, and in the series of volumes edited by Commander C. N. Robinson, R N., of which the present volume forms part, we shall have, when complete, let us hope, a very fair expression of opinion from persons who are intimately connected with the subjects of their respective volumes. The present book would be as good a pill as one could desire to deliver as a corrective to any of those persons who suffer from pessimism with regard to her Majesty's Navy. It is written by a retired fleet engineer, and we may, therefore, take it as worthy of an unguarded reception, except for the allowances which must necessarily be made for a little not unnatural pride, and a large amount of *esprit de corps*. Mr. Oldknow has practically no complaints to make about the Navy. It seems to him, judging only from his book, to be the strongest, the fastest, the best manned, and the best machined Navy in the wide world. This is quite as it should be, from him; from us civilians, who have no practical connection with H.M. ships, a little criticism, a little cold water throwing is, of course, to be expected. Personally, we have never entertained those unhappy opinions with regard to the British Fleet which some people are so fond of vigorously reiterating. Like Mr. Oldknow, we entirely believe her Majesty's Navy not only to be the biggest, but the best that sails the seas; but at the same time we admit there are many faults which need correcting. It cannot be said that it is the best of all possible navies, as the volume before us would lead one to suppose. Probably Mr. Oldknow knows its faults better than we do, and it is only an excess of affection that leads him to view them so leniently that he can say, that breakdowns are practically unknown; greater speeds are obtained after several years' commission than on the official trials; the trouble with boilers is a thing entirely of the past; the steering gear has been practically brought to perfection, and so on, and so on. It is very pleasant reading this sort of thing, even when discounted. and Mr. Oldknow is to be congratulated on having produced a very charming book, written easily and gracefully, and containing a large mass of information served up in a form suitable for the general reader. His is not a technical work, it is a popular account of the propelling and auxiliary mechanism of ships of war, and is written with the object of meeting the wants of the average British subject who takes the interest which is due in the welfare and protection of his country. It is very largely compiled from the contemporary press, standard technical works, and the invaluable publications of the American Intelligence Department, to which all Englishmen go when they want to find any statistics about their own ships of war. The book is well and profusely illustrated with reproductions from photographs and drawings of engines and boilers of all the different types of ships in the Navy. There is nothing essentially new in it, but a good many facts and controversial topics are conveniently collected, as, for example, chiefly in the chapter on the "Battle of the Boilers," in which a candid review of that memorable tussle is brought before us. The book is well printed, contains sixty-one illustrations and some 280 pages, and is sold at the moderate figure of 5s. We can confidently recommend it as easy and interesting reading.

An Elementary Treatise on Rigid Dynamics. By W. J. Loudon, B.A., Demonstrator in Physics in the University of Toronto. New York: Macmillan and Co. 1896. 10s. 6d.

A book of this kind has long been wanted, justifying the Greek motto μηδὲν ἄγαν of the title page, to serve as an introduction, and in most cases, as a supplanter of Dr. Routh's colossal treatise. Professor Pirie has not persevered with his elegant little elementary Lectures on Rigid Dynamics, so that Routh has been left without a rival for many years. The present work is excellent in not following the continental method, which persists in going back to the origin of all dynamical knowledge, so that the reader is halfway through the book before arriving at the real subject. Our author starts with the assumption of the requisite amount of previous foundation, and proceeds at once to the notion of a Moment of Inertia, without which it is impossible to treat the motion of a body which turns as well as advances, like a wheel, or which swings, like a clock pendulum, a bell, or a ship. The part which treats of plane motion, constituting what Maxwell called the gentlemanly knowledge of the subject, is hurried over too rapidly, and the author, in our opinion, is too anxious to get on to motion in space, where the difficulties are nearly trebled. In fact, his main object appears to be the introduction to junior students of the motion of the top or gyrostat, a subject which bristles with analytical difficulties if treated with any pretence of completeness, requiring, as it does, all the various elliptic functions; these elliptic functions are defined in a note at the end of the book.

The only method of obtaining a real grasp of this subject is by working through a number of exercises. The author has carefully ransacked all sources, and has brought together some three or four hundred examples of the most recent type; this forms a most important feature of the book, but the author should have edited away such obscure academic phrases as "tendency to break," "perfectly rough," &c. A word of praise must be added for the diagrams, which are large, bold, and plentiful, and drawn to resemble the objects they are intended to represent.

BOOKS RECEIVED.

Institution of Mechanical Engineers "Proceedings," July, 1895: *Glasgow Meeting.* London, S.W.: Published by the Institution.

Society of Engineers. "Transactions" for 1895 *and General Index,* 1857 *to* 1895. Edited by G. A. Pryce Cuxson, Secretary. London: E. and F. N. Spon. 1896.

Cassell's Natural History. Edited by P. Martin Duncan, M.B. (Lond.), F.R.S., F.G.S. Part I. Price 6d. To be completed in 26 weekly parts. London: Cassell and Co., Ld. 1896.

The Student's Lyell. A Manual of Elementary Geology. Edited by John W. Judd, C.B., LL.D., F.R.S. With a geological map and 736 illustrations in the text. London: John Murray. 1896. Price 9s.

The Application of Graphic Methods to the Design of Structures, Specially Prepared for the use of Engineers. By William W. F. Pullen. Manchester: The Technical Publishing Company, Ld. 1896. Price 6s. net.

Miscellaneous Papers. By Heinrich Hertz. With an Introduction by Professor Philipp Lenard. Authorised English Translation by D. E. Jones, B.Sc., and G. A. Schott, B.A., B.Sc. London: Macmillan and Co., Ld. 1896. Price 10s. net.

Practical Tunnelling. By Frederick Walter Simms, F.G.S., M. Inst. C.E. Fourth Edition, revised and greatly extended, with additional chapters illustrating recent practice. By D. Kinnear Clark. With 36 plates and other illustrations. London: Crosby Lockwood and Son. 1896. Price £2 2s.

Electric Lighting. A Practical Exposition of the Art for the use of Engineers, Students, and Others Interested in the Installation or Operation of Electrical Plants. Volume I.: The Generating Plant. By Francis B. Crocker, E.M., Ph.D. New York: D. van Nostrand Company. London: E. and F. N. Spon. 1896.

Press-working of Metals. A Treatise upon the Principles and Practice of Shaping Metals in Dies by the Action of Presses, together with a Description of the Construction of such Implements in their Various Forms, and of the Materials Worked in them. By Oberlin Smith. Illustrated with 433 engravings. First Edition, First Thousand. New York: John Wiley and Sons. London: Chapman and Hall, Ld. 1896. Price 12s. 6d. net.

SHORT NOTICES.

A Practical Hand-book on the Care and Management of Gas Engines. By G. Lieckfeld, C.E. Authorised translation by G. Richmond, M.E., with instructions for running oil engines. London: E. and F. N. Spon. 1896.—The instructions given in this book with respect to gas engines are based upon the construction and working of the Otto engine, and may thus be taken as pertaining to nearly all the gas engines now made. The man who, on being placed in charge of a gas engine, takes the trouble to read this little book will be the better off, even although 25 per cent. of it is occupied with a description of friction-brake dynamometers and how to use them. These instructions do not, however, refer to the simplest and best brake, and they are wrong in attributing to Professor Brauer the first band brake as now used for dynamometric purposes. The book does, however, present a very well-considered collection of practical suggestions as to the choice of an engine, its examination, power, cost, arrangement of connections, running, and precautions. The chapter on oil engines will not be of much use, as it relates to only one type of engine, and that is one the cycle of which is adopted by only one maker and only partly by one other.

Year-book of the Scientific and Learned Societies of Great Britain and Ireland: Comprising Lists of Papers read during 1895, *before Societies engaged in fourteen departments of research, with the names of their Authors. Compiled from official sources.* Thirteenth annual issue. London: Chas. Griffin and Co. 1896. Price 7s. 6d.—The value of this book has been increased very greatly by the addition of the lists of papers read before the various societies during the previous year. It is not too much to say now, that no one engaged in scientific or literary work can afford to dispense with it. It is one of the most valuable of books of reference.

Compressed Air. Practical Information upon Air Compression and the Transmission and Application of Compressed Air. By Frank Richards, Mem. A.S.M.E. New York: John Wiley and Son. London: Chapman and Hall. 1895.—If this book did no more than renew attention to the use of compressed air as an economical means of power transmission and as an exceedingly useful thing in the workshop and manufactory, it would have served a useful purpose. It does, however, more than this, as in a comparatively simple manner it conveys a great deal of most useful information on air compression, air conveyance, economical and wasteful pumps, and processes and rules and data. It has been written by the author, and bears the impress of originality of treatment. The failure in this country, as at Birmingham, to establish air transmission supply for power and workshop purposes is more to our loss than our credit, and the growing number of successful compressed air supply installations in the States affords some proof of its possible commercial value. Compressed air offers many advantages over any other means of power transmission, the air being useful for so many purposes in the arts, and the possible economy, as Professor Unwin long ago pointed out, is very great. Mr. Richard's book is not only useful from the mechanical point of view, but as drawing attention to the oft quoted and fallacial opinions as to losses attending the use of compressed air, which are not losses at all, but only part of the cost of what is in many respects a very cheap and efficient tool.

INSTITUTION OF ELECTRICAL ENGINEERS.

THE UTILISATION OF WATER POWER, ESPECIALLY WITH A SMALL FALL, WITH SOME EXAMPLES OF PLANTS FOR THE GENERATION OF ELECTRICAL ENERGY.

THE following paper, by Mr. Alph. Steiger, was read at the meeting of the Institution held on Thursday, May 28th.

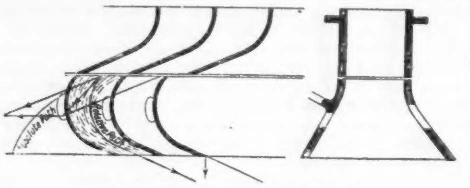

Fig. 1.—Vanes of "Action" Turbine.

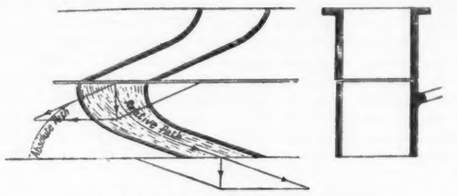

Fig. 2.—Vanes of "Reaction" Turbine.

The cheap production of electrical energy is generally recognised to be one of the chief aims of modern engineering science. Nature has provided us in water power with one of the best possible agents for realising this object; and I trust that, in bringing the subject of the utilisation of this free gift of Nature before the members of the Institution of Electrical Engineers, I shall be able to convince them that the water powers of this country, if judiciously utilised, are capable of rendering them great service. In my own country—Switzerland—the electrical engineer is co-operating cordially with the water power engineer, and electrical installations are rapidly increasing in number. The successful electrical transmission of power to points far distant from its source has been the chief factor in this development. The idea prevails that considerable fall is required to obtain water power, but it is my desire to show and to prove in the following remarks that excellent results are obtainable also with a very low fall—a fall of even less than 3ft. Small falls are more frequently met with in this country than high falls, and will, therefore, have more particular attention in this paper than the high falls found in mountainous districts. The description of a few turbine plants under low falls, some of which are applied to the generation of electrical energy, will be of special interest.

During a long experience in constructing turbines and designing complete plants, I have found that the most difficult were always those connected with the utilisation of a low fall. These difficulties consist chiefly in the variation within very wide limits of both the quantity of water and the fall, while a constant power, and in most cases a constant speed, is of great importance. Generally speaking, the real agent in water power is gravity, and the water is simply the medium to transmit the action of gravity on to the motor which converts it into mechanical work. The action of gravity can take either the form of deadweight, or of pressure, or of velocity, sometines called kinetic energy. A very high efficiency is obtained from motors in which the water acts by deadweight or by pressure, but the slow speed of the water-wheels and the complicated mechanism of the pressure engines render them unsuitable for the purpose of generating electricity; moreover, motors worked by weight or by pressure are only advantageous when working under a high fall. The kinetic energy is the only form in which the gravity can be applied advantageously to the performance of mechanical work under a small fall. The motors using it in this form are the common undershot wheel, the Poncelet water-wheel, and the turbines.

It will be sufficient for the purpose of this paper to give the efficiency of the various types of water motors for any fall, without going into a detailed description of those which are unsuitable for driving dynamos. The efficiency of the motors, with the fall for which they are adapted, is as follows:—

Fall. Feet.	Efficiency of water-wheel.	Per cent.	Efficiency of Turbine. Per cent.
1 to 5 ..	Ordinary undershot ..	25 to 30	.. 70 to 75
	Poncelet	65 to 70	
	Sagebien	65 to 75	
5 to 8 ..	Low breast	30 to 50	.. 75 to 80
8 to 15 ..	High breast	60 to 75	.. 75 to 80
15 to 50 ..	Overshot wheel	65 to 75	.. 75 to 80
Above 50 ..	Pressure engine ..	75 to 85	.. 75 to 80

These figures show the interesting fact that, the smaller the fall is the greater is the gain in power over the old-fashioned water-wheels. Although the smallest fall which would reasonably be utilised by a turbine is at least 2ft. 6in., I will show by some examples that, by a turbine suitably constructed and carefully adapted, useful power is still obtained under a fall of only 1ft. or a little over. The great variety of fall, water supply, local conditions, and special requirements, of necessity demands a variety of types of turbines.

Turbines are classified, according to the manner in which the water acts in them, into (*a*) "impulse" or "action" turbines, and (*b*) "reaction" turbines; and according to their construction, into (*a*) parallel flow turbines; (*b*) radial flow turbines; (*c*) mixed flow turbines. There is an essential difference between the "impulse" turbine and the "reaction" turbine, as indicated by the form of vanes illustrated in the diagrams Figs. 1 and 2.

The "impulse" turbine, as usually constructed, must run clear of the tail water, its buckets being only partially filled with water. It requires a constant fall, with constant level of the water in the head and tail race, but its efficiency is not affected by the greatest variation of the water supply. On account of this quality, it can be built as partial injection turbine, to utilise high falls with a very

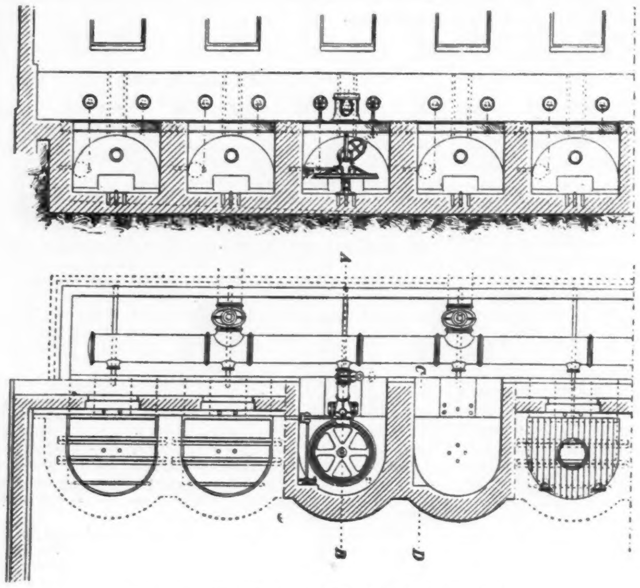

Fig 3 a.—Turbines at the Falls of Foyers, Scotland.

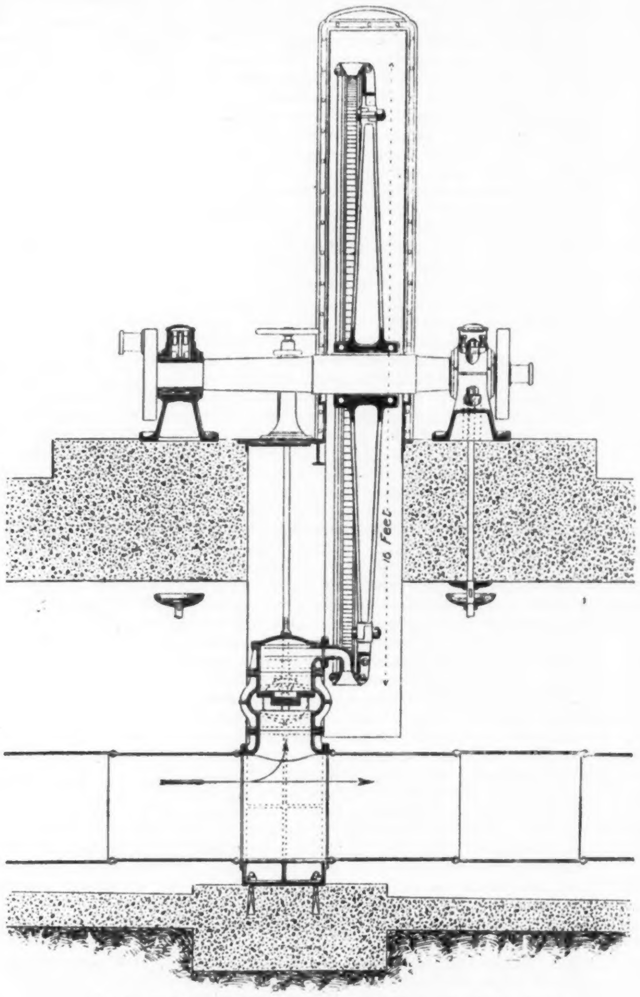

Fig. 4.—Turbines of the Chauxdefonds Waterworks Switzerland.

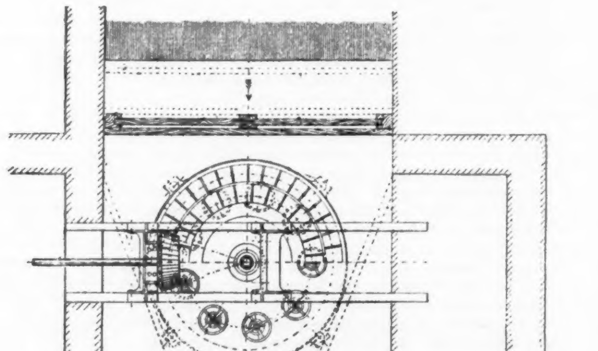

Fig. 5 b.—Turbine at Brantham Mills, Essex—Ground Plan.

small water supply. If constructed as "partial injection turbine," its diameter can be chosen so as to give just the desired number of revolutions. This is extremely convenient for driving dynamos, which can thus be connected direct with the shaft of the turbine, doing away with intermediate gearing or belt drives. An instance of this kind is the turbine plant now being erected by Messrs. Escher, Wyss, and Co., of Zurich, at the Falls of Foyers, for the British Aluminium Company. This plant consists of five "impulse" turbines with vertical shaft, with partial injection, each giving 700 brake horse-power, working under a fall of 350ft. The dynamos are required to run at 140 revolutions per minute, and to obtain this speed the turbines were given a diameter of a little over 9ft. Partial injection turbines under a high fall are sometimes fixed on a horizontal shaft, and can thus be coupled direct to the armature spindle of a dynamo by means of an isolating coupling. This mode has been adopted, amongst numerous other plants, for the electric lighting installation of Davos, in Switzerland, which consists of three horizontal patent turbines of 200 brake horse-power each, working under a fall of 330ft., and running at 400 revolutions per minute. The turbines have a diameter of 40in. As a contrast to these turbines of large power and small diameter, and to show the adaptability of the partial injection turbine to special requirements, the 140-horse power turbines of the waterworks in Chauxdefonds may be mentioned. These work under a fall of only 170ft., but as they are driving pumps at the low speed of 60 revolutions, they had to be made of a diameter of 15ft. Great as the advantages of the "impulse" turbines are under the conditions above mentioned, their use under very low falls is limited, firstly, owing to the reason already given that they must run clear of the tail water—a condition which can seldom be realised in a flat country like this; and, secondly, because they run at a slower speed than a "reaction" turbine under the same fall. Although "impulse" turbines are now built to run in the tail water without considerable loss of efficiency, the reduction of power in proportion to the reduced fall, and the quantity of water accordingly reduced, together with the reduced speed, excludes them in the majority of low and varying falls.

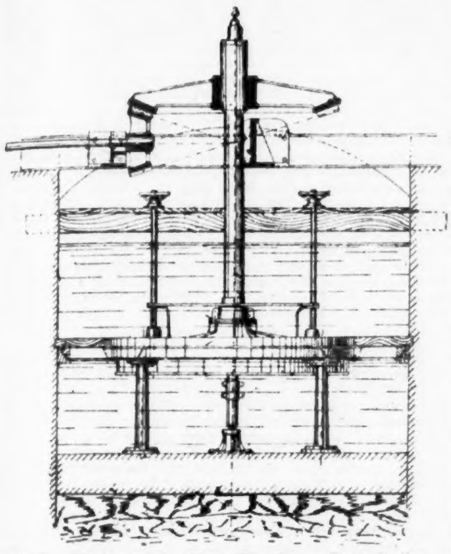

Fig. 5 a.—Turbine at Brantham Mills, Essex—Cross Section.

The ideal turbines for low and varying falls are the "reaction" turbines. They are generally placed in a level with the tail water, or, if local conditions require them to be placed above tail water, connected with it by a suction tube. They run at a higher speed for the same fall, or the same diameter, than an "impulse" turbine, and their efficiency is not affected by the immersion in the tail water. The principal objection raised against "reaction" turbines in general is that their efficiency is greatly reduced when working at part gate. This is, indeed, the case with many of the reaction turbines known in this country, which give a very poor efficiency at part gate, especially at less than half gate. The continuity of flow of the water through the buckets is essential to a good efficiency. Only in a few reaction turbines is this condition fulfilled to such an extent that within very wide limits of the water supply the efficiency is not perceptibly reduced. The utilisation of a small and varying fall, with a varying quantity of water, is a very difficult problem for the water-power engineer. The turbine for a given power under a low fall is larger and runs slower than one of the same power under a higher fall; it is, therefore, heavier and more costly, and requires heavier gearing, entailing a greater loss of power through friction. A high speed is desirable, especially for driving dynamos; but attempts to increase the speed of the turbine by reducing its diameter may easily result in an inferior efficiency. The efficiency should be as high as possible in consideration of the greater cost of a water-power plant with a low fall; but the proportions within which such a fall and the quantity of water varies is mostly so great that it is almost impossible to obtain the highest efficiency when the water supply is diminished, *i.e.*, when a high efficiency is most wanted. The maintenance of a constant power with a constant speed under variation of fall and quantity of water in large proportion can, if at all, only be attained by sacrificing some efficiency. The hydraulic losses must be reduced to a minimum by the most careful construction of the turbine in its essential parts, and it is needless to say that no standard size or type of turbine will fulfil all these conditions by simply consuming all the available water.

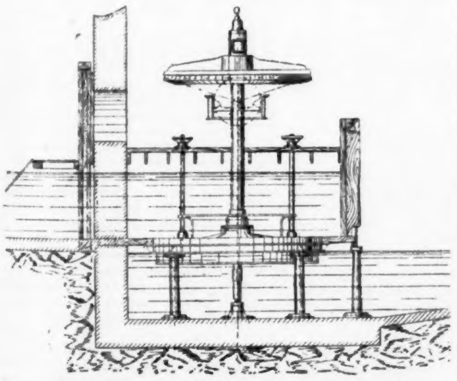

Fig. 5 c.—Turbine at Brantham Mills, Essex—Longitudinal Section

Even the arrangement of the turbine chamber is of influence on the results, and requires special attention. On a careful judgment of the local conditions depend the economy and the success of a plant. Unsatisfactory results in water power plants are caused just as much, or oftener, by bad judgment of the local conditions than by the inferiority of the turbine. In by far the most cases of low falls, incidental to flat countries, an abundance of water corresponds with a reduction of the fall. The power of a turbine calculated for the normal fall would be reduced, for the time, when an abundance of water reduces it, and, as a consequence, water would be wasted, while the power obtained is insufficient. These cases are, unfortunately, of frequent occurrence. On the other hand, if the turbine is constructed to give off the required power under the reduced fall, it must be partially closed for the diminished water supply with the normal fall, whereby the efficiency would be reduced just when it should be highest if economy is at all the chief object of a turbine plant.

The manner in which a high efficiency can be maintained for a diminished water supply is to subdivide the turbine into several compartments, each of which represents a complete turbine. This arrangement has been adopted by Fourneyron for his well-known outward flow turbine, and in the modern Jonval turbine. The Fourneyron turbine is provided with a cylindrical gate, which is moved vertically, whereby each compartment is opened or closed. This type has been adopted for the large-power plant on the Niagara Falls, but on the European Continent they are seldom used. Their efficiency is very good, but, owing to the narrowness of the buckets, they are easily choked. The Jonval turbine is a parallel flow turbine, and is, for large variations of the fall and quantity of water, subdivided into two or more concentric compartments. A subdivision in this manner renders it possible to maintain not only the power, but also the speed, under a varying fall within very wide limits.

The description of a Jonval turbine installation which I supplied for the Brantham Mills, near Manningtree, in Essex, here illustrated, will show that a very small and varying fall can be utilised with great advantage to obtain nearly a constant power. The local conditions and requirements are most remarkable and interesting. The power is used to drive a modern flour mill, in which the maintenance of a regular speed is of equally great importance as for driving an electrical plant. The river Stour is a tidal river, with a maximum fall at ebb tide of 4ft. 10in., while at high tide the fall is nil. The water is supplied partly by the river itself coming down from the hills of Cambridgeshire, and partly by the rising tide filling the river bed above the mill for a considerable length. The power required is 40 actual horse-power, and it was stipulated that this power should be maintained down to a fall of 40in. On starting the turbine, it was shown, however, that it drove the mill at full capacity and at full speed under a fall reduced to 32in. The full power is available during sixteen hours of each day, while during six further hours the power corresponding to a fall reduced down to about 1ft. is still utilised for driving a part of the machinery. Comparing the useful power obtained from this varying fall by the new turbine during twenty-four hours with that obtained by the undershot water wheel previously working, it is nearly six times larger. The turbine consists of only two concentric rows of buckets; the inner one is provided with gates, which are opened or closed by hand wheels, an automatic governor not being generally used in flour mills. The outer row of buckets is just large enough to give the full power required under the maximum fall. As the fall is decreasing by the rising tide, the gates of the inner row of buckets are gradually opened to make up the power by an increased quantity of water, and the more water is passing through the buckets of the inner row the more it acts on a reduced mean diameter, thus maintaining also the proper speed without perceptible loss of efficiency.[*] The power is transmitted from the turbine on to a horizontal main shaft by means of a pair of bevel wheels. This horizontal shaft is made to run at 75 revolutions, and is provided with a clutch by means of which the turbine is connected with the steam engine if the mill is required to work continuously. When the fall is reduced to more than 32in., the mill is, however, driven separately by the steam engine, and the power of the turbine is used to drive the wheat-cleaning machinery, and eventually some pairs of millstones which can work independent of the automatic roller mill plant. When the fall is reduced to 15in., the power that is still obtained from this turbine is 7-horse power, the turbine naturally running slower; but still this power is quite sufficient to be profitably utilised.

(*To be continued.*)

HORSELESS CARRIAGE NOTES.

WE learn from our American correspondent that the State Fair Association of Rhode Island has decided to arrange for a series of races of horseless vehicles as well as of horses, at the State Fair, which will be held at Providence in September. It is expected that a large number of the carriages will be exhibited and entered for the races, and the Association has offered £1000 in prizes.

SINCE our issue of the 15th inst., when we published the regulations for the competitive trials for the four prizes, two of £100 and two of £50, offered by the Royal Agricultural Society in connection with its Manchester meeting next year, the regulations have been separately issued by the Society. They are as published on page 497 *ante*, with the addition that the entries for these prizes must be made on or before Thursday, 1st April, 1897, and must be accompanied by a deposit of £10 for each entry, the deposit to be forfeited if the "machine" is not submitted for competition at the time appointed for the trials. It will be noted that the Society only stipulates as to weights; that of the loads to be carried are either a maximum of two tons or of five tons, but the weight of the vehicle is to be considered by the judges. Nothing is said as to the passage of the Bill at present before the House of Commons; this is taken as a matter of course.

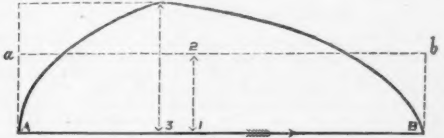
WRITING from Clifton Park, Kelso, N.B., on a defect in the Horseless Carriage Bill, as relating to Scotland, Mr. T. R. B. Elliott says:—"As an owner of a horseless carriage, and being much interested—in no way financially—in the new movement, I trust you will allow me to draw the attention of the Scottish members of Parliament and of the Scottish people in general to a serious defect, as far as Scotland is concerned, in the Locomotives on Highways Bill, which has recently been read a second time in the Lords, and which, if it becomes law, will allow England to avail herself of an easy, cheap, and safe form of road locomotion, practically free from restriction, while Scotland and Ireland will be so hampered by local regulations that they will be quite out of the field. The Bill now before the House, says, 'Section 25 (c), so much of Section 6 of the Locomotives Amendment (Scotland) Act, 1878, and of Section 6 of the Public Health (Ireland) Amendment Act, 1879, as gives power to regulate the use of locomotives, shall apply to light locomotives—*i.e.*, horseless carriages—under two tons." The section referred to in the Act of 1878 runs as follows:—'Be it enacted that the road authority of any county or burgh may make byelaws as to the hours during which locomotives are not to pass over the highways situated within the areas respectively above-mentioned, the hours being in all cases consecutive hours, and no more than eight out of the twenty-four, and for regulating the use of locomotives upon any highway, or preventing or regulating such use upon every bridge, where such authority is satisfied that such use would be attended with damage to the public from the narrowness, inclination, or imperfect construction of such highway or bridge respectively.' Thus, while in England a horseless carriage will be able to go anywhere unmolested, in Scotland and Ireland its owner will be at the mercy of every local authority, everyone of whom will have different opinions on the subject; and as a horseless carriage does not tire, it will be impossible to go 100 miles in any direction in Scotland without being stopped by some local regulations as to hours, roads, bridges, &c. The new limit of weight ought not to be too much for any bridge over which heavily-laden carts are allowed to pass, and as to hours and roads, it may interest sceptics to know that I have recently completed 740 miles, chiefly in Scotland, on almost all kinds of roads, narrow and otherwise, and also at all hours, and I have never caused an accident of any kind. Why, then, should Scotland be handicapped in this way, and England given a free hand in this new venture? It is not fair play, and the only remedy is for those interested in Scotland to approach their members, with a view to having an amendment made to this one-sided Bill before it is too late; and, if this amendment is opposed, why, then, let Scotland and Ireland oppose the whole Bill, for it is of no use to any of the three kingdoms—except England—in its present form." This is further evidence of the necessity for freeing the Bill as far as possible from all restrictions that do not pertain to all ordinary vehicles.

A RAPID TRANSIT PROBLEM.

THE following, by G. Leverich, is from the *Railroad Gazette*:—

Given two stations A and B, on a level, straight railroad track, separated by a space S—required, in what time a train starting at A and stopping at B, may traverse this space.

In a diagram, A and B are the stations; the space between them is S, and A 4 B are curves indicating the speed between these stations, A 4 the acceleration from A the starting point, and 4 B the retardation to the stopping point; hence the normal 3, 4, from the intersection of these curves 4, to the base S, represents the maximum speed attained. Also the area of the parallelogram A*a*, *b*B, equal to the area enclosed by the two curves and the base S, divided by the base S, namely 1, 2, represents the mean speed attained.



It will be noticed that the retardation curve is practically constant—its elements being determined by the conditions of stopping a train safely and without inconvenience to passengers: the acceleration curve, if similar conditions are disregarded, may range from A B, representing no speed, to A5, representing infinite speed. Should the latter be possible—that is, the train at starting, immediately move at maximum speed—the increase of mean speed between the two stations, over that represented by 1, 2, in the diagram, would only be that represented by area A4, 5, *a*, divided by the space S—quite small as compared with area A*a* *b*B divided by the same space.

Simple formulæ indicate the trend of these two curves—acceleration and retardation, and consequently the maximum and mean speeds possible—the constants in each formulæ being determined by the operation of trains, subject to conditions similar to those under consideration.

As perhaps is reasonable—and surely tending to the reduction of time of transit—it has been assumed that the acceleratien of speed may be thrice the retardation; that is, a train leaving a station may acquire maximum speed in one-third the space between that station and the one at which it is to stop. Also it is assumed that the trains shall stop one minute at each station.

From the formulæ and subject to the conditions mentioned, the following table has been computed, showing the spaces required between stations, that trains may be moved at the speeds indicated:—

Speed—Miles per hour.			Between stations.	
Mean.		Maximum.	Space—Miles.	Time.
Over the entire line.	Between stations.			
				hrs. min.
5	12·2	18·2	0·14	1 42
10	19·1	28·6	0·35	2 6
15	25·3	38·	0·61	2 27
20	31·2	46·7	0·93	2 48
25	36·8	55·2	1·3	3 7
30	42·3	63·5	1·72	3 26
35	47·7	71·6	2·18	3 44
40	53·1	79·6	2·7	4 3
45	58·4	87·6	3·27	4 22
50	63·7	95·5	3·89	4 40
55	68·9	103·3	4·55	4 58
60	74·	111·1	5·26	5 16

From this it appears that, for a mean speed over the entire line of 15 miles per hour, the maximum speed between stations shall be 38 miles, and these stations shall be nearly five-eighths of a mile apart; that for a mean speed of 30 miles the maximum speed shall be 63½ miles, and these stations shall be nearly 1¾ miles apart, and that for a mean speed of 45 miles the maximum speed shall be nearly 88 miles and the stations shall be over 3¼ miles apart.

WILLANS AND ROBINSON, LIMITED.—It will be seen from our advertising pages that Messrs. Willans and Robinson, Limited, are issuing £100,000 worth of debenture stock, for the purpose of completing the company's works at Rugby, wherein the manufacture of the Niclausse water-tube boiler will be carried on.

NAVAL ENGINEER APPOINTMENTS.—The following appointments have been made at the Admiralty:—Chief engineer: Samuel Aston, to the Scylla, to date May 28th. Engineers: W. H. W. Stewart, to the Vivid, for the Opossum; Joseph N. Crowle, to the Vivid, for the Shark; B. J. Watkins, to the Vivid, for the Rocket; E. W. Rodet, to the Victory, for the Hart; J. G. Liversidge, to the Wildfire, for the Snapper; T. S. Guyer, to the Victory, for the Starfish, to date May 7th; and Henry E. Tregenna, to the Scylla, to date May 28th. Assistant-engineers: Edward J. Rosevere, to the Bellona, and George H. Fletcher, temporary, to the Scylla, to date May 28th.

---

[*] The outside diameter of this turbine is about 10ft., and it runs with 24 revolutions per minute.

LETTERS TO THE EDITOR.

(*Continued from page* 539.)

UNDERGROUND STEAM PIPING AND INSULATING.

SIR,—I was much pleased to see in your issue of February 21st a full report, with drawings, of a paper read by R. C. Carpenter, at the annual meeting of the Society of Heating and Ventilating Engineers of New York. I think, Sir, you will agree with me in saying that the work, as carried out according to those drawings, can be much improved upon. I enclose a rough tracing of a plan which I tried to bring out in 1874, which I named the universal steam supply. My idea did not meet with favour when submitted to one or two gentlemen of distinction. It was said to be of too great magnitude, and too far ahead of the times. The Americans, under the guidance of Mr. Holley, soon after this commenced the system of laying down services of steam supplies on a large scale. It has been a great wonder to me that no steps have been taken to adopt the system in London or other large towns. To my thinking London especially should have an underground steam supply. It would minimise the fog nuisance by supplying heat to thousands of houses which now have to use open fires, by taking steam into your house from the street mains, and using it for culinary purposes first, and then let it ascend through pipes and radiators to all rooms in the house, or any special room as required. What a great benefit it would be in winter. Imagine the pleasure of having the whole of your house kept at one uniform heat in winter. There are numbers of warehouses and places in and about the City which would readily use steam for heating purposes, and at no extra rate for fire insurance. On the other hand, steam as an extinguisher of fire is equal, if not superior, to water. Take, for instance, a warehouse fitted up with a steam service, and should a fire occur in any particular room, it would only be necessary to open an outlet tap and shut the door; the steam would choke out the fire without flooding the place as with water. The uses to which steam can be applied are many—for driving engines in small workshops, for hoists, &c.; the exhaust steam, after being used by the engine, is sufficient to warm a large area of space. The only care in fitting up an exhaust system is to have the pipes of ample size, so as not to cause back pressure on the engine. Hotels, restaurants, coffee-houses, would find a steam supply of inestimable benefit, and at no risk of fire, as at present with gas. My plan is also to have plugs in the streets, for the purpose of melting away snow and supplying steam to fire engines. Some people run away with the idea that by loss of heat by radiation the steam would lose its effect. I contend, by having the pipes laid in a suitable trench, and properly covered or insulated, and the boilers at suitable distances apart, so that the steam is always circulating from one boiler to another, the system is thoroughly practical. I think, Sir, a little fair discussion in your valuable paper upon the merits or demerits of this subject would benefit the community at large.

H. GRAY, Engineer.

Alten-road, Auckland, N.Z., April 15th.

MR. BAYARD AND H.M.S. CALLIOPE.

SIR,—I beg to be permitted to record and to refer to the remarks a few days ago of the American Ambassador, who, in a very interesting speech and graceful reference, said: "A while ago, in a very remote part of the world, there was a great catastrophe. Away down in Polynesia there came a tornado in the Samoan Islands. A cyclone swept the armed ships of three nations into destruction. The Americans were lost, and part of the British were lost; Germany was stranded, and one ship alone survived the disaster. It was a British ship, the Calliope, commanded by an honest, brave British seaman, Captain Kane. He fought the tempest, and inch by inch gained his way against it."

May I be once more permitted to remind your readers that the Calliope—2770 tons, 4020-horse power—was fitted at the time with a two-bladed "feathering" propeller with movable blades, for the purpose of placing the said blades in a line with the keel, to save resistance when sailing. The fact that such a screw carried her to safety out to sea establishes beyond a doubt the sufficiency and safety of outboard movable blade holding gear. I may add to this the many and long-continued trials during the last five years, and under all conditions, of reversing screws, gears, and direct-acting system and attachments operated while running by non-reversing engines, thus proving that the great advantages of non-reversing engines and reversing propellers are attained without any disadvantages.

ROBERT MCGLASSON.

Selhurst, S.E., May 16th.

THE JOULE EFFECT.

SIR,—In connection with the interesting correspondence on the liquefaction of gases, which is being carried on in your columns, perhaps the following short account of Joule and Thomson's experiments "On the Thermal Effects of Fluids in Motion," by which the existence of what is now know as the "Joule effect" was indicated, may be acceptable.

In a communication to the British Association in September, 1852, Joule and Kelvin gave an account of certain preliminary experiments they had jointly carried out earlier in the same year. The object of these experiments was to test Mayer's hypothesis, by which he obtained a numerical relation between quantities of heat and mechanical work. This hypothesis had been adopted by Clausius, Holtzman, and others, and had been verified as at least approximately true by Joule, for air at ordinary temperatures. But Kelvin, in his mathematical investigations on the dynamical theory of heat, &c., arrived at conclusions which led him to doubt the accuracy of the hypothesis. Mayer's hypothesis is briefly this: The heat evolved from air compressed, and kept at a constant temperature, is mechanically equivalent to the work spent in effecting the compression.

The principle of the method employed to test this hypothesis is given by the authors in the following words:—"Let air be forced continuously and as uniformly as possible, by means of a forcing pump, through a long tube open to the atmosphere at the far end, and merely stopped in one place, so as to leave for a short space only an extremely narrow passage, on each side of which, and in every other part of the tube, the passage is comparatively very wide; and let us suppose, first, that the air in rushing through the narrow passage is not allowed to gain any heat from, nor—if it had any tendency to do so—to part with any to the surrounding matter. Then, if Mayer's hypothesis were true, the air, after leaving the narrow passage, would have exactly the same temperature as it had before reaching it. If, on the contrary, the air experiences either a cooling or a heating effect in the circumstances, we may infer that the heat produced by the fluid friction in the rapids, or, which is the same, the thermal equivalent of the work done by the air in expanding from its state of high pressure on one side of the narrow passage to the state of atmospheric pressure which it has after passing the rapids, is in one case less, and in the other more than sufficient to compensate the cold due to expansion; and the hypothesis in question would be disproved" (*Phil. Mag.*, 1852, page 482).

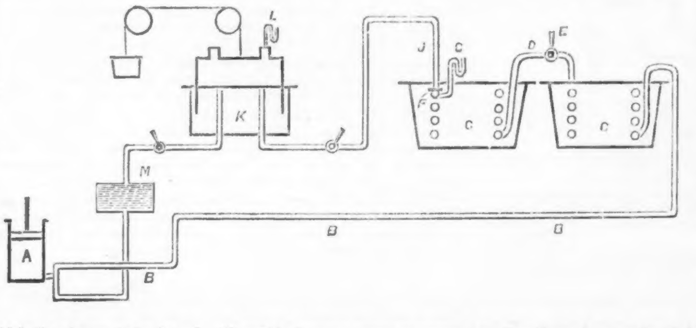
The apparatus employed consisted of a hand forcing pump adapted to pump air into a strong copper vessel of 136 cubic inches capacity, used for the purpose of equalising the pressure of the air, and from this into a spiral leaden pipe 24ft. long and $\frac{5}{16}$in. in diameter, provided with a stop-cock at its other end, the spiral being immersed in a large water bath during the experiments.

The water of the bath was kept at a uniform temperature throughout by constant stirring. In the first series of experiments the narrow orifice was made by simply nearly closing the stop-cock. Afterwards, in another set of experiments, the narrow passage was formed by fixing a narrow india-rubber tube to the stop-cock, which was kept fully open, and squeezing the end of the tube with a pair of wooden pincers. This change was made to diminish the effect arising from the conduction of heat through the metal of the stop-cock. It was found in both cases that, the pump being worked uniformly, a thermometer placed in the current of air flowing from the narrow passage showed a lower temperature than the air on the other side, which was assumed to be the same as that of the bath in which the spiral was immersed. The temperature of the bath was kept in the first series of experiments as nearly as possible the same as that of the surrounding atmosphere. In the second series, in addition, the effect of increasing the temperature of the bath to 150 deg. Fah. was tried. A cooling effect was still obtained, though the amount was less in this case than when the temperature of the bath was lower. The pressures were made to vary during these experiments from two to five atmospheres. The authors next attempted to determine the whole thermal effect by means of a calorimetrical apparatus applied externally, for it was considered possible that the observed cooling of the air might be due wholly or partly to its reaching the thermometer bulb before it had lost all the *vis viva* produced by the expansion in the narrow passage, and consequently before the full equivalent of heat had been produced by the friction. It is, however, unnecessary to give an account of these experiments, as the results were not very conclusive; though, on the whole, the authors considered that a cooling effect due to the air rushing through the narrow passage was indicated, if not satisfactorily proved.

After the completion of these experiments by Joule and Kelvin, the former made some additional ones to obtain a decisive test of the discrepancy from Mayer's hypothesis indicated by the experiments already described, and to determine its amount for different temperatures. For this purpose he soldered a piece of brass piping to the end of the leaden spiral, and having fastened a piece of calf-skin leather over its mouth, found that the natural pores of the leather were sufficient to allow a uniform and conveniently rapid flow of air from the receiver. The end, over which the leather diaphragm was bound, was protected with a vulcanised india-rubber tube, so that it could be immersed in the water bath to a depth of about 2in. A small thermometer was placed within this tube, the bulb being allowed, for convenience, to rest on the centre part of the leather diaphragm. It was ascertained that the effects were not perceptibly diminished when the thermometer was raised a quarter of an inch above the diaphragm. This was the first introduction of a porous plug into the experiments, and it was this apparatus that was used two years afterwards by Joule and Kelvin in their experiments with hydrogen. On this occasion—1852—during the first series of experiments, the temperature of the bath was kept at 61 deg. Fah., and pressures varying from 1·79 to 4·11 atmospheres were employed. The observed cooling effect was 0·5 deg. Fah. with the lower pressure, and 1·7 deg. Fah. with the higher pressure.

In the second series, consisting of six different experiments, the bath was kept at a temperature of 160 deg. Fah., and the pressure at 2·64 atmospheres, the cooling effect varied from 0·264 deg. to 0·66 deg. Fah. The variation being considered as probably due to alterations in the copiousness of the stream of air in passing through the plug—for, the more copious the stream the less of the cooling effect would be lost by conduction of heat from without—in all the subsequent experiments the quantity of air pumped through per second was observed. In the first five experiments of the third series 5·6 cubic inches of air were pumped through per second, and in the next two 8·4 cubic inches; the temperature of the bath was 170·8 deg. Fah. In three of these experiments the pressures were 4·11 atmospheres, and the cooling effects were 0·528 deg., 0·66 deg., and 0·726 deg. Fah. In all the subsequent experiments similar discrepancies occurred; due, in the opinion of the authors, to the want of a sufficiently copious current, showing, they state, how much uncertainty there must be in the results on account of purely accidental circumstances. But they consider it is perfectly established that there is a final cooling effect produced by air rushing through a small aperture at any temperature up to 170 deg. Fah., and that the amount of this cooling effect decreases as the temperature is augmented.

With the aid of a grant from the Royal Society, Joule and Kelvin carried out in the following year experiments on a far larger scale; a full account of which is given in the *Phil. Trans.* of the Royal Society for 1853. The accompanying figure, roughly copied from a drawing given in the report above referred to, will give a sufficient idea of the apparatus employed. It consisted of a single-acting pump *a*, worked by a steam engine. The pump cylinder was 6in. in diameter, and the stroke of the piston 22in. The air entered at the bottom of the cylinder during the up stroke and was expelled into the receiving tubes on the down stroke. The number of strokes per minute was limited by the governor of the steam engine to twenty-seven. Both the cylinder and valves of the pump were immersed in water. Forty-seven feet of wrought iron tubing *b b b*, of 2in. internal diameter, conducted the compressed air to the coils *c c* of copper tubing immersed in two wooden tubs filled with water. The copper tubing was of the same internal diameter as the iron, and had a total length of 74ft. A stop-cock *e* was placed between the coils, with the object of letting a portion of the air escape when it was wanted to reduce the pressure. The terminal coil had a flange *f*, to which could be attached any required nozzle containing the porous plug through which the air was to be forced. Near this flange a mercury gauge *g* was placed to indicate the pressure. A pipe *j* conveyed the air issuing from the nozzle to a calibrated gas meter *k*, having a capacity of 40 cubic feet. A pressure gauge *l* connected with the meter indicated any slight difference that might exist between the pressure in the meter and the external atmosphere. From the meter the air could be made to pass through a desiccating apparatus *m*, and thence to the pump, so as to circulate through the entire apparatus. In addition to the above it was found necessary during the course of the experiments to prevent the considerable oscillations in pressure due to the action of the pump, to place a diaphragm of copper, pierced with a hole ¼in. in diameter at the junction between the iron and copper pipes. With this addition to the apparatus the oscillations in pressure were hardly perceptible. To prevent any of the lubricating oil from the pump being carried to the porous plug at the far end of the copper coils, a box with perforated cups filled with cotton-wool was afterwards substituted for the copper diaphragm, which was equally effective in keeping the pressure uniform. The porous plug used for these experiments was composed of 251 grs. of cotton compressed into a space 1½in. in diameter and 1·9in. long. It was contained in a metal cylinder with flange to bolt to the end of the copper tube. Contact between the metal and cotton-wool plug was prevented by a piece of india-rubber tubing.



It is unnecessary to give the entire tabulated accounts of the experiments made under the different conditions above described. The following table gives the mean results of the last four observations in each series:—

Series.	Pressure in lb. on the sq. in.	Atmospheric pressure.	Temperature of bath. Fah.	Temperature of issuing air. Fah.	Cubic inches of air passing each minute reduced to atmospheric pressure.	Cooling effect. Deg.
			Deg.	Deg.		
1. Without diaphragm	35·866	14·695	65·0381	64·4198	12,703	0·6183
2. With diaphragm ..	35·9	14·755	66·5636	65·937	11,796	0·626
3. With box	34·279	14·71	58·2926	57·7328	11,784	0·5598

Finally, a number of experiments were made with reduced pressures, obtained by partially opening the stop-cock *e* between the coils, and thus permitting some of the air to escape into the surrounding atmosphere, and consequently diminishing the quantity arriving at the nozzle. The results obtained on this occasion were apparently anomalous, and need not be given here.

In a communication to the Royal Society in the following year—*Phil. Trans.*, 1854, page 321—Joule and Kelvin gave an account of a series of very elaborate and most interesting experiments by which, in the first place, they were able to account for the apparently anomalous results obtained under the conditions above referred to. It was shown that these were due to considerable fluctuations in temperature, occasioned by the sudden opening or closing of the stop-cock *e*—see Fig. The cause of these fluctuations, which continued for a considerable time, was explained, and it was found that the only precaution required to prevent their injurious effect on the accuracy of the results was simply to keep the action of the pump as uniform as possible, and only to commence the record of the experiments after the fluctuations had died away, viz., from an hour and a-half to two hours after the starting of the pump. The nozzle containing the porous plug used during these experiments was made of boxwood instead of brass, and was placed in a tin can filled with cotton-wool to keep the water of the bath from coming in contact with the wood.

In the first set of experiments made on this occasion the cotton-wool plug weighed 191 grains. The quantity of air passed through the nozzle varied from 10,998 to 10,769 cubic inches per minute. The mean results were as follows:—

Pressure in pounds on the square inch	20·969
Atmospheric pressure	14·624
Temperature of bath, Fah.	62·6108 deg.
Temperature of the issuing air	62·4164 deg.
Cooling effect	0·1944 deg.

Under almost precisely the same conditions as regards pressure and temperature in Series 7 of the preliminary experiments with a hand pump, the mean cooling effect was found to be 0·42 deg. (*Phil. Mag.* 1852, page 489) a result apparently exactly contrary to that anticipated by the authors, who considered that in these preliminary experiments, "very much of the cooling effect must be lost on account of the insufficiency of the current of air" (*Phil. Mag.* 1852, page 490).

In the next series of experiments a cotton-wool plug of 382 grains was used, and the stop-cock was kept partially open so that the pressures might not widely differ from those in the above series. The quantities of air passing through the nozzle on three occasions when they were observed, were 3865, 3960, and 3125 cubic inches per minute, and the mean results were:—

Pressure in pounds on the square inch	22·678
Atmospheric pressure	14·540
Temperature of bath Fah.	68·225 deg.
Temperature of issuing air	67·9842 deg.
Cooling effect	0·2408 deg.

In the next series the entire quantity of air propelled by the pump, which amounted to 11,766 cubic inches a minute, was passed through the plug, the mean results being:—

Pressure in pounds on the square inch	35·993
Atmospheric pressure	14·577
Temperature of bath Fah.	63 9892 deg.
Temperature of issuing air	63·302 deg.
Cooling effect	0·6372

For the sake of comparison the following mean results of Series 8 of the preliminary experiments are given below (*Phil. Mag.* 1852, page 490):

Quantity of air in cubic inches passing through the plug.	Temperature of bath Fah.	Pressure of air in atmospheres.	Cooling effect.
168	deg. 64·48	2·41 about 35·4 lb. on the square inch	deg. 0·56

Afterwards a number of similar experiments were made with silk instead of cotton plugs, the results of which were in accordance with those already given. The effect on carbonic acid and on hydrogen was also determined; it was much greater than air with the former, and only one-thirteenth of the cooling effect observed with common air with the latter. The apparatus employed on this occasion in the experiments with hydrogen was the small one used in the preliminary experiments. In experimenting some years later on a larger scale with hydrogen, a heating instead of a cooling effect was obtained (*Phil. Trans.*, 1862.) On this occasion, for the convenience of experimenting with hydrogen, and other gases not so easily procurable in large quantities as air or carbonic acid, a porous plug of smaller dimensions, enclosed in a nozzle of less capacity for heat, was used. A smaller air pump was also used, but it was a double instead of a single-acting one.

It is impossible to read the original accounts given by Joule and Kelvin of their experiments, without being struck by the remarkable skill, patience, and inventive resources they displayed during their investigations. But I must admit that it appears to me not a little remarkable—considering that the express object of the investigation was to determine whether the gas experimented with was at different temperatures on opposite sides of the porous plug—that it seems never to have occurred to the experimentalists to settle this matter beyond question by testing the temperature of the gas on both sides of the plug with thermometers—a not very difficult operation, one would suppose—instead of assuming that the gas on the high-pressure side of the plug was at the same temperature as the bath in which the copper coil containing it was immersed. It seems to me that this might very well not have been the case, for the following reason. Each time the valve between the pump and coil was closed, the gas in the pipes would continue to be forced through the porous plug by expansion only. Obviously, as work is being done, a cooling effect on the gas within the coil would take place. This cooling effect would be modified by two causes:—(1) By the heat conducted inwards from the bath; and (2) by the heat due to compression each time a fresh supply of gas was forced into the pipes by the action of the pump. Regarding this second action, Joule and Kelvin state in their report (*Phil. Trans.*, 1853, page 363):—"There was also another source of interference with the accuracy of the results owing to a considerable oscillation of pressure arising from the action of the pump. We had remarked that when the number of strokes of the engine was suddenly reduced from twenty-seven to twenty-five per minute, a depression of the thermometer equal to some hundredth of a degree Cent. took place, a circumstance evidently owing to the entire mass of air in the coils and cotton plugs suffering dilatation, without allowing time for the escape of the consequent thermal effect. Hence it was found absolutely essential to keep the pump working at a perfectly uniform rate. For a similar reason it was also most important to prevent the oscillations in pressure due to the action of the pump, particularly as it appeared obvious that the heat evolved by the sudden increase of pressure, on the admission of a fresh supply of air from the pump, would arrive at the thermometer in a larger proportion than the cold produced by the subsequent gradual dilatation." It was for this reason that a perforated copper diaphragm, replaced afterwards by a box with perforated cups, was placed between the iron pipe and copper coil, which it is said reduced the oscillations so as to be hardly perceptible. But this could only apply to the oscillations in pressure in the copper coil. The oscillations in pressure in the iron pipe must obviously have been increased by these measures. Hence it is only reasonable to suppose that the stream of air issuing through the narrow passage from the high-pressure pipe, that is, the iron pipe, to the medium pressure or copper pipe, must have been colder owing to dilatation than when there was no such obstruction in its passage from one pipe to the other. And the temperature of this stream may very well have been so much colder, on the average, between each oscillation in temperature than the water in the bath, that it reached the porous plug before being raised to that temperature.

It would occupy too much space, and, without further experiments, be perhaps of little use to discuss the question here raised more fully. But I think enough has been said to show that Joule and Kelvin's experiments can hardly be considered to have established that there was a fall in temperature in the case of air, carbonic acid, &c., due to molecular attraction; or a rise in temperature during expansion in the case of hydrogen, due, I suppose, to molecular repulsion. With regard to this latter gas, it would pass the obstruction between the iron and copper pipes with so much greater facility than air or any other gas, that it is quite possible that it had little, if any, effect upon it. If so, since on one occasion a heating effect was obtained, even with air, before the introduction of the obstruction between the iron and copper pipes (*Phil. Trans.*, 1853, page 363), it may be that during the final experiments in 1862, with hydrogen, when a heating effect was obtained, instead of a cooling effect, as had been previously obtained with the small hand pump apparatus, the gas reached the porous plug before it had lost all the heat derived from compression in the pump cylinder. So far, then, it seems to me that Mayer's hypothesis has neither been proved nor disproved by experiment. If, hereafter, it should turn out to be true for ordinary temperatures, all uncertainty regarding the exact value of the mechanical equivalent of heat would be removed, which would be as calculated by Tyndall, 771·4 foot-pounds ("Tyndall's Heat," fourth edition, pages 70 to 72).

It will be readily seen from the foregoing that the liquefaction of gases in the exceedingly ingenious machines of Dr. Linde and Dr. Hampson is quite independent, as stated by "X." in his able article in January this year, of what is called the "Joule effect"; that is, if we mean by the "Joule effect" a fall in temperature during the expansion of a gas due to internal work being performed in overcoming molecular attraction; although, if this attraction exist, it will no doubt aid in reducing the temperature. The theory of the action of these machines seems to me to be as follows, supposing Mayer's hypothesis to be true. When the valves between the pump and pipes are closed—which must take place periodically, whether a single or double-acting pump is used—the gas in the pipes expands against external pressure, and consequently falls in temperature. The admission of the next fresh supply of gas forced in by the pump at atmospheric temperature is sufficient to warm up the gas in the pipes on the high-pressure side of the narrow orifice to its former temperature, but not sufficient to do this and in addition to warm up the gas which has escaped through the orifice in the interval between the supplies. Now, since in these machines the gas forced through the narrow orifice is made to pass back along the exterior of the pipes containing the high-pressure gas, it must tend to prevent the rise in temperature within these pipes due to the incoming gas. Hence there will be on the whole a cooling effect on each successive stroke made by the pump—slightly reduced in amount by each fresh supply of gas being warmer than that in the high-pressure pipes. Consequently as the pumping action is continued, the gas within the high-pressure pipes, and also the gas surrounding them, will continue to fall in temperature until liquefaction sets in. C. E. BASEVI.

8, Norfolk-square, W., May 19th.

CIRCULATION IN WATER-TUBE BOILERS.

SIR,—I have read with a great deal of interest the correspondence which has appeared in the engineering journals relating to the circulation in water-tube boilers. I believe I was the first to point out that the heating of the downcomers did not in any way diminish the rapidity of circulation. This statement, at first, was looked upon by some engineers as being absurd and ridiculous in the extreme. However, the experiments so ably conducted by Professor Lambert and Mr. Yarrow amply demonstrated that my theory was correct; in fact, these experiments showed that the circulation, rather than being diminished by the heating of the downcomers, was actually increased. In other words, my theory was a little more than correct.

As there still seems to be much misunderstanding in regard to what the actual cause of circulation is, and as a good deal of the reasoning which has appeared is founded on a mistaken hypothesis, I think I shall be able to simplify matters by pointing out exactly what takes place in a U-shaped tube, and why the water circulates.

If one limb of a U-shaped tube should be filled with a liquid which would weigh 15 oz., and the other with a liquid which would only weigh 10 oz., it is very evident that the heavier liquid would flow into the other limb and expel the lighter liquid, and that the flow would be just in proportion to the difference in the specific gravities of the two liquids. Suppose that the heavier liquid should consist of pure water and the lighter liquid should be composed of water mixed with some lighter substance, no matter what this substance may be, so long as it is held in suspension in the water, the circulation would take place always exactly in the degree that the one liquid was lighter specifically than the other. If this lighter material should consist of air bubbles, or steam bubbles and water, it would not make the least difference whether the bubbles were so small as to give the solution a milk-like appearance, or whether they were so large as to nearly fill the tube, the result would be the same, because it is the specific gravity of the whole mass that we have to consider. The circulation is due altogether to the difference in the specific gravities of the fluids, or fluid-like substances, in the two limbs of the tube, and to no other cause whatsoever.

It has been asserted by some writers that, so long as a continuous thread of water extends from the top to the bottom of the up-tube, the pressure in this up-tube must be identical with the pressure in the downcomer; and this mistaken hypothesis has, to my mind, been the cause of a great deal of the misunderstanding which has taken place. If a series of cork balls were strung together on a light thread, secured to the bottom of the up-tube, we should then have a continuous thread of water extending through the whole length of the tube, and the pressure would be the same as in the downcomer at all corresponding points. If these cork balls were each loaded with sufficient lead to make them exactly as heavy as the surrounding water, there would be no tension on the thread, and the result would be exactly the same. But suppose that these cork balls only weigh one-tenth part as much as a corresponding volume of water, and that they were so numerous as to occupy a third part of the volume of the tube. Suppose, now, that the thread should be cut, the balls would instantly commence to ascend the tube, and the pressure at all points in this tube would instantly fall below the pressure in the downcomer. If there were a very large communication to the downcomer, the difference in pressure would not be very great; only sufficient, of course, to cause the water to flow in and occupy the space previously occupied by the cork balls. However, if the communication between the two tubes should be restricted, it would be found that as soon as the cord was cut the pressure in the up-tube would be considerably diminished.

Some correspondents have assumed that the water circulates by an entraining action of the bubbles, believing that the bubbles move by some inherent power of their own, and in doing so take the water along with them. This is called an entraining action. When a canal boat is drawn through a canal, the water is drawn in the same direction, but at a much less velocity. In this case the canal boat moves the water and not the water the boat. But the bubbles do not move by any force inherent in themselves. Every steam or air bubble weighs something, and is drawn towards the earth exactly like any other body. These bubbles do not rise in a tube by any inherent force of their own, but because the water flows down between them, or through another tube, as the case may be, and produces a pressure on their underneath side greater than on the top side. The bubbles are therefore moved upward by the water, and not the water by the bubbles, as has been supposed by some correspondents.

The truth of all that I have said is easily demonstrated by a simple and inexpensive experiment, and if I have not made myself sufficiently clear, I propose to demonstrate the truth of what I have written by actual experiment. HIRAM S. MAXIM.

32, Victoria-street, London, S.W., May 21st.

[If Mr. Maxim tries the experiment with the cork balls, he will find that no circulation worth the name takes place. Water will descend the downcomer, and take the place of the cork in the way and for the purpose fully explained in our impression for May 15th, but not for the reason stated by Mr. Maxim in his third paragraph.—ED. E.]

THE THAMES TUNNELS.

SIR,—My attention has been called to a letter from Mr. A. Scott, which appeared in your issue of the 1st of May, in which he states that the Thames Tunnel is an obstruction with only 12ft. at low water and suggests the necessity of its removal. As one of those employed in its construction, I beg to state that the top of the tunnel is more than 36ft. below low water of spring tides. As to his complaint that the Conservators have done so little towards deepening the river, I desire to bear my testimony to the very great amount of work which they have effected in that direction with the very inadequate means at their disposal.

17, Victoria-street, May 22nd. HENRY LAW.

NEW TRAINS FOR THE FLYING SCOTSMAN SERVICE.

THERE will shortly be put into service on the East Coast route two complete trains for the through working—in the day time—between London and Edinburgh, Glasgow, Aberdeen, Dundee, and Perth, which make a distinct advance on anything hitherto designed for use in this country, or indeed in Europe, approximating as they do to the American ideal of luxury and safety. In a case like this, where a train divides into a number of portions at Edinburgh for different places, it is difficult to design a "complete" train in the full sense of the word, but it will be readily admitted that while the coaches for the different Scottish centres are complete in themselves, that yet both in outward appearance and internal arrangements the trains on the section between Edinburgh and London will show the care which has been bestowed on the designs. The coaches are all East Coast joint stock; that is to say, they are the property of the three companies—the Great Northern, the North-Eastern, and the North British—and are built from designs agreed upon by the officers of the three companies, and used for the joint service only. Each train consists of eight coaches, carried on a pair of six-wheeled bogies—*i.e.*, twelve wheels under each coach—and having an extreme height of 13ft. 5in. from the rails, clerestory roofs, patent torpedo ventilators, double gas lights, Gold's patent steam heating apparatus, and a complete arrangement of electric bells from each compartment by which the attendant can be called if required. Externally the coaches are finished in selected teak, varnished, picked out with gold lines and with large gold lettering, and ornamented with the East Coast joint arms in the centre, and at either end the old coats of arms of England and Scotland respectively, from special designs, which give the exterior a very handsome appearance. The public will fully appreciate the long scarlet destination boards, with bold gold letters conveying all information necessary to the easy finding of the right through coach. In the long corridors are ingenious skeleton route maps showing the principal stations, branch lines, and junctions, the mileage, &c., which will be of interest to the traveller who is unfamiliar with the route, and who wants to know "Where we are now," and which with the large maps placed at intervals on the doors in the corridors, and the fold-up seats also fitted therein, make the long promenade from end to end of the train a pleasant place in which to pass away the time. The whole of the floors in the train are laid with thick Kork matting, a material both noiseless and warm. In the meantime the first and last vehicle of each train will be a standard East Coast six-wheeled van, but as soon as the present pressure in the shops allows, a long twelve-wheeled "van and third composite" coach will be built for the front and tail of the train. Two entire novelties, so far as this country is concerned, which will add much to the safety and comfort of the passengers, are introduced in these trains—namely, the patent Gould combined vestibule, automatic coupler, buffer, and continuous platform, and the quick-action Westinghouse brake. The system of side buffers and screw-up couplings, which is universal in this country, has never been used in America, and the gradual abolition of so unsatisfactory a system means a great increase in the haulage capacity of the locomotives, as it is evident that on a curve a considerable amount of the power of the engine is employed in compressing the inner buffers. The Gould centre coupler and buffer is a very powerful steel apparatus like a gigantic mark of interrogation (?) on its side, and is the kind most favoured in America. It is automatic in its action; that is to say, when the coaches are pressed together the two couplers engage at once, and all the usual dangers which arise where shunters have to work between moving carriages are dispensed with, as it is only necessary to couple up the brake and steam heating pipes and the electric communication wires after the coaches are at rest, and are practically one. The coupler is held in position by springs of enormous strength, which, while they allow the coupler to act like a great hinge on curves, in the case of a collision act with great resistance in absorbing the dangerous forces which result in telescoping. The coaches are fitted also with the standard British side buffers, so that when necessary vehicles not fitted with Gould couplers may be added to the train; but these side buffers are kept quite out of play, so as not to interfere with the gain in haulage which results from the flexibility of centre buffers—at the same time these side buffers will be a great help if the coaches begin to crush together in a collision, as they will act as additional springs, throwing the stresses on to the outer frames. But the greatest gain of all in the way of safety is in the adoption of the Gould continuous platform and solid vestibule, which make the train practically one vehicle from end to end. The end of the coach sweeps out in a semicircle like the stern of a ship, forming an enclosed and covered platform which almost meets the corresponding one on the next coach, the intervening space being bridged over by the Gould vestibule, which is an ample steel gangway, 3ft. wide and 6½ft. high, which automatically interlocks, without bolts or clamps, when the coaches meet. Telescoping, which is the cause of most of the deaths in collisions, is practically unknown where centre couplers are combined with solid vestibules, which throw part of the terrible crushing force on to the sides and roof of the carriages, instead of on to the frame alone.

Every wheel of the train is fitted with quick-action Westinghouse brakes, an improved form of brake which is practically instantaneous in its action, and which stops a train at full speed in less than half the distance required by the brakes now in use in this country; this brake has been generally adopted in America, Australia, Belgium, &c., for some years both for coaches and goods trucks, but hitherto this country has been backward in such matters. The Gould couplers, vestibules, &c., and the quick-action Westinghouse will in future be fitted on all East Coast joint stock, on which the automatic vacuum brake is also fitted. On each train there is one third-class open carriage, entered by doors at the ends only, thereby abolishing the draughts and general discomfort inseparable from side doors, and having a passage right down the centre; it is divided into three sections, holding twenty-three, sixteen, and fifteen passengers, or fifty-four in all, and at one end are the lavatories, a large luggage compartment, and the attendant's room. The introduction of an attendant who will have the sole duty of waiting on the passengers, who can call him by the bell in each compartment, will be much appreciated, especially when it is known that he has arrangements for supplying tea, coffee, and light refreshments *en route*. The passenger compartments are trimmed with combination velvet in crimson and black, with silk laces, &c., to match. This coach is 66ft. 10in. long and 9ft. wide, and, with its light and airy feeling of freedom, should be very popular. There is also one third-class corridor carriage, 66ft. 10in. long and 8ft. 6in. wide, having nine separate compartments, seating fifty-four passengers, and the usual lavatories. In the centre of the train are four composite corridor carriages, each 65ft. 10in. long and 8ft. 6in. wide; for the Glasgow, Perth, and Aberdeen service each is complete in itself, containing three first-class and four third-class compartments, ample luggage room, and separate lavatories for each class, the first-class compartments being trimmed in fine blue cloth, crimson laces, holder lace, &c., and provided with mirrors; the third-class in crimson and black combination velvet, and lace to match. The composite carriage brakes for the ends of the trains will be 62ft. 7in. long and 8ft. wide—with side inspection projections for the guard—and uniform with the rest of the train, and will accommodate four third-class compartments and a lavatory, besides a luggage van 32ft. long. Each train will be over 530ft. long, will weigh about 270 tons, and carry exactly 300 passengers, and from these statistics and general notes it will be seen that the whole arrangements have been made with the intention of producing trains which will not only be very luxurious, but present a handsome appearance, and afford a highly-paying accommodation space, a happy combination both for the public and the companies. The trains have been built at the Great Northern works at Doncaster, and the chief work of the designing, as well as the complete construction, has been carried out by Mr. E. F. Howlden, the carriage superintendent, in a most satisfactory manner.—*The Scotsman, May 25th*, 1896.

THE INSTITUTION OF CIVIL ENGINEERS.

MAGNETIC PROPERTIES OF IRON AND STEEL.

AT the ordinary meeting on Tuesday, May 19th, Sir Benjamin Baker, K.C.M.G., the President, in the chair, two communications dealing with the magnetic properties of iron and steel were considered.

The first paper was entitled, "The Magnetic Testing of Iron and Steel," by Professor J. A. Ewing, F.R.S., M. Inst. C.E. The author referred to the practical importance which now attached to the magnetic testing of iron and steel in relation to the manufacture of dynamos and transformers. From being a mere laboratory experiment, interesting only to students of physics, it had passed into the rank of an engineering operation. Ironmakers now supplied material greatly superior, from the magnetic point of view, to that which could be obtained even two or three years ago. In dynamo construction the introduction of permeable steel castings for the field magnets had given greater latitude as to form without loss of efficiency, the best steel castings being indeed somewhat better magnetically than most forged iron. In stampings of sheet metal for transformers the main consideration was absence of hysteresis, and so great had been the advance in this respect that iron was now readily obtainable with only half the amount of hysteresis which was considered possible a few years ago. This had brought about a notable increase in the efficiency of alternate-current distribution, by reducing the large element of loss which occurred through the hysteresis of transformed cores during the hours of light load as well as of heavy load. The author recalled the conventions according to which the magnetic quality of iron was expressed. The most usual test was one to determine the relation of the magnetic induction to the magnetising force, the ratio of B to H being the permeability. To enable H to be determined with accuracy, the specimen was arranged as a closed ring, or as an ellipsoid, or as a bar or bars rendered practically endless by the use of a yoke. Ballistic methods of testing were described, and it was shown how in the use of a yoke a proper correction might be experimentally found, to deduce the true magnetising force, by allowing for the magnetic resistance of the yoke itself. For this purpose the author used a pair of bars, joined by two short yokes at their ends, the yokes being shifted so as to include either the whole length or half the length of the bars in the magnetic circuit. Reference was made to various forms of apparatus designed to measure the magnetic induction by observing the force required to separate surfaces in the magnetised piece, and a form used by the author was described, in which a yoke piece was simultaneously drawn away from polar extensions at both ends of the bar. A novel apparatus was shown in detail for measuring permeability by comparing the magnetising force required to produce a given induction with the force required to produce equal induction in a standard bar. This apparatus, which the author terms a magnetic bridge, from its analogy to the Wheatstone bridge for the measurement of resistance, reduced the operation of testing to a comparison between the specimen and a bar the magnetic quality of which had been determined once for all by the instrument maker. The two bars were connected by end yokes, and by varying the number of turns in the magnetising coil on one of them, the yokes were brought to the same magnetic potential. The relative number of turns on the two thus gave the relative magnetising forces required to produce the same induction in both. A simple form of magnetic detector showed when the two yokes were brought to the same potential. The manipulation consisted in varying the number of turns acting on one bar by means of dial switches, while the magnetising current was from time to time reversed. This permeability tester was intended for workshop use, and might take its place alongside of the author's hysteresis tester, which was also described. The methods of directly measuring hysteresis were briefly referred to.

A number of representative examples were given of permeability tests of forged wrought iron, forged steel and cast steel for dynamo magnets; also of hysteresis tests of transformer plate rolled from

Swedish wrought iron and from ingot metal. The results were shown by means of numerical tables and also in curves.

The second paper, on "Magnetic Data of Iron and Steel," was by Mr. H. F. Parshall, Assoc. M. Inst. C.E. Magnetic tests of iron and steel might be conducted to determine such properties as permeability, maximum magnetisation, residual magnetism, and permanent magnetism, and the relation they bore to tempering, annealing, internal stresses, composition, and processes of manufacture. The loss of energy through hysteresis might be determined either magnetically by determining the area of the loop formed by plotting the flux densities as ordinates, and magnetic force as abscissæ, or mechanically by suitable power-measuring apparatus. A study of the magnetic results and of the chemical analysis showed a more or less intimate relationship according to the degree with which the modifying physical conditions might be controlled. In general, a greater degree of purity was an indication of high permeability, but as the different qualities of iron and steel merged into each other by insensible degrees, owing to variations in the processes of manufacture, chemical analysis might be taken only as an approximate indication of the magnetic properties. Carbon was the most important element entering into the composition of commercial iron, and within the limits that chemical analysis might serve as an indication of the physical structure, the permeability was inversely as the amount of carbon present. The limitation as to the state of physical structure was greatly affected by the state of the carbon, that was, whether free or combined; in cast iron as well as in steel, the effect of graphite was second to that of the carbide, commonly known as fixed or combined carbon.

Beyond a certain degree of purity, as in wrought iron and carbon steels, the treatment as to annealing and tempering became of first importance. The magnetic properties of some of the alloys of iron, nickel, or manganese were such as to show that the physical structure was the ultimate determining factor. The hysteresis loss was in general inversely as the degree of purity, but in comparatively pure irons it was determined principally by its treatment as to annealing, heating, and mechanical straining.

LAUNCHES AND TRIAL TRIPS.

THE transport steamer Sir Evelyn Wood, recently built and engined by Messrs. Fleming and Ferguson, Paisley, went down the Firth on her trial a few days ago, attaining, on a six hours' run, a speed of 10 knots, being in excess of guaranteed speed, and everything working smoothly and to the complete satisfaction of the Government officials on Board.

The twin-screw steamer Barcellos, built by Messrs. A. Rodgers and Co., Port Glasgow, and engined by Messrs. Hall, Brown, Buttery, and Co., Govan, was successfully tried on the measured mile in the Gareloch on the 21st inst., when a speed of 10½ knots was easily obtained. This vessel is a sister ship to the Sapucaia, both being owned by the Amazon Steam Navigation Company, London, and built under the superintendence of James Pollock, their engineer. The vessels are fitted with all the latest improvements for the special trade in which they will be engaged. The dimensions are 170ft. by 28ft. by 10ft. 6in., and in trial the vessels were fully loaded with coal. The engines are on the triple-expansion principle, working at a pressure of 165 lb. Both vessels were ordered early in February, so that they have been handed over within three and a-half months from the date of order.

On Tuesday, the 26th inst., Messrs. Wigham, Richardson, and Co. launched from their Neptune Shipyard a steamer named the Innisfallen, which they are building to the order of the City of Cork Steam Packet Company, of Cork. The Innisfallen is the third steamer built for this company by Wigham, Richardson, and Co. The vessel is built of steel, with very fine lines, and is intended for the passenger service between Milford and Cork, in conjunction with a special service of fast trains from London. She is 283ft. in length by 35½ft. beam, and will have luxurious accommodation for a large number of first and second-class passengers. She will also be fitted up for carrying a large number of cattle, besides being able to be converted into a troopship should occasion arise. The propelling machinery is also being constructed by Messrs. Wigham, Richardson and Co., the engines being of the four-crank triple expansion type, working at 160 lb. pressure, and balanced on the well-known Yarrow, Schlick, and Tweedy system, which, owing to the entire absence of vibrations, is peculiarly suitable for passenger steamers. Amongst the company who viewed the launch were Major Lyons, chairman of the City of Cork Steam Packet Company, Mr. Christie, and Mr. Tweedy, of the builders' firm. The christening ceremony was performed by Miss Hicks, daughter of the Rev. Canon Hicks, of Tynemouth.

On Saturday, the 23rd inst., the new steamer Loongmoon, which has been built and engined by Messrs. Wigham, Richardson, and Co., of Newcastle-on-Tyne, for the Chinesische Kustenfahrt Gesellschaft, of Hamburg, completed a very satisfactory trial trip. The vessel is built of steel, 310ft. in length by 38½ft. beam, rigged as a two-masted schooner, and has been built to take the highest classes in the registries of the Bureau Veritas and Germanischer Lloyd. She has been specially constructed for the Eastern Coasting Service of this company, and is well supplied with all the most modern appliances for working both the cargo and the vessel. She has also handsome, well-ventilated and convenient accommodation for a large number of native and European passengers. The engines and boilers have also been constructed by Messrs. Wigham, Richardson, and Co., the former being of the quadruple type, self-balanced on the Yarrow, Schlick, and Tweedy system. During the trial trip they worked most satisfactorily, driving the vessel at a speed of 12⅝ knots. Amongst the company on board the vessel were Mr. John Tweedy, of the builders' firm; Mr. Hubbe, director of the Chinesische Gesellschaft, and Mr. Schlick, the technical adviser of the company; and Captain Kohler, who has taken command of the vessel, Mr. Muir, and representatives of the Board of Trade, the Bureau Veritas, and other gentlemen. The Loongmoon is the fifth vessel built by Messrs. Wigham, Richardson, and Co. for the coasting passenger trade of this company, and is a very handsome addition to their fleet.

The steel screw steamer Carlow, built and engined by Messrs. Blackwood and Gordon, Castle Building-yard, Port Glasgow, for the City of Dublin Steam Packet Company, Dublin, went down the Firth on the 19th inst. on her official trial, in favourable weather. Her dimensions are:—Length, 260ft.; breadth, 34ft.; depth to main deck, 16ft. 9in.; with full poop, long bridge and forecastle, having short breaks filled in with planking, which gives a continuous upper deck; gross tonnage, 1284 tons. The vessel has been built very much in excess of Lloyd's scantlings in view of the particular trade for which she is intended—*i.e.*, Dublin to Liverpool—and has also been fitted with deep rolling chocks to minimise the rolling motion in heavy weather. In the holds water ballast tanks are placed, which can be separately filled and emptied, being connected by pipes to ballast engines in the engine-room. The machinery, which has also been constructed by Messrs. Blackwood and Gordon, is of the triple-expansion type, of fully 3000-horse power, and is supplied with steam from two large double-ended boilers working up to 170 lb. pressure. The vessel and her machinery has been constructed under the superintendence of Mr. E. G. Ferber, of Liverpool, the engineering superintendent of the City of Dublin Steam Packet Company. The speed attained was fully 15¼ knots on a four hours' run. The distance between Dublin and Liverpool is 120 knots, and Mr. W. Watson said they were constantly doing the passage under eight hours, which was a speed of 15 knots. Proposing "The City of Dublin Steam Packet Company," owners of the Carlow, the chairman said this company was the oldest steamship company in this country, having been founded in 1823. This company had for nearly sixty years had the honour and privilege of carrying her Majesty's mails between Ireland and England, and they had recently entered into a new contract with her Majesty's Government, to fulfil which they were building four new twin-screw steamers, to attain a speed of 23 knots, and when they came to occupy the station they would shorten the passages between Kingstown and Holyhead by half an hour.

AUSTRALIAN NOTES.

THE information concerning the particulars of the mineral resources of New South Wales, as published by the Mines Department, is not yet officially before the public for the year 1895, the delay being caused in consequence of the reports being held over until Parliament meets However, the principal statistics have been submitted for press review. The total value of all the mineral products for the year 1895 was £4,552,018, being a decrease of £504,118 on the value won in 1894. The following are the values of the principal items:—Gold, £1,315,929; silver, £81,858; silver, lead, and ores, £1,560,813; coal, £1,095,327; shale, £75,218; coke, £24,683; tin, £138,623; copper, £140,885; iron, £15,620; antimony, £7251; chrome, £13,048; limestone (flux), £68,160; the noble opal, £6000. The increases for 1895 were:—Gold, £159,211; shale, £43,437; copper, £67,404; chrome, £712. The principal decreases were:—Silver, £12,292; silver, lead, and ores, £634,526. The decrease in the value of the output of silver is evidently due to a greater quantity of lower grade ores being produced during the past year, the tonnage being nearly 40,000 tons in excess of 1894.

Coal shows a decrease of £60,426, notwithstanding there being an increase in quantity of 66,500 tons. This is considered to be due to the low price prevailing.

The prospects for gold mining are very encouraging, as, notwithstanding the adverse circumstances met with on account of the drought, the returns show a substantial increase. The impetus given to gold mining in this Colony is due in a great measure to the scheme of sending the unemployed throughout the Colony to "fossick."

The Broken Hill Proprietary Company are still saving gold in connection with their silver mining operations, the quantity last year being 4650 oz., valued at £18,600. The report gives a table showing the yields and value of the quartz mines in the various districts as under:—

District.	Tons.	Yield.	Average.		
		oz.	oz.	dwt.	gr.
Bathurst	17,541	83,958	4	15	17
Tambaroora	3,784	2,749	0	14	12
Lachlan	19,223	27,202	1	8	7
Southern	6,007	3,278	0	10	21
Tumut	5,488	5,210	0	18	23
Peel	43,137	28,878	0	13	9
Hunter	449	336	0	14	23
Clarence	3,068	2,652	0	17	7
Mudgee	15,088	9,169	0	12	7
Cobar	12,507	6,601	0	10	13
New England	2,139	3,769	1	15	5

A strike is again contemplated throughout the Newcastle coalfields against a further reduction of pay. It is to be deplored that some arrangement cannot be agreed upon amongst the colliery proprietors for a fixed rate for coal, so as to place the miners on a better footing. According to the official returns of the Government, the ruling price of coal for the past year was the lowest on record since the commencement of coal mining in the Colony.

A deal of consternation has lately been caused among coal shippers in consequence of heated coal cargoes; hitherto it was considered perfectly safe to ship the Newcastle coal in any weather, but within the last two months three coal-laden ships have had to get their cargo broached in consequence of over-heating, one vessel, the Knight of St. Michael, having to return to port after being several days out. The absence of gases in the pits was thought to be a safeguard against any over-heating. From investigations that have since been made it has been considered that the causes of the over-heating have been through the friction of shooting the coal from a great height into the holds of the ships, and also through loading in wet weather.

In addition to the smelting works now being erected in the Illawarra district, under the management of Mr. J. Howell, it is understood a company is about to erect a smelting works for the treatment of sulphide ores in the Newcastle district, at a cost of between £50,000 and £60,000.

Since the inauguration of the Public Service Commission for New South Wales—a body to fulfil duties similar to those of the Civil Service Commission in London, but with greater powers—several important changes have already taken place, one of the principal ones being the retirement from the chairmanship of the Metropolitan Water Supply and Sewage Board of Mr. C. W. Darley, who becomes Engineer-in-Chief in the Works Department.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, May 20th.

STEEL makers are making additional slight concessions this week to stimulate the placing of orders for finished products, particularly in plates and shapes, but without success in any degree. While there is admittedly a great deal of bridge building to be done, and that too before the approach of cold weather, there is an indifference on the part of railway managers and others to inaugurate work. There is also a large amount of elevated railroad work, terminal work, track repairing and extension, and so on, that railway people say must be attended to, but the attractions of extremely low quotations and arguments that prices may advance later on do not have any effect.

Our Pennsylvania mills are monopolising the cream of the trade, and especially in Western Pennsylvania. Some mills have two months' work secured. Pig iron production does not decline, but prices weaken. Even at shaded quotations it is no easy matter to move lots of 5000 tons for mills. Charcoal iron is doing better, but Bessemer pig is neglected almost completely. The steel billet people loaded up a big gun, but the middleman kept them from firing it off. There will be no change until July, when all authorities agree business will improve. Steel rails are picking up in the West, where a great many roads are doing repairs. Some are building small extensions. All need more rolling stock, but have to get along as best they can. The bar mills are slack, but to-day's report from Pennsylvania sheet mills assures us there is a steady demand for sheets. Wrought iron pipe mills have many recent inquiries. Merchant steel is also in better demand. Summing up the entire situation, it must be admitted business in iron and steel is below its normal level. The one needed factor, as before said, is railroad building. Of late nearly all our railroad building is on paper. Should capital turn in this direction, nothing could prevent or long check a general rise in values in furnace and mill products. There is activity in the Lake ore regions, and in the coal and coke regions, but the requirements do not permit very remunerative quotations.

The people are thinking more of the Protection sweep they are to make this autumn.

THE costliness of wooden petroleum barrels, which have advanced in the last few years from 1·50 to 4·50 florins in Austria-Hungary, besides requiring repairs after long use, has induced Consul Schwimmer, in Budapest, to erect, under assistance of other capitalists, large works for the manufacture of iron barrels, welded by electricity after the latest process. These barrels will cheapen the price of petroleum, and the usual loss attending the use of wooden barrels is avoided.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

THE attendance at to-day's Birmingham market was of a holiday character, and the business done was of a perfunctory nature, and insufficient to base quotations upon, which it is understood remain unaltered since last week. Most of the works, what with holidays, repairs, stock taking, &c., will not restart till the beginning of next week.

Increased local attention is being paid to phosphorus. When the basic steel process was adopted it was found that the phosphorus in the basic pig could be used as a heat producer in place of the silicon formerly employed with the old Bessemer process, but which, if used in the basic process, rapidly, by its acid action, destroyed the basic lining of the connection. For some time a large quantity of puddled tap cinder was bought up in South Staffordshire by continental ironmasters and shipped from this country for use in their own blast furnaces, the result of which is that phosphoric puddled cinder, which ten years ago could frequently be had almost for the asking, has risen in South Staffordshire to over 5s. per ton, and appears likely to touch as much as 10s. per ton. The effect has been a considerable increase in the cost of the charges for the local makes of basic pig iron. Under these circumstances other methods of obtaining phosphorus have been adopted on the Continent, especially in the Luxemburg and Lorraine districts, such as adding some portion of the basic slag from previous blow to the blast furnace, and ores richer in phosphorus are imported from other countries, to give the phosphorus required in the pig. As much of this ore has to be brought long distances, it is obviously important to keep down the total quantity carried to the lowest possible limit. We have, therefore, the remarkable result that the higher the content of phosphorus which some of these ores contain the better the price the continental ironmaster can afford to pay, so that in some instances ore is actually being purchased and valued at the present time in proportion to its phosphorus contents. Had anyone been bold enough to predict such a state of things some years previously he would have been considered out of his mind; so greatly has the basic process altered our opinions on the subject of phosphorus, which has ceased to be a terror to the steel maker. Some of the ores used on the Continent as an alternative to the employment of Staffordshire tap cinder are imported from long distances—for instance, from Gellivara, in the north of Sweden, where some of the ore is very rich in phosphorus, pig iron having positively been made from it containing as much as 10 to 13 per cent. of phosphorus, with as little as 0·1 per cent. of silicon, which latter, to the Bessemer basic steel maker, is almost the same bugbear that phosphorus was to the old Bessemer acid steel maker.

G. Kynoch and Co., the noted ammunition makers, recommend a dividend of 10 per cent. on the preference and 13 per cent. on the ordinary shares. They have made a profit on the year of more than £29,000, and to this they add a favourable balance brought over from last year of £12,500. They carry £18,400 to next account. The Lion Works at Wilton, and the Rolling Mills at Lodge-road, have been fully employed during the past year; and the directors have wisely taken advantage of this state of prosperity to repair or replace a large proportion of the engines and machinery. The Black Powder Mills at Worsborough Dale have been continuously employed day and night, at remunerative prices. The Arklow Nitro-Explosives Works have been completed, and the output raised to nearly double the contemplated amount. The Government is being supplied to the full extent of its requirements, and orders from the private trade are coming in satisfactorily.

With regard to the boom in cycle engineering, holiday influences have caused a lull in speculation; one or two recent issues of new companies were not, in fact, quite covered, but there is no reason to suppose that company promoters have yet done with the cycle trade, or that we have reached the end of the list of new undertakings due to their enterprise. Several additional ventures are known to be on the stocks, and are only waiting an opportune moment to be launched. It is estimated that during the past two months some twenty-four new companies have been floated—chiefly in the Midlands—with an aggregate capital of nearly £7,500,000, and of this large amount £4,000,000 is absorbed by a single company, the Dunlop Pneumatic. The cycle engineering industry and its tributaries must indeed be in a wonderfully prosperous state to justify this extensive diversion of capital from private pockets, more especially when it is remembered that a large proportion of these issues have come upon the market at high premiums, ranging from ten or twenty to several hundreds per cent.

Light railway engineers have received with much satisfaction the opinions just expressed by Lord Winchilsea at a public meeting held at the Council House, Birmingham, under the auspices of the Warwickshire Chamber of Agriculture and Midland Farmers' Club, for the purpose of considering how home producers may hold their own against foreign competition by organisation and combination. The Earl thinks we require a better system of collecting agricultural produce in rural districts, so that advantage may be taken of the cheap through rates offered by the railway companies; combination in different branches or departments of the industry, with a view to economy and equality of production; and central depôts, from which the produce received in bulk could be economically and advantageously distributed to consumers. Birmingham, owing to its central position, is certainly well fitted to co-operate in such a work, and though its traditions and associations are connected with the hammer and the anvil rather than the plough, there is no reason why it should not give a cordial response to Lord Winchilsea's invitation. The freer use of road locomotives, the introduction of light railways, the use of agricultural forms of mechanical carriage—these are all methods in which the Earl's idea might usefully be carried out, and it need hardly be pointed out that they are methods also which would considerably assist Midland manufacturers. Dairy engineers were also pleased to find on the same occasion in Lord Winchilsea a strong advocate of the factory system of dairy farming which has been adopted with such success in the Colonies and on the Continent, and that is only possible, of course, by organised co-operation on a large scale.

The North Staffordshire Chamber of Commerce in its annual report regrets that no substantial progress has been made regarding railway rates on earthenware, and trusts it will not be necessary to carry the matter to the Railway Commissioners.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—During the past week there has been the customary stoppage of operations throughout the iron, engineering, and coal trades of this district. Most of the principal engineering works have been closed over the whole of the week; and collieries in the immediate neighbourhood of Manchester, which closed about noon on Tuesday, will scarcely get into full operation again until about Wednesday in next week; whilst in other Lancashire districts, even where Whitsuntide is not so fully observed, there have also been more or less general partial stoppages of the pits. For the time being there is consequently very little to report with regard to actual trade operations; but with engineering establishments all through, and most of the iron-using industries well supplied with orders, a healthy position is maintained so far as prospective requirements are concerned, and although for the time being prices for both raw and manufactured iron continue weak for immediate delivery, the outlook generally is regarded hopefully.

Although Tuesday was the only 'Change meeting at Manchester for the iron market, there was but a very thin attendance, and scarcely anything doing to really test prices. For local and district brands of pig iron makers hold to late rates, averaging 46s. 6d., less 2½, for No. 3 foundry Lancashire; 40s. 6d. for forge to 43s. for foundry Lincolnshire; and 45s. 6d. to 46s. for foundry Derbyshire, net cash, delivered Manchester, with, however, low sellers of Lincolnshire in the open market. Outside brands offering here show some irregularity in price, the tendency being, if anything, to harden, but business is scarcely possible except at very low cut figures. Makers scarcely quote under 45s. 10d. to 46s. 4d. for good-named foundry Middlesbrough, delivered Manchester, but through second-hands ordinary brands are obtainable at quite 6d. less, whilst for delivery Manchester Docks about 44s. remains the average figure for good brands. Eglinton ranges from 46s. to 46s. 6d., and Glengarnock is quoted 47s. net prompt cash, delivered Lancashire ports, and 48s. 6d. for Eglinton, to 49s. for Glengarnock, are the average figures for delivery Dock Quays, Manchester.

With regard to finished iron a fairly steady tone is maintained generally. Local makers do not, as a rule, quote under £5 10s. for bars, and North Staffordshire qualities range from £5 10s. to £5 15s., delivered here; but one of the largest Lancashire makers are rather anxious sellers, and this tends to weaken the market. Sheets and hoops are unchanged, averaging £6 17s. 6d. to £7 2s. 6d., and £7 5s. for sheets, according to quality, and £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths of hoops, delivered Manchester district, with 2s. 6d. less for shipment.

In the steel trade there is an active demand for forgings, and also for some descriptions of manufactured goods, and prices generally are very firm at late rates. Makers still hold to 58s., less 2½, for good foundry hematites, although merchants would take 6d. less, with steel billets averaging £4 7s. 6d. net cash. Steel bars are still quoted very low, but are steady at £6 to £6 2s. 6d.; boiler plates also show no appreciable improvement, £6 5s. to £6 7s. 6d. remaining the average figures for delivery in this district.

An improved spoke bending machine, for dealing with the wrought iron spokes of railway carriage and wagon wheels, has just been constructed to special designs by Messrs. Cunliffe and Croom, of the Broughton Ironworks, Manchester. In this machine the power of the gearing and the strength of the machine throughout have been largely increased, as compared with previous machines of the same class, in order that it may be capable of bending and blocking effectually the largest sizes of thickened-back spokes, which are now in so general demand. The machine is driven by an engine attached to it, and a special arrangement is introduced whereby the stopping and starting is controlled by friction cones, which can be instantly put in or out of operation, so that there is no necessity to stop and start the steam engine, whilst this device also removes any risk of breakage. The machine will bend the spokes at the rate of six per minute, and block them to the exact shape required, an automatic attachment being provided for raising the spokes out of the dies after they have been operated upon. The firm has also in hand, besides ordinary work, a large number of machine tools, specially designed for the motors now being introduced for horseless carriages, &c., and also for cycle manufacturing operations.

Messrs. Statham and Sons, Windsor Bridge, Salford, have introduced a new hearth boxing—Moore's patent—constructed of steel or iron, to take the place of the usual brick or trimmer arches, which are frequently very difficult to fix firmly in position. This boxing, which, I understand, is being adopted by many builders and architects, consists of an arched steel plate ⅛in. to $\frac{3}{16}$in. thick, at one end of which is a 1½in. flange and at the other a back-plate containing two screw-holes. In fixing the boxing, the small flange is let into the chimney breast, and the back-plate is bolted to the trimmer joist, after which the space between the floor-line and the plate is filled in with concrete, or any other incombustible material.

In the coal trade there has been some pressure to get in extra supplies, just prior to the holiday stoppages of the pits, but this has fallen chiefly upon the lower class fuels suitable for engine purposes. The better qualities of round coal continue only in slow request. Although there is nominally no quotable change in list rates, prices are very irregular, and even where concessions are made, it is difficult to effect sales. Apart from one or two special qualities 10s. is a full average figure for best Wigan Arley; 8s. to 8s. 6d. for Pemberton 4ft. and seconds Arley; and about 6s. 9d. to 7s. 3d. for common households. Common round coals, for steam and forge purposes, also continue difficult to move, and extremely low in price, 5s. 6d. to 6s. at the pit mouth being about the average figures. The restricted production of slack, owing to the very limited demand upon round coals, is causing rather a scarcity of engine fuel on the market, and the pressure for extra supplies during the past week has given a hardening tendency to prices, but no general advance is being got, and at the pit mouth common ordinary slacks remain at 3s. to 3s. 6d., and best qualities 4s. 6d. to 5s. per ton.

For shipment, business shows no improvement, and prices are quite as low as ever, common steam coal being obtainable, delivered Lancashire ports, at 6s. 9d. to 7s., and delivered free of toll at the Partington tips, Manchester Ship Canal, at 7s. per ton.

Barrow.—The demand for hematite qualities of pig iron is steady, although during the week the amount of business doing has been necessarily limited on account of two or three days having been taken for the holidays. The inquiry, however, is well maintained on home as well as on foreign and continental account, and makers being already well sold forward have a good outlook for the future. There are thirty-nine furnaces in blast as compared with twenty-eight in the corresponding week of last year, and the fact that all the iron produced is going into consumption is shown in the steadiness of stocks, which remain as last week at 308,647 tons, being an increase of 19,472 tons since the beginning of the year. Prices are steady at 49s. for mixed Bessemer Nos., net f.o.b. Warrant iron is at 47s. 4½d. net cash sellers, 47s. 4d. buyers.

Iron ore is in steady request, and average qualities are quoted at 10s., and best descriptions at 12s. 6d. to 14s. 6d. per ton net at mines. These quotations have been steadily held now for some months. Spanish ore is in brisk demand, and is largely imported to local smelters. Prices are quoted at 12s. to 12s. 6d. per ton net at West Coast ports.

The steel trade is brisk, and makers have plenty of orders in hand. Rails are especially busy, and all classes of shipbuilding material are in brisk request. All other branches of the steel trade are busy, with the solitary exception of tin bars, and the trade in these is checked by the action of the American tariff.

Shipbuilders and marine engineers do not report any new orders, but the inquiry for new tonnage in the open market is more pronounced than it has been, and it is evident some large orders will soon be placed with British builders, of which Barrow builders hope to get a fair share. Much interest has been taken this week in the dock steam trials of H.M.S. Powerful, first-class cruiser, which have passed off very satisfactorily.

The coal and coke trades are busy and the demand is maintained all round, and especially so by manufacturers. Prices, however, do not show much improvement or even change, although it is expected there will be an advance in the price of coke now that more furnaces are going into blast.

Shipments of pig iron from West Coast ports during last week reached 2510 tons, and of steel 12,551 tons, as compared with 6080 tons of pig iron and 13,013 tons of steel in the corresponding week of last year, a decrease of 3570 tons of pig iron and 462 tons of steel. The aggregate shipments this year to date have reached 123,205 tons of pig iron and 189,751 tons of steel, as compared with 105,622 tons of pig iron and 144,569 tons of steel in the corresponding period of last year, an increase of 17,583 tons of pig iron and 45,182 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THIS has largely been a holiday week. The exceptionally fine weather on Whitsun-Monday caused an enormous exodus from all the working districts. In the larger establishments where work is pressing the holidays have been limited to the half of the week, but no great volume of work will be turned out. Whitsuntide and Christmas are the two seasons when advantage is offered for repairs to machinery and alterations. These are being vigorously proceeded with while this is written, and the boiler makers and repairers are excessively busy in work of this kind.

Very little change has taken place in the house and other departments of the coal industry of late, nor is there the slightest likelihood of much alteration at present. Four to five days a week have formed the maximum of weekly employment, and even with this restricted labour the output still continues considerably in advance of the demand. Reports from agents in the metropolis show that the competition is largely in favour of seaborne fuel, on account of the rates of carriage being so much less. The decision of London merchants to declare lowest summer prices from June 1st may have the effect of causing consumers to lay in stocks. A very poor tonnage is being sent to London, both of Silkstone and Barnsley house coal, and a similar remark applies to the Eastern Counties. No improvement has taken place in the values of house coal, and considering the number of new collieries being opened out, it is difficult to see when an advance will take place. One interesting item has been the placing of Midland Railway Company's contracts for the supply of hard steam coal for the next twelve months. Tenders have been accepted at 7s. per ton from Barnsley, and 6s. 3d. from the Parkgate bed. These quotations are on the basis of existing contracts, and quite equal to the prices quoted in the open market.

Quotations in the Barnsley district range as follows:—Silkstone coal, 8s. to 8s. 3d. per ton for the best; 7s. to 7s. 6d. for secondary qualities; Barnsley house coal makes 7s. to 7s. 6d. per ton, while thin seam coal can be bought at 6s. to 6s. 3d. per ton at the pits. Gas coal is again in poor demand, and there is very little business doing outside contracts. Prices range from 7s to 7s. 3d., whilst 6s. to 6s. 3d. is all that can be obtained for Parkgate and similar thin seam qualities. A large tonnage of the best South Yorkshire "hards" is going to Hull to be shipped to Sweden, Norway, North Russia, and Germany. Yorkshire trade with Grimsby is on the mend, notwithstanding the keen competition of Derbyshire coal. Only a moderate business is being transacted by South Yorkshire pits with Goole, the bulk of the trade being done by the West Yorkshire collieries. Railway companies have drawn a large quantity of coal under contracts owing to increased traffic caused by the Whitsuntide holidays. An advance in the demand for coke has materially assisted the consumption of small coal and slack, and prices have slightly increased. Best screened slack is making from 3s. 3d. to 3s. 6d.; ordinary pit slack, 2s. 6d. to 2s. 9d. per ton; smudge is easily sold at 1s. 6d. to 2s. per ton. An average tonnage has been sent to the manufacturing districts. Coke is in good demand. A large tonnage is being sent to North Lincolnshire, Derbyshire, and other places. Prices range from 8s. 6d. to 11s., and in a few instances 12s. is obtained for best washed coke.

The heavy industries continue to be fully employed. All the large works are full of employment. Some good orders for railway material have recently come in from India and the Argentine Republic. State carriages for the Royal Railway Department, Siam, are being completed. The marine departments are very much busier on account of an expansion of the shipbuilding industry. One of the most encouraging features of the trade is the steadiness of the values of iron and the finished material. Pig iron has been steady for three months now. Bessemer billets realise £5 12s. 6d. to £6; Lincolnshire forge iron, 39s. to 40s.; ditto foundry, 41s. to 42s.; bar iron, £5 10s.; hematites as quoted last week.

The dispute in the file trade has now been brought to a conclusion, for a period of six months at least. The masters have plenty of orders in hand, but what they are complaining about is the lowness of prices. Now-a-days, from 50 to 67½ per cent. discount is allowed out of Sheffield, according to the size of the files and the quality of steel used. In the opinion of the men the employers ought to knock 2½ per cent. off the discounts, and in this manner compensate themselves for the advance in wages. The masters look at it this way. There are a number of manufacturers who are not members of the union, and those who are in the association must consider before raising their prices, while their rivals continue to allow the old discounts. Efforts having failed to secure uniformity of action in the way of improving prices, there is no doubt that more machinery for producing files will be put down, and the number of file workers gradually decreased.

The cutlery trade is in a fairly active condition. The home demand for table cutlery of the best and medium sorts is well up to the average. Many houses are able to find their men full employment. There is an excellent call for pocket and table cutlery from the continental and colonial markets. Very little business is being transacted with America. A few lines have come in this week, but they are very trifling. This is generally the time of the year when the American business is in full swing; but the fact is being steadily forced upon local houses that the United States market is less and less to be relied upon. In the higher grades of goods, one or two houses can command important work from customers with whom price is no object. In the secondary classes, however, where the lines are the heaviest, the English makers are completely underquoted by the American and German makers.

The Manchester, Sheffield, and Lincolnshire Railway Company is making some extensive alterations to its Victoria Station at Sheffield, in view of the completion of the London extension. The citizens have complained for a long time of the need of another entrance to this station. Some time ago a deputation waited on the directors, and received assurances that the station would be enlarged and improved before long. The management have now decided to make a new entrance in Sussex-street. There will be an inclined way from the street, up to which vehicles may drive. A double subway is to be built—one division for passengers and the other for luggage, connected with the platforms by flights of steps and hoists for the luggage. Access to the new approach from the north-east will be easy, but the intervention of the river Don between Sussex-street and the Wicker will be very awkward for citizens who live on the north-west side. It is proposed to build a bridge over the Don, and several other alterations will have to be made before the new approach can be fully used. The internal improvements at the station include the provision of a new platform, a new line for passenger traffic, and the extension of the existing bays. The aggregate result will be that the platform area will be increased from 3980 square yards to 7598 square yards. The cost of the enlargement will be about £65,000, without taking into account the value of property and interests which will be absorbed by the scheme.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE Whitsuntide holidays have curtailed business a good deal this week, and nearly all the works, except those producing pig iron, have been idle for one and, in many cases, two days. Though there is still plenty of work on the books of manufacturers, it does not seem to be pressing, and the men, having done well of late, have been ready enough to take the holiday. The tone of the market is satisfactory, and a more active demand is reported by producers in most branches. The situation is more encouraging, and producers and consumers are both more disposed to operate now that labour difficulties have apparently been settled for some time to come. The adjustment of the engineers' dispute has cleared the way, and the market quickly responded when the settlement was announced.

The employers in the engineering industry have been very generous in their treatment of their workmen. Having agreed with the Engineers' Society to abide by the literal wording of their arrangement with the men as to the advance to be given in September, and to pay all the lower class men the same rate of advance as the higher paid men, giving all alike 1s. advance whatever the standard wage, the employers have decided to grant the same privilege to the lower classes of other societies and to non-unionists, giving them 1s. instead of the 6d. heretofore agreed upon. It is stated that while the extra 6d. per week, for which the Amalgamated Society of Engineers contended on behalf of their less skilled men, would not have exceeded £4 per week, taking the whole of the North-east Coast, the present action will involve them in a large extra expenditure; but they felt they were not doing justice to give extra wages to the members of the Engineers' Society, and leave out others occupying a similar status, although these latter were pledged to accept 6d. in September, with the understanding that there should be no further change of wages before March, 1897.

The pig iron trade is somewhat stronger than it has hitherto been this month, and neither sellers nor buyers are so reluctant as they were to enter into contracts. Usually towards the end of the month weak speculators offer cheap lots of iron which they are forced to sell, and this eases the prices, but this month there is little of that, and the tendency of prices is rather towards firmness. As exports of pig iron have not been so brisk this month as they were last month, and local consumption has been reduced by the holidays, it is believed that the consumption for May will barely exceed the production, and there is a probability that there may be an increase in stocks. It would strengthen the position of makers considerably if they blew out three or four furnaces, and especially those producing hematite pig iron. There is a belief that the output of hematite pig iron is much in excess of the requirements, but this cannot be verified, as no record of stock of hematite pig is issued, or even collected. It would be well if the hematite pig iron makers could follow the example of those producing Cleveland iron, and have included in the monthly statistics the stock held of hematite pig. A step towards this has been attained, for Connal's make known what quantity of hematite iron they have in stock. The large make prevents producers from securing the prices they might obtain with a smaller output. Besides this it keeps up their cost of production, as it enables the coke manufacturers to maintain their high prices. Coke is now relatively dearer than pig iron; formerly the Cleveland ironmaster had to pay out for fuel one-third of the price he realised for his pig iron; now the proportion is greater, for while he has to give 13s. 9d. per ton for the coke delivered at his furnaces, he can only get 37s. 6d. for his No. 3 pig iron.

This week the general quotation for No. 3 Cleveland pig iron has been 37s. 6d. per ton for prompt f.o.b. delivery, and in many cases this would also be accepted for June deliveries. Some of the makers are also getting 38s. for next month. Cleveland warrants, which at the end of last week were quoted at 37s. 9d. cash by holders, and which buyers would purchase at 37s. 8d. cash, could on Tuesday be bought at 37s. 4½d., and Wednesday's closing price was at 37s. 2d. The stock of Cleveland pig iron held by Messrs. Connal and Co., on Wednesday night was 198,124 tons, or 4368 tons increase this month. No. 1 Cleveland pig iron has been bought more freely this month, but nevertheless compared with No. 3 it is at a low price. It was 2s. 6d. per ton dearer than No. 3, now not more than 1s. 3d. parts them, and continental consumers, who used to be the chief buyers of it, take comparatively little now, as they find that No. 3 answers their requirements equally as well. No. 4 foundry pig iron is at 36s. 9d., grey forge at 36s. 3d., and white at 36s. M. Nos. of Cleveland hematite pig iron are to be bought at 45s. 9d. per ton for early delivery, though the leading makers hold out for 46s. This is a good deal more than the nominal price of Cleveland hematite warrants, but no one seems to care to buy the latter, as a purchaser does not know what brands he may get, and he prefers to have a known brand, the analysis of which is guaranteed to him.

The finished iron mills and forges are fairly well off for work, but almost all were idle on Monday and Tuesday. Just now the demand is generally slack, but on the whole prospects are more favourable than they were, now that the engineers' strikes are over, and trade is likely to be less uncertain. The shareholders of the Darlington Steel and Iron Company, whose works have been idle since October, 1894, and who formerly were occupied chiefly in producing steel rails, hold their annual meeting this week, and are called upon to discuss whether the works are to be reopened or the company is to be wound up. The directors have consulted Mr. Kean, who was formerly engineer to the company, and he states that before the works could be restarted at least £27,905 would have to be spent upon extensions and improvements. A new cogging mill would be needed with engine, live roller gear, &c.; a new 12in. mill for fish-plates; new engine for 15in. mill; new boilers over furnaces, to utilise the waste heat; new cold sawing machine, &c. The directors think that to provide for contingencies, £30,000 should be taken for these improvements, &c. Then £11,000 should be found for working capital, and £14,000 to pay off the mortgage on the works; altogether, £55,000 would have to be provided by the shareholders to reopen the works. If the shareholders decide on the realisation of all the company's assets, it is estimated that the cash investments, movable stocks, and debts, would be sufficient to pay off all the liabilities of the company, leaving the proceeds of the land, buildings, fixed plant, and machinery, together with the tap cinder still lying in the ground available for distribution among the shareholders.

The statistics supplied by Mr. Waterhouse to the Board of Conciliation and Arbitration for the Manufactured Iron and Steel Trades of the North of England, showing the deliveries and average realised prices of finished iron in the district during March and April, are not satisfactory, seeing that a decrease in the realised price is reported where an increase was expected, as quoted prices were higher than in the previous two months. It is evident from the returns that the improvement has benefited the manufacturers in giving them more work but not any better prices; in fact, they have generally not got the higher prices which they asked, and especially is this the case with bars, which form 46 per cent. of the production. The net average realised price for all kinds of manufactured iron was £4 16s. 0·21d. per ton, this being 7·68d. per ton below the previous return, and 2·48d. below the figure for the last two months of last year. The wages at the mills and forges in the North of England will therefore remain unaltered for June and July. Iron rails, which form about 2 per cent. of the production, declined 9·46d. in value; and bars fell 1s. 6·65d., which is rather surprising. Angles went up 2·12d., and plates 0·19d. The deliveries, however, were better by 20 per cent. than in the previous two months, and this notwithstanding that the Easter holidays occurred in the last two months. The following is the official return for the two months:—

Description.	Weight invoiced.				Percentage of total.	Average net selling price per ton.		
	tons	cwt.	qr.	lb.		£	s.	d.
Rails..	533	17	3	9	2·18	4	8	6·47
Plates	9,492	2	1	20	38·72	4	13	7·18
Bars	11,347	7	1	14	46·29	4	18	10 74
Angles	3,140	15	2	22	12·81	4	14	2·39
	24,514	3	1	9	100 00	4	16	0 21

Considerable activity is reported in the demand for castings, and ironfounders and engineers are as a rule doing well as regards the number of orders they secure, but they have not been able to raise prices materially as yet. It is reported that Messrs. Head, Wrightson, and Co., Teesdale Iron and Engineering Works, Thornaby-on-Tees, have found that with their present plant they are not able to overtake their orders, and they have therefore leased the Eaglescliffe Foundry, near Stockton, which was established by Messrs. Smith and Stoker, but has been idle for several years.

The coal trade is comparatively quiet in all branches, partly because of the holidays, but in addition the rush of demand from the Continent for steam coal has subsided, and some firms will sell best Northumberland steam coal at 8s. per ton f.o.b., whereas 8s. 3d. was the regular price last week. Best Durham gas coals are at 6s. 6d. per ton f.o.b. The supply of coke is no longer short of the requirements, and 14s. per ton delivered at Middlesbrough furnaces can no longer be got, except for the "tip-top" qualities; the regular price being 13s. 9d. Nearly every available coke oven in Durham is at work.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE pig iron market was closed on Monday as well as several days last week, and since its re-opening the tone has been weak, with a considerable quantity of iron being offered, the result being that prices have receded. It is usual after a holiday that the market prices up, and the fact that it has not done so on this occasion is regarded as evidence that consumers had already secured pretty large supplies, and are not very apprehensive of a rise in prices. Business has been done in Scotch warrants from 46s. 11d. to 46s. 5d. cash, and 47s. 0½d. to 46s. 7½d. one month. The transactions in Cleveland iron were for the most part for future delivery, and the prices have been from 37s. 10d. to 37s. 6d. one month. Hematite iron has been quiet and easier in the open market. Cumberland warrants have varied from 47s. 8½d. to 47s. 4d. cash, and 47s. 11d. to 47s. 6d. for one month.

The output of Scotch pig iron is well maintained. There are 40 furnaces producing ordinary, 38 hematite, and 3 basic iron, the total of 81 comparing with 82 in the preceding week, and 76 at this time last year. The consumption of Scotch-made hematite pigs is greater than at any former time, notwithstanding that the imports of English iron of this district are much larger than the average. In order to provide for an increased continuous supply of hematite ore, some large contracts have been entered into with merchants in the Spanish trade, while ironmasters who have mines of their own in Spain are chartering considerable numbers of steamers to bring ore into the Clyde. The present rate of freight is about 5s. 4½d. per ton.

Since last week there has been comparatively little change in stocks of pig. They have not been increasing, it is thought, to any appreciable extent. Indeed, the pig iron in Glasgow warrant stores show a slight decrease compared with the preceding week.

The prices of Scotch makers' pig iron are as follows:—Govan, Monkland, and Carnbroe, Nos. 1, 47s. 6d.; Nos. 3, 46s.; Clyde, No. 1, 50s.; No. 3, 47s.; Gartsherrie, Calder, and Summerlee, Nos. 1, 50s. 6d.; Nos. 3, 48s.; Coltness, No. 1, 53s.; No. 3, 48s. 6d.; Glengarnock at Ardrossan, No. 1, 50s.; No. 3, 45s. 6d.; Eglinton, No. 1, 47s.; No. 3, 45s.; Dalmellington at Ayr, No. 1, 46s. 6d.; No. 3, 44s. 6d.; Shotts at Leith, No. 1, 52s.; No. 3, 48s. 6d.; Carron at Grangemouth, No. 1, 52s. 6d.; No. 3, 48s. 6d.

The shipments of pig iron from Scottish ports in the past week amounted to 5023 tons, against 4712 in the corresponding week of last year. There was despatched to Germany 600 tons, United States 220, South America 375, India 122, Australia 111, France 25, Italy 190, Belgium 980, Spain and Portugal 70, China and Japan 100, other countries 25, the coastwise shipments being 2205 tons, compared with 1902 in the same week of last year.

The finished iron department is well employed, and prices are fairly steady. In the steel trade there is a continuance of the great activity so frequently noticed already. The locomotive engineers are full of work, having contracts on hand that will keep them going for a long time to come. Numerous other branches, among them being the cycle industry, which is exceptionally active, are now experiencing a period of improved trade.

There is little change in the position of the coal trade, but such as there is appears to be in a favourable direction. The coal shipments at the Scottish ports amount to 167,647 tons for the week, against 153,733 in the preceding week, and 146,288 in the corresponding week of last year. There is a fairly good market for household coals of the better qualities, and furnace coals and dross are in good request, but the supply is still more than equal to all requirements. Main coal is quoted f.o.b. at Glasgow 5s. 9d.; splint, 6s. 3d. to 6s. 6d.; ell, 6s. 3d. to 6s. 9d.; steam, 7s. 6d. per ton.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

A GOOD bulk of work was done in the coal trade in the week previous to the holidays, but since then the usual Whitsuntide slackness at docks and on the Exchange has been very perceptible. Even by mid-week the attendance was of a very lukewarm character, and the week promises to be of the old type—little work, with a good deal of holiday and excursion character about it.

As indicating the pressure of last week, I may note that Cardiff coal exports totalled the high figures of 355,000 tons, or 26,000 tons more than the total of the previous week. Newport total was 68,339 tons coastwise and foreign, and Swansea 35,971 tons. The total dock business at Swansea exceeded that of the previous week by 20,000 tons. The Swansea coal shipments included 12,625 tons to France, 1570 tons to Germany, 2500 tons to Cape Town, 2710 tons to Portland (O.), 4000 tons to San Francisco, and 1050 tons to Australia. The item to Germany is somewhat of a comment upon recent suggestions that Germany contemplates flooding the London market with Westphalian coals. In Welsh coal circles it is contended that, even if the German collier works at 40 per cent. less wages than the Welsh collier, there is no fear of successful competition with Wales so long as the Welsh labour market is tranquil. With pits closed in Wales will come the German opportunity.

The colliery questions of the Aberdare, Hirwain, and Merthyr districts are taking more hopeful form. Bwllfa has acquired the Nantmelin Colliery, and will work it in conjunction with that of Pwll Alse. As regards Aberdare—Merthyr, at Hirwain, this is a trifold royalty, the Bute, Crawshay, and Gwyn Holford. It is thought that this may be acquired and worked by the Bute. The Plymouth Colliery question has now been before the arbitrator, and is progressing satisfactorily.

Mid-week's quotations, Cardiff Exchange, showed little or no change; and the business done was only formal. Prices remain much about the same: Best steam, 10s. 3d. to 10s. 6d.; best seconds, 9s. 9d. to 10s.; ordinary seconds, 9s. 3d. to 9s. 6d.; dry, 8s. 7½d. to 8s. 10½d.; best Monmouthshire, 8s. 3d. to 8s. 6d., seconds, 7s. 9d. to 8s., shipment at Cardiff, but when shipped at Newport, Mon., 3d. per ton less. Best small steam, 4s. 9d.; next best, 4s. 3d. to 4s. 6d.; seconds, 4s.; drys, from 3s. 6d. House coal is, as usual, quiet. Prices:—9s. 6d. to 10s.; No. 3 Rhondda, 9s. 6d. to 9s. 7½d.; brush, 7s. 9d. to 8s.; small, 6s. 3d. to 6s. 6d.; No. 2, Rhondda, 7s. 3d. to 7s. 9d.; through, 6s. to 6s. 3d.; small, 4s. 3d. to 4s. 6d.

Swansea prices:—Best anthracite, 11s. to 11s. 6d.; second quality, 9s. to 10s.; ordinary large, according to quality and selection, 8s. to 8s. 9d.; small supply culm, 4s. to 4s. 6d. Steam coals, 9s. to 10s.; seconds, 8s. 3d. to 9s.; bunkers, 7s. to 9s.; small, 4s. 3d. to 4s. 6d., f.o.b. Swansea, cash thirty days, less 2½. Bituminous coals, No. 3 Rhondda, 9s. 6d. to 10s.; No. 2 Rhondda, from 8s. 6d.

Coke not only maintains past quotations, but makers are adding a few pence more per ton. Last prices are furnace, 13s. to 14s. 9d.; foundry, 15s. 6d. to 16s. 9d.; special foundry, 19s. 6d., Cardiff. Increased vitality is showing itself in the pitwood trade, and quotations are firm at 16s. to 16s. 3d. Patent fuel, 9s. 9d. to 10s. 3d.; moderate demand, Cardiff and Swansea.

At Briton Ferry Cambrian coke is reported in great demand.

As might be anticipated, there is very little moving in the freight market. At Cardiff, mid-week, the only outward fixtures negotiated were two for Genoa at 6s. 6d. clean, and a homeward fixture from Bilbao to Newport, Mon., at 4s. 7½d.

The revival of the steel rail trade at Cyfarthfa is progressing, one of the first orders being for a rail with wide flange, similar to the rail used on the Rhymney Railway, which requires no sleepers. This is a very difficult article to turn out, compared with the bull-headed pattern, but the Cyfarthfa Company, having attained the front rank in steel, is not likely to raise any objection to the form it takes.

The rail clearances of the past week and the early part of this include 800 tons for Santos from Cardiff, and 500 tons for Freemantle from Swansea.

The principal demand is for steel rails, bars, and small goods, and Swansea works are reported full of orders. I am also glad to note that generally there is better demand for steel bar.

The report from the tin-plate works last week showed an increased make of tin-plate. About half the mills are at work, and makers say that if more are started the result will be depression again, as cost is not even now covered by price. I give the iron and steel and tin-plate quotations ruling at Swansea this week.

Glasgow pig, 46s. 8d.; Middlesbrough, 37s. 6d.; hematite, 45s. 5d.; Welsh bars, £5 10s. to £5 12s. 6d.; iron plates, £6 to £6 17s. 6d. at works. Steel plates, £6 to £6 7s. 6d.; steel rails, £4 10s. to £4 12s. 6d. for heavy; light rails, £5 to £5 10s.; Bessemer steel bars, £3 17s. 6d.; Siemens, £3 18s. Tin-plates, Bessemer coke, 9s. 3d. to 9s. 4½d.; Siemens, 9s. 6d. to 10s.; ternes, 16s. 6d. to 21s. 6d.; best charcoal, 12s. 9d. to 13s.; block tin, £60 7s. 6d. to £60 10s.

Tin-plate still keeps to the front in a large part of the district, and discussions abound as to the ways and means for improving the trade. The advice of Mr. Stanley to "drum up orders in Africa" was simply a re-echo of the capital idea and effort made by the Associated Tin-plate Owners some time ago to find new markets. That failed from a lack of unanimity between makers, and, in some parts, from a dislike to sink money on the artesian well plan, "letting water down to get water up." It is feared that merchants having business centres in Africa would oppose the action of tin-plate manufacturers to find trade themselves—so runs present opinion. In the meanwhile, the trade has not so gloomy an appearance in some districts. Good reports come from Briton Ferry.

An alternative water scheme, which promises most satisfactory results, has been submitted to the Council, Newport, Mon., and a resolution that it should be reported upon was carried. The long drought is beginning to cause a good deal of concern, and pumping back into the Merthyr reservoir is in daily operation. The mountain rivers in many parts of Wales are simply rocky beds. The Wye in many places is drier than I have known it. The Usk river, Brecon, is moderately full. The Taff between Merthyr and Cardiff is only an excuse for a river. Considering that great quantities of water are in the deep coal pits, a systematic pumping in aid of sanitation by keeping a good body of water in the rivers is recommended.

Iron ore has been coming in at a great rate this week, arousing an impression at docks and on lines of route that a boom was on in iron and steel. This is not so, but prospects are more assuring. On Tuesday the imports at Newport from Bilbao included 1900 tons ore for Ebbw Vale and 1800 tons for Blaenavon. The same day Cyfarthfa received three cargoes from Bilbao, Almeria, and Seville, and Dowlais Company three from Bilbao.

One of the principal events of the week has been the announcement that the Bute Docks Company invite subscriptions for £500,000 4 per cent. Preferred Ordinary Stock, this amount being required for making the new dock now in course of construction. The announcement is regarded with peculiar satisfaction, as it is the first time the public have been invited to take shares in the undertaking, the public subscriptions hitherto invited having been confined to the debenture issue. The subscription is fixed at £110 per £100.

Mr. Phillips, M.E., of Pretoria, an old pupil of Sir W. T. Lewis, Bart., died lately.

The Great Western Railway Company has deposited a petition, praying to be heard against the Llanelly Harbour Bill when it comes before the Select Committee.

It is likely that Mr. Clarke, present assistant-secretary Taff Vale, will be the permanent secretary, vice Mr. J. Jones deceased.

Some interesting figures are recorded of Newport trade in '95:—6904 steamers and ships cleared. Only ninety of these were foreign vessels. Their united tonnage was 1,298,085. Italy was Newport's best customer, France second, Spain third.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

ACTIVITY continues to increase on the continental iron markets. Since last week no material changes have taken place with regard to prices, which are as a rule tending upwards.

The iron trade in Silesia is in a most satisfactory condition, and promises to be even more active in a few weeks. All round the outlook is bright, and an exceedingly firm tone prevails in the various departments; the volume of business is gradually swelling, and the mills and forges are all full of work.

On the Austro-Hungarian iron market only a moderate weight of new business is reported to have come forward during the past week, but makers, having their order books pretty well filled, hold firmly to their prices. Only foundry pig has of late been a trifle weak in demand, and quotations were fluctuating. For plates, and also for various articles of finished iron, a regular, healthy inquiry has been experiened.

Satisfaction is universally expressed with regard to the present state of the French iron industry, most of the establishments being as full of work as they can well be. Makers have resolved to desist from a further rise in prices for the present, bars standing on 145f. p.t., and girders on 155f. to 160f. p.t. There is talk of several new conventions that are about to be formed; one will be a syndicate of the tube mills. French import in coal during the first quarter of 1896 was 2,163,490 t., against 2,205,470 t. for the same period the year before, 1,182,620 t. coming from England, against 1,095,650 t. in 1895; 824,510 t. from Belgium, against 998,750 t.; 155,210 t. from Germany, against 109,440 t.; while imports from other countries amounted to 1150 t., against 1630 t. in 1895. Imports in coke were 334,830 t., against 359,390 t.; 126,330 t. came from Belgium, against 105,040 t.; 206,020 t. from Germany, against 247,310 t., and 2480 t. were imported from different countries, against 7010 t. in 1895. Exports in coal were 212,280 t., against 185,130 t. in the year before; of these 104,690 t. were sent to Belgium, against 97,980 t.; 61,030 t. went to Switzerland, against 49,800 t.; 3460 t. were exported to Italy, against 3690 t.; 3208 t. to Algiers, against 210 t.; 820 t. to Turkey, against 2670 t., and 38,810 t. to other countries, against 28,880 t. in the same quarter last year. French export in coke amounted to 14,340 t., against 31,810 t. in 1895.

Reports from the Belgian iron market are such as to create a favourable impression with regard to the future condition of the iron and steel industries. Especially the business that is done on home account must be considered as good. Export trade is less satisfactory, although an improvement in demand has certainly taken place; but makers find it exceedingly difficult to sell their articles at the official rates. Prices in April were, for foundry pig No. 3, 53f. p.t.; forge pig, 49f. to 50f. p.t.; bars, No. 2 f.B.t., stood on 137·50f. p.t. on May 1st, against 132·50f. on April 1st; No. 3 fetches 142·50f. p.t., against 137·50f. p.t.; girders No. 2, for home demand, rose from 130f. p.t. on 135f. p.t.; angles, from 137·50f. p.t. on 145f. p.t.; plates No. 4, for export, advanced from 180f. on 185f. p.t.; No. 2, for inland demand, rose from 145f. p.t. on 147·50f p.t.; No. 3, from 155f. on 157·50f. p.t.; steel plates rose from 155f. on 157f. p.t. Sheets advanced from 165f. on 167·50f. p.t. For export steel plates are now quoted 150f. p.t., against 145 in the beginning of April. The number of blast furnaces in Belgium has considerably increased in April. On May 1st there were thirty-one furnaces in blow, out of forty-two built, eleven producing forge pig, four foundry pig, and sixteen basic. Output of pig iron in Belgium was for April of present year, and during the first four months of 1896 and 1895, as under:—

	April.		January 1st till May 1st.	
	1896.	1895.	1896.	1895.
	Tons.	Tons.	Tons.	Tons.
Forge pig ..	25,350	38,595	101,145	148,395
Foundry pig	6,900	8,990	28,225	35,090
Basic	34,500	33,790	139,150	120,690
Total ..	66,750	81,375	268,520	304,175

The Belgian coal market has not in any way changed since previous reports, nor is there likely to be an improvement in the immediate future, prices being firm at date; but there are only very few contracts offering. Engine classes of fuel are specially languid. Best steam coal is sold at 10f. to 11·25f. p.t.; dry kinds, 6·75f. p.t.; seconds, 8f. to 9f. p.t. Here and there inquiries for house coal have already been coming in for next winter, and stocks are very low, chiefly on account of the cool weather that has prevailed in March and April. Last year's prices are, almost without questioning, accepted for next season, the different sorts of house coal standing on 12f., 15f., 18f., and 22f. p.t.

A steady demand is experienced for coke, prices for next quarter having been fixed on 15f. p.t., and for the remainder of the year 16f. p.t. will be asked. However, producers will have to wait till the beginning or end of next month ere they can ascertain whether these prices can be accepted.

With regard to Belgian business in coal and coke during the first quarter of the present year, there were 401,711 t. coal imported, against 334,261 t. in the year before; 228,499 t. coming from Germany, against 158,622 t. in the previous year. In coke, 51,079 t. were imported, against 92,545 t. last year; 47,142 t. coming from Germany, against 91,055 t. during the corresponding period last year. Export in coal amounted to 1,009,112 t., against 1,196,127 t. Of these 49,410 t. were sent to Germany, against 71,305 t.; to France 759,146 t. were exported, against 938,766 t. during the same period the year before. Export in coke was 205,941 t., against 221,229 t., of which 23,720 t. were sent to Germany, against 38,841 t., while to France 122,367 t. were exported, against 94,754 t. for the corresponding period last year.

There is no abatement of activity in the producing and manufacturing branches of the Rhenish-Westphalian iron and steel industry. A comparatively large amount of new work has been offering, and prices have gained in firmness, but are officially the same as during former weeks. Iron ore continues strongly inquired for, especially the Siegerland sorts are brisk of sale, while the demand for Nassau iron ore has been just a trifle less active than formerly. Quotations are, for spathose iron ore, M. 9 to 9·60 p.t.; roasted ditto, M. 12 to 13 p.t.; calcined iron ore, M. 12 to 14 p.t. at mines. Nassau red iron ore, 50 per cent. contents, M. 9·70 p.t., free Dollenburg. Luxemburg and Lorraine minette has of late been a trifle more weak in quotations; as a rule M. 2·40, 2·70, and 3·20 p.t. is asked, At the blast furnace works a good activity continues, and prices are satisfactory on the whole. Spiegeleisen, 10 to 12 per cent. grade, is offering at M. 59 p.t.; forge pig, No. 1, M. 53 to 55 p.t.; No. 3, M. 42 p.t.; hematite, M. 65 p.t.; foundry pig, N. 1, M. 65 p.t.; No. 3, 57 p.t.; basic, M. 56 p.t. at works; Bessemer, M. 60 p.t.; iron for steel making, M. 54 to 56 p.t. at works. Luxemburg foundry is quoted 56f. p.t., free Luxemburg. Output of pig iron in the Saar district was, for April and during the first four months of present year, as under:—

April.		January 1st till May 1st.	
1896.	1895.	1896.	1895.
99,836 t.	93,878 t.	395,987 t.	367,529 t.

In the manufactured iron industry trade continues in the satisfactory condition previously reported. Bars are actively called for, and so are girders, quotations showing much firmness. Plates of all descriptions are also readily consumed, and the employment of the sheet mills is improving from week to week. The condition of the wire trade is unmistakeably better than it was a month ago, and if prices do not rise, they are, at least, exceedingly firm. Foundries, machine, and wagon factories are all in good occupations.

Present list prices, per ton at works, are as follows:—Good merchant bars, M. 120; angles, M. 130; girders, M. 94 to 97; hoops, M. 120 to 125; billets in basic and Bessemer, M. 85 to 86; heavy plates, for boiler-making purposes, M. 160 to 165; tank plates, M. 135 to 140; steel plates, M. 145; tank plates, M. 120 to 125; sheets, M. 155 to 160; iron wire rods, common quality, M. 125 to 130; drawn wire in iron or steel, M. 118 to 138; wire nails, M. 127 to 130; rivet iron, M. 138; rivets, M. 180; complete sets of wheels and axles, M. 280 to 290; axles, M. 220; steel tires, M. 200; steel rails, M. 118; steel sleepers, M. 110; fish-plates, M. 120 to 130; light section rails, M. 100.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

THE shipments of steam coal for the past week were fully up to the average, and the present demand is good, with quotations unchanged. The house coal trade is good for this season of the year. Tin-plates without alteration in prices or demand. The iron and steel works continue well employed.

Coal: Best steam, 8s. 3d. to 8s. 6d.; seconds, 7s. 9d. to 8s.; house coal, best, 9s. 9d. to 10s.; dock screenings, 5s.; colliery small, 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 46s. 5d.; hematite warrants, 47s. 3d. f.o.b. Cumberland; Middlesbrough No. 3, 37s. 2d. prompt; Middlesbrough hematite, 44s. 10d. Iron ore: Rubio, 12s.; Tafna, 11s. 3d. Steel: Rails, heavy sections, £4 12s. 6d.; light ditto, £5 f.o.b.; Bessemer steel tin-plate bars, £4; Siemens tin-plate bars, best, £4 2s. 6d.; all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel, coke, 9s. to 9s. 3d.; Siemens, coke finish, 9s. 3d. to 9s. 6d.; ternes, per double box, 28 by 20 C, 18s. 6d. to 20s. Pitwood: 15s. 9d. to 16s. London Exchange Telegram: Copper, £47 8s. 9d.; Straits tin, £60 10s. Freights firm.

KING'S COLLEGE ENGINEERING SOCIETY.—At a general meeting, with the president in the chair, Mr. Simpson read a paper on "The Blackwall Tunnel." The author pointed out the various causes which culminated in "the origin of the scheme." He then went on to describe the shafts sunk, enumerating them, and the different strata encountered in sinking them. The difficulties met with due to loose sandy and water bearing strata, especially in shafts 3 and 2, and the methods resorted to in order to overcome such difficulties, were all clearly explained. The next prominent feature dealt with was the shield, which, with hydraulic fittings, use, strength, method of working, and pressure required in this case to work it, formed an exceedingly instructive part of the paper. The way in which the shield was got on the scene of action at the foot of the shaft—by filling the shaft with water and floating shield down by pumping out the water; the costly and fatal accident to the cutting edge of the shield and the manner in which this was repaired, were all well explained. The author then considered the manner in which the external face of the cast iron segments of the arch were cased with cement—by grouting, the pneumatic arrangement for forcing the grout behind being illustrated by a diagram. The part worked under compressed air, the air locks, and arrangements for preserving the workmen in case of the heading flooding, were thoroughly and clearly dealt with. Messrs. Fletcher, Standen, Strutt, Mowat, and Bailey joined in the discussion which followed. The meeting terminated with a vote of thanks to Mr. Simpson for his exceedingly interesting paper.

10,265. Ship Frames, M. H. C. and R. E. C. Shann, London.
10,266. Internal Combustion Engines, S. O. Cowper-Coles, London.
10,267. Electrodes for Galvanic Batteries, C. Hoepfner, London.
10,268. Pneumatic Tires, G. Nivet, London.
10,269. Self-propelling Cycles, &c., R. O. Allsop, London.
10,270. Collars, V. Drew, London.
10,271. Removing Dust from Cushions, J. E. Howard and J. C. Taite, London.
10,272. Dynamo-electric Machines, H. T. Harrison, London.
10,273. Catamenial Bandages, S. Drucker, London.
10,274. Device for Cleaning Slates, W. G. Hill, London.
10,275. Candlesticks, C. Cox, London.
10,276. Book Forms of Kinetoscopes, H. W. Short, London.
10,277. Cycle Pneumatic Tire Ball, W. Meadows, London.

14th May, 1896.

10,278. Rain-water Separator, S. Skinner, Hastings.
10,279. Cycle Tires, C. E. Taylor, L. B. Taylor, and C. F. Gray, Birmingham.
10,280. Horizontal Windmills, J. W. Cooper, Southampton.
10,281. Axles for Driving Cycles, W. G. Armstrong, London.
10,282. An Oscillating Tower, A. H. Tyler, London.
10,283. Road Locomotive Engines, H. Knowles, Liverpool.
10,284. Glow Lamps for Electrical Lighting, G. W. Pridmore, T. J. Sturgeon, and E. Yorke, London.
10,285. Lavatory Basins and Baths, F. C. Lynde, Manchester.
10,286. Rotary Engines, G. W. Hart, Nottingham.
10,287. Luggage Carrier for Cycles, T. Rosethorn, Manchester.
10,288. Straight Swell for Looms, R. Wilde, Stalyridge.
10,289. Cycle Lamps, J. Parker, C. Hudson, and J. H. Smith, Birmingham.
10,290. Penholder and Ink Container, E. A. O. Leeds, Birmingham.
10,291. Draw Plate for Fire-grates, E. A. O. Leeds, Birmingham.
10,292. Sweeping Chimneys, M. H. Barlow-Massicks, London.
10,293. Fire-bricks, J. G., T. E. W., and R. O. Henry, Newcastle-on-Tyne.
10,294. Heating Feed-water, D. Rushworth, Stockport.
10,295. Lids of Saucepans, &c., E. Eyre, Sheffield.
10,296. Bolts for Doors, E. Harrison and W. A. Lathbury, Birmingham.
10,297. Box for Potted Meat, A. Gruner and W. Cooby, London.
10,298. Music Stands or Desks, J. McL. Whitfield, Huddersfield.
10,299. Tipping Soap Dish or Holder, J. Harrison, Leeds.
10,300. Golf Clubs, J. Leigh and J. A. Penny, Manchester.
10,301. Buffers, &c., for Windows, G. Cotton, Nantwich.
10,302. Dye Sticks of Dyeing Machines, B. L. and E. Fletcher, Halifax.
10,303. Self-propelled Vehicles, J. H. Hamilton and A. Rollason, Nottingham.
10,304. Leather Tires for Cycles, J. B. Fenby, Birmingham.
10,305. Grinding Chalk, T. C. Fawcett, Ltd., T. C. Fawcett, and J. D. Fawcett, Halifax.
10,306. Cycles, J. Wallace, jun., Belfast.
10,307. Gas Engines, J. P. Binns and H. G. Binns, Luddenden.
10,308. Reflector for Affixing to Educational Blackboard, W. T. Tutton, Shrewsbury.
10,309. Frames of Cycles, &c., G. Barker, Sutton Coldfield.
10,310. Wheel Tires for Cycles, J. M. Meech, Brighton.
10,311. Greasing the Axles of Coal Tubs, F. A. Murphy, Oldham.
10,312. Automatic Feed-water Regulators, R. B. Smith, Birkenhead.
10,313. Metallic Packings, J. Butterworth and R. F. C. Tonge, Manchester.
10,314. Bands for Driving Machinery, J. Wetherill and W. J. Armitage, London.
10,315. Floor Coverings, J. Wetherill and W. J. Armitage, London.
10,316. Windows of Vehicles, W. Perrins, Birmingham.
10,317. Toy, C. W. Hunter, Hull.
10,318. "The Hare Axle Cushion" for Cycles, G. F. Hare, Limerick.
10,319. Nut Lock for Bolts in Wood, J. T. Sanders and W. H. Nott, London.
10,320. Nut Lock for Bolts, J. T. Sanders and W. H. Nott, London.
10,321. Nut Lock and Bolt, J. T. Sanders and W. H. Nott, London.
10,322. Nut Lock and Bolt, J. T. Sanders and W. H. Nott, London.
10,323. Boots, F. and C. F. Mobbs, London.
10,324. Carriage and Cycle Tire, W. Merritt, London.
10,325. Velocipedes and other Vehicles, J. J. Rowley, London.
10,326. Sewing Machines, J. Thomas, London.
10,327. Watch Chains and Guards, E. G. Johnson, London.
10,328. Rubber Tires for Cycles, J. Hamilton, London.
10,329. Elastic Tires, H. de Laspée, London.
10,330. Extracting Starch, C. Friedheim and A. Rosenheim, London.
10,331. Wenham Gas Lamps, S. H. Robinson, London.
10,332. Skirt Holder for Lady Cyclist, E. C. Woolmer, London.
10,333. Can Packer, G. A. Farini, London.
10,334. Can Lifter, G. A. Farini, London.
10.335. Box Filler, G. A. Farini, London.
10,336. Flying Toy Bird, J. Nesbit and A. Behrend, London.
10,337. Cycle Adjustable Handle Bars, T. H. Burton, London.
10,338. Tube or Vaporising Element, V. C. J. Ortmans, London.
10,339. Boots, R. McKay, London.
10,340. Cycle Tires, A. E. Mavor and W. Jones, London.
10,341. Cycle Tires, A. E. Mavor and W. Jones, London.
10,342. Disintegration of Quartz, &c., A. Gutensohn, London.
10,343. Packing Tea in Packets, A. V. Smith, London.
10,344. Spring Seats and Backs for Chairs, J. Compin, London.
10,345. Stopping Apparatus for Road Carriages, W. Woolidge, Southampton.
10,346. Dwarf Portable Music Receptacle, R. J. King, London.
10,347. Gear, G. Dallison and C. Pardoe, London.
10,348. Applying Adhesive Substances to Paper, H. E. Smyser, London.
10,349. Preparing Metals for Galvanic Purposes, A. M. Clark, London.
10,350. Elastic Tires, T. E. Wheeler and G. F. Baker, London.
10,351. Checking the Receipts of Bills, A. E. Hodder and J. B. G. Lester, London.
10,352. Corsets, H. Bendy, London.
10,353. Manufacture of Tubes for Cycle Frames, C. Binks, London.
10,354. Chain Geared Cycles, W. W. Ward, Liverpool.
10,355. Velocipedes, W. Hall and P. Leonard, Liverpool.
10,356. Curtain Hooks, E. Blossom, Liverpool.
10,357. Packing and Measuring Embroidery, L. Reichenbach, Liverpool.
10,358. Registering Electric Currents, H. Carbonnellf, Liverpool.
10,359. Fastenings for Retort Lids, &c., W. W. Box, London.
10,360. Bicycles, N. A. Aubertin and C. E. Haverly, London.
10,361. Bicycles, J. L. Souhami, London.
10,362. Wheel Tires, A. H. Bogle, London.
10,363. Box for Containing Paper, H. A. Péraut, London.
10,364. Ticket Pin, H. A. Péraut, London.
10,365. Checking, &c., Apparatus for Billiards, J. G. Dixon, London.
10,366. Books for Cigarette Papers, J. O. Schweitzer, London.
10,367. Boot Trees or Stretchers, P. J. Parmiter, London.
10,368. Surveying Instruments, Elliott Brothers, London.
10,369. Driving Chains for Cycles, J. W. Deans and W. D. and R. J. Foster, London.
10,370. Supports for Attachment to Bicycles, F. C. Yeo, London.
10,371. Boots, C. W. Braithwaite, London.
10,372. Apparatus for Production of Ozone, E. Andreoli, London.
10,373. Fore-carriages, F. J. J. Gibbons, London.
10,374. Star Wheels of Linotype Machines, The Linotype Company, Ld., and J. Place, London.
10,375. Threading Needles, A. and R. Schlagintweit, London.
10,376. Handles for Cycles, J. McRae, London.
10,377. Shoes, R. Hertzberg, London.
10,378. Musical Instrument, A. R. Breinl, London.
10,379. Attaching Venetian Blind Tapes, A. Cameron and H. E. Skinner, London.
10,380. Air Pump for Cycle Tire Tubes, F. E. Bunting, London.
10,381. Horse Provender Receptacles, L. Giese, London.
10,382. Hat Cord Attachments, C. Scheidereiter. London.
10,383. Wheels for Cycles, A. Walter, London.
10,384. Cooling the Cylinders of Engines, F. R. Simms, London.
10,385. Cooling the Explosion Cylinders of Engines, F. R. Simms, London.
10,386. Combined Steering Handles, &c., F. R. Simms, London.
10,387. Pneumatic-tired Wheels, H. Jelley and H. J. Lawson, London.
10,388. Calendars, M. M. Dessau, London.
10,389. Steam Engines, W. B. Crichton, London.
10,390. Tanning Apparatus, A. Levinstein, London.

15th May, 1896.

10,391. Producing Motive Power, D. Cook, London.
10,392. Inflated Tires of Wheels, J. Adair, Waterford.
10,393. Driving Velocipedes, H. T. Scowcroft, Manchester.
10,394. Loom Pickers, J. C. Cartwright, Bradford.
10,395. Supplying Disinfecting Fluids to Water-closets, W. Giddie, Bristol.
10,396. Hat Fastener, W. J. Fox, Manchester.
10,397. Starting Valveless Syphons, L. W. Waechter, Manchester.
10,398. Gear Wheels for Cycles, G. Moore, jun., Birmingham.
10,399. Gas Engines, T. J. Bennett and W. F. Thomas, Birmingham.
10,400. Oil Lamps, J. and A. L. Undy, Derby.
10,401. Billiard Tables, G. Cummings, Blyth.
10,402. Rims and Tires for Wheels, S. Bunting, Birmingham.
10,403. New Explosive, H. Boyd, Birmingham.
10,404. Window Fasteners, T. A. Langhorne and J. Tillotson, Keighley.
10,405. Metallic Lathing, A. R. Fordyce, Manchester.
10,406. Top-pressing Rollers, J. Knowles and J. Robertshaw, Bradford.
10,407. Portable Lamp Standard, R. Goodwin, Dublin.
10,408. Pneumatic Tire Inflators, R. W. Leftwich, London.
10,409. Lubricating Heavy Bearings, J. Lumb, Halifax.
10,410. Guard to Prevent Puncturing of Tires, W. Fletcher, Birmingham.
10,411. Laying Yarns in the Form of Warps, A. Leach, Manchester.
10,412. Velocipede Wheels, J. W. Myers, Whitehaven.
10,413. Compound Fluid Pressure Engines, R. E. Bradford, London.
10,414. Electric Hoists, W. H. Scott, Norwich.
10,415. Electrical Collecting Apparatus, W. Sillery, Wrexham.
10,416. Wheels for Vehicles, F. and A. Mousley, Birmingham.
10,417. Steam Merry-go-round, G. Smith and A. J. Davis, Leicester.
10,418. Door Latch and Lock Combined, E. Hentsch, Nottingham.
10,419. Removing Harness from Carts, S. Cadman, Oldham.
10,420. Draught Preventer for Doors, S. Cadman, Oldham.
10,421. Handle-bars for Cycles, &c., O. Ward, London.
10,422. Pneumatic Tires, H. Jelley and J. Jelley, London.
17,423. Rims for Vehicle Wheels, &c., H. Jelley, London.
10,424. Cooling Surfaces of Cylinders, F. R. Simms, London.
10,425. Independent Washstand, W. H. Wearing, Liverpool.
10,426. Cycle Heads, A. Haskins and C. R. Garrard, London.
10,427. Swaging Machines, W. B. Challen and Taylor and Challen, Ld., London.
10,428. Cycle Parts, C. R. Garrard, London.
10,429. Holders for Electric Lamps, T. R. Kenny, Bradford.
10,430. Cycles, W. J. Giblin, Glasgow.
10,431. Apparatus for Drying Wool, J. Fielden, Rochdale.
10,432. Ladders, J. Malton, Scarborough.
10,433. Propelling and Compressing Fluids, E. Hunt, Glasgow.
10,434. Potato Diggers, T. S. Bisset, Glasgow.
10,435. Combining Oil and Air for Engines, G. Johnston, Glasgow.
10,436. Metallic Packing for Engines, J. Cuthill, Dundee.
10,437. Treating Water, J. T. Norman, London.
10,438. Looms, W. E. Simpson, Birmingham.
10,439. Securing Bottoms of Boxes, M. Heinemann, Birmingham.
10,440. Tires of Cycles and Vehicles, K. Tullis, Glasgow.
10,441. Nursery Safety Pin, K. W. Frost, Birmingham.
10,442. Arc Lamps, W. R. Ridings, Birmingham.
10,443. Pianoforte Practice Board, J. B. Baylis, Southend-on-Sea.
10,444. Constructing Bicycle Frames, F. H. Terry, Birmingham.
10,445. Mandril for Carrying Rollers, H. Meller, Manchester.
10,446. Ships' Rudders, J. M. Ramsay, Glasgow.
10,447. Walking Stick and Field Glass, J. M. Brown, Glasgow.
10,448. Sharpening Reaping Knives, W. French, Glasgow.
10,449. Bicycle Tires, F. Sheridan and A. E. Hodder, London.
10,450. Type-writing Machines, E. W. Hearn, London.
10,451. Velocipedes, A. G. Meeze and S. H. Burchell, Painswick.
10,452. Method of Ringing Cycle Bells, I. Davis, London.
10,453. Pneumatic Tires, O. C. Jones and T. Birkett, Birmingham.
10,454. Bicycles and Tricycles, F. Cooper, Manchester.
10,455. Electric Motors, R. Norman, Eastbourne.
10,456. Electric Motors, R. Norman, Eastbourne.
10,457. Tiles for Roofing Purposes, A. W. Evans, London.
10,458. Protecting Thumb or Finger Nails, E. Nash, London.
10,459. Umbrella Case, J. F. H. V. Hoop, London.
10,460. Cap for Wheels of Road Vehicles, H. Job, Torquay.
10,461. Preventing Tires Puncturing, J. E. Howard, London.
10,462. Manufacture of White Lead, A. Sandiland, London.
10,463. Chain and Wheel, C. Pardoe, London.
10,464. Stretching Hides or Skins, R. Spitz.—(*G. Feith, Austria.*)
10,465. Automotor Carriages, E. Fessard, London.
10,466. Valves for Bottles, T. H. Walker and G. Soar, London.
10,467. Inking Letterpress Rollers, W. Whittaker, Manchester.
10,468. Cycle Saddles, S. Pattisson and F. Mousley, London.
10,469. Button Fasteners, D. Bridgeman-Metchim, London.
10,470. Shaping Nuts, K. Banks and E. N. Banks, London.
10,471. Moulded Clay Articles, &c., W. West, London.
10,472. Material for Secondary Batteries, G. A. Grindle, London.
10,473. Automatic Supply of Water, E. B. Ellington, London.
10,474. Pneumatic Tires for Cycles, J. Brandenberg, London.
10,475. Surgical and Medical Syringes, E. Krüning, London.
10,476. Billiard Cues, A. L. H. Spencer and W. Date, London.
10,477. Metallic Tubing for Bicycles, J. V. Pugh, London.
10,478. Motor Cars, J. C. Merryweather and C. J. W. Jakeman, London.
10,479. Stuffing-box, B. J. B. Mills.—(*H. Rostagnat, France.*)
10,480. Generating Acetylene Gas, P. C. Frewin, London.
10,481. Adjusting Fanlights, G. Deacon, London.
10,482. Attaching Tires to Rims, H. P. Ranger and H. D. Earnes, London.
10,483. Ears for Chamber Pails, &c., J. Fellows, jun., London.
10,484. Tool Holder, H. M. Judd and G. Rushworth, London.
10,485. Oil Feeders, J. Watson and F. G. Brown, London.
10,486. Piston Rings, G. Henderson and T. Hindson, London.
10,487. Smoking Carriages, &c., J. Edwards, London.
10,488. Sand Machines, H. W. Clarke and J. Emery, London.
10,489. Brake for Velocipedes, N. A. Aubertin, London.
10,490. Bottles, R. S. Seaman, London.
10,491. Devices for Holding Cards, H. A. Sieghörtner, London.
10,492. Supports for Trolley Cars, &c., O. Holz, London.
10,493. Tires, H. F. Lange and F. von Leicht, London.
10,494. Extraction of Zinc, J. R. Wylde, J. W. Kynaston, and J. Brock, London.
10,495. Lenses for Photographing, W. Friese-Greene, London.
10,496. Envelopes, W. P. Thompson.—(*D. Conrad, United States.*)
10,497. Electric Traction, J. Perry and T. Tomlinson, London.
10,498. Brakes for Soft Tired Wheels, W. H. Hallett, Liverpool.
10,499. Chain Wheel Mechanism, J. W. Brereton, Birmingham.
10,500. Devices for Velocipedes, H. D. Martin, London.
10,501. Central Buffers and Couplings, G. Johnston, Liverpool.

10,502. Wickless Cooking Lamp, C. E. Ostlund, London.
10,503. Driving Gear for Cycles, T. E. Nightingale, Liverpool.
10,504. Pianofortes, H. J. Brinsmead, London.
10,505. Metallic Packings, W. A. Bennett, London.
10,506. Pneumatic Tires, G. J. Stevens and J. Hix, London.
10,507. Lathe Motion for Looms, G. Schwaabe, London.
10,508. Temperature of Fluids, F. Lamplough and the Automatic Heat Regulator Company Limited, London.
10,509. Reamer, J. A. Little, London.
10,510. Ventilators and Chimney Cowl, J. G. Jennings, London.
10,511. Loading Trucks, W. H. Munns.—(*G. T. Dixon and A. Jamieson, United States.*)
10,512. Leather Belting Apparatus, E. F. Sargeant, London.
10,513. Paving Floors, Landings, &c., P. Stuart, London.
10,514. Seats, J. W. Wightman, London.
10,515. Railway Vehicles, E. J. Pennington, London.
10,516. Bottles, J. G. Henrich, London.
10,517. Bicycles, E. Murray, London.
10,518. Lenses for Photographic Purposes, R. Krügener, London.
10,519. Cushion Noiseless Tire, &c., J. H. Glew, London.

16th May, 1896.

10,520. Fastening Pneumatic Tires, L. O. Michael, Birmingham.
10,521. Sewing Machines, J. Forbes, Tyrone.
10,522. Regulating the Infusion of Tea, T. M. S. Bloxam, Gloucester.
10,523. Transmitting Rotary Motion, E. K. Dutton, Harrowgate.
10,524. Manœuvring of Ships, F. H. and F. H. Pellew, Bristol.
10,525. Bicycle, S. Cooper, Oldham.
10,526. Rims for Wheels of Vehicles, J. Birtwisle, Manchester.
10,527. Preparing Propulsive Powders for Cartridge Cases, C. O. Lundholm, Glasgow.
10,528. Producing Effects, S. Tozer and W. C. Bearder, Nottingham.
10,529. Transverse Mechanism, A. Kay.—(*W. R. Parkin, United States.*)
10,530. Repairing Pneumatic Tires, W. J. Walford, Bristol.
10,531. Securing Pneumatic Tires, A. Hamilton, Dublin.
10,532. Kilns for Burning Cement, P. J. Neate, Rochester.
10,533. Manufacture of Slippers, H. F. Sexton, Norwich.
10,534. A Self-righting Spur, &c., J. Maddock, Burslem.
10,535. Dressing Machine for Yarn, W. B. Soman, Manchester.
10,536. Rulers, R. W. Hodgson, Newcastle-on-Tyne.
10,537. Forming Bodies of Metal Cans, H. Austin, Wolverhampton.
10,538. Air Pumping Apparatus, J. Woodley and W. B. Griffiths, Cardiff.
10,539. Car Couplings, R. C. Sayer, Bristol.
10,540. Air Pump Receiver, A. R. Bennett and C. F. Casella, London.
10,541. Glass Fronts for Buildings, F. S. Rippingille, London.
10,542. Tip Carts or Vehicles, J. and G. Smith, London.
10,543. Fastening Bale Ties and Bands, W. Hayward, sen., Wolverhampton.
10,544. Shoe for Animals, H. J. Tremellen, Newport, Mon.
10,545. Earthenware Scale Plates, G. Herbert, London.
10,546. Pneumatic Tires for Cycles, W. Briscall, Liverpool.
10,547. Disc Valves for Gases, &c., C. H. C. Rudd, Newcastle-on-Tyne.
10,548. Bicycles, J. Price, H. W. Fisher, and N. Collier, Derby.
10,549. File, A. E. Walker, London.
10,550. Filling Oil Tins, D. S. Cargill.—(*The Burmah Oil Co., Burmah.*)
10,551. Picture Suspender, A. V. Ingall, Birmingham.
10,552. Additions to Urinals, T. W. Twyford, Birmingham.
10,553. Furnace Grate-bars, W. Furness and W. J. Bell, Halifax.
10,554. Billiard Cues, H. Externest, jun., Liverpool.
10,555. Purifying Material for Beer, W. P. Knight and E. Cave, London.
10,556. Connecting Cranks to Axles of Cycles, J. Gibson, Manchester.
10,557. Connecting Straps to Vehicles, F. T. Burgess, Bristol.
10,558. Fastenings for Garments, T. P. Taylor, Bristol.
10,559. Pneumatic Billiard Cushions, A. Sydenham and E. J. White, Birmingham.
10,560. Music Stands for Pianofortes, H. G. Millier, London.
10,561. Indicating the Amount of Fluid in a Barrel, T. B. Burns, Bristol.
10,562. Mounting Window Sashes, R. A. Brackenbury, London.
10,563. Distributing Powders, A. A. Furst and F. Becker, London.
10,564. Frost-proof Pipe, T. B. Burns, Bristol.
10,565. Tires for Vehicles, H. Lindsay - Bucknall, London.
10,566. Canvas Grips and Appliances, H. Marles, Brighton.
10,567. Hospital Tables and Cases, R. F. Reynolds, Leeds.
10,568. Gas-producing Apparatus, V. I. Feeny.—(*P. Carmien, A. Yvonnet, and M. Billion, France.*)
10,569. Rapid Timber Dryer, J. Black and R. Black, Liverpool.
10,570. Bodkin, T. W. Johnson and C. Charman, Redditch.
10,571. Dust and Draught Excluders, E. Pollard, Bradford.
10,572. Carrier Pigeon Message Holder, F. W. A. Mylius, Manchester.
10,573. Bicycles, W. F. Woods, Liverpool.
10,574. Phosphate Ore Utilising Process, E. Cuylits, Brussels.
10,575. Motor, E. M. Foot, London.
10,576. Driving Chains, &c., of Cycles, P. A. Craven, London.
10,577. Making Chlorates of Sodium, A. Wolf and W. S. Blythe, Manchester.
10,578. Mowing and Reaping Machines, A. McGregor, Manchester.
10,579. Spring Ambulance Hammock, H. W. Williamson, London.
10,580. Quick Return Motion for Drilling Machines, C. H. and C. H. Clifton, and C. W. B. Crossley, Johnstone.
10,581. Tires, G. C. Nesbitt, London.
10,582. Track Brakes for Railway Cars, L. Kneedler, E. Vorpe, and J. S. Everitt, London.
10,583. Teeth of Rakes, W. Goldsworth, Stony Stratford.
10,584. Coffins, J. Ursell, Cologne.
10,585. Oilers or Portable Lubricators, J. C. Chandler, London.
10,586. Tiled Hearths or Flooring, J. Simpson, London.
10,587. Steam, Oil, and Gas Engines, R. J. Eke, London.
10,588. Manufacture of Cycles, &c., G. Shrewsbury, London.
10,589. Pneumatic Tires for Cycles, &c., H. Mead, London.
10,590. Making Pneumatic Tires, J. A. Calantarients, London.
10,591. Toothed Parts of Machinery, F. Ludewig, London.
10,592. Toothed Parts of Machinery, F. Ludewig, London.
10,593. Hat Pins, R. Bürgemeister, London.
10,594. Picture and Curtain Rods, J. J. Bate, Liverpool.
10,595. Cycle Saddles, J. J. Bate, Liverpool.
10,596. Railway Keys, A. G. Sidwell, Birmingham.
10,597. Cycles, E. Hale, Liverpool.
10,598. Mounting Carriage Bodies, D. L. Salomons, London.
10,599. Cycle Riding Appliances, W. C. Dyer and G. H. Rayner, London.
10,600. Stands or Receptacles for Olives, K. M. Barber, Birmingham.
10,601. Body Rollers for Horses, &c., J. J. Wilson, Birmingham.
10,602. Capstan or Turret Lathes, A. Herbert, London.
10,603. Thrashing Machines, M. Dornwald, London.
10,604. Construction of Cycle Wheels, J. Davidson, London.
10,605. Tire for Cycles and Vehicles, W. H. Simmonds, London.
10,606. Breech-loading Guns and their Mountings, D. Vickers, A. T. Dawson, and G. T. Buckham, London.
10,607. Purifiers for Middlings, &c., H. Simon, London.
10,608. Tumler Electric Switches, The Edison and Swan United Electric Light Company and C. F. Proctor, London.
10,609. Pipe Coating Material, F. Espir.—(*W. C. Jack, Tonkin.*)
10,610. Pneumatic Tires, G. W. C. and A. E. Noble, London.
10,611. Wheels and Tires, W. H. and J. R. Caldecourt, London.
10,612. Baths, J. Ott and B. W. Conti, London.
10,613. Covers for Pneumatic Tires, R. Kitchen, London.
10,614. Rim for Cycle, &c., Wheels, R. Kitchen, London.
10,615. Vapour Burners and Lamps, J. S. Wood, London.
10,616. Displaying Wall Papers, H. H. Lake.—(*J. J. Reid, United States.*)
10,617. Elastic Wheel Tires, A. G. Bessemer, jun., London.
10,618. Preventing Accumulation of Coal Dust in Mines, H. Bell, A. L. Steavenson and R. Harle, London.
10,619. Lamps for Cycles and Vehicles, P. H. Emanuel, London.
10,620. Roofing Plates or Sheets, A. J. P. Whitaker, London.
10,621. Papermakers' Beating Engines, W. H. Caldwell, London.
10,622. Engines, R. L. Weighton and D. B. Morison, London.
10,623. Manufacture of Woven Fabrics, H. Spiegler, London.

18th May, 1896.

10,624. Stoppers for Bottles, E. Hurry, Newcastle-on-Tyne.
10,625. Cooking Eggs, T. H. Simmonds, London.
13,626. Brakes for Cycles, J. E. Blackledge, Manchester.
10,627. Testing Butter and Margarine, R. Wells, Scarborough.
10,628. Audible Signals or Alarms, G. Rydill, Dewsbury.
10,629. Lavatory Basins, Baths, &c., F. C. Lynde, Manchester.
10,630. Cycles, J. Whitehead and J. A. Crane, Birmingham.
10,631. Tires, W. F. Gedye, London.
10,632. Liberating the Hands in Bicycle Riding, J. J. Jonas, London.
10,633. Mouthpieces of Tobacco Pipes, A. E. Gilbert, Newcastle-on-Tyne.
10,634. Tire, W. Meadows, London.
10,635. Balling Gun for Animals, J. A. Bosworth, jun., Leicester.
10,636. Automatic Saddle, J. McKenny and P. Redmond, Dublin.
10,637. Screw-neck Gully for Drains, J. W. Mearns, Sunderland.
10,638. Bicycle Brakes, I. Trolley, Grantham.
10,639. India-rubber and Vulcanite, A. Hobbs, Newport.
10,640. Horseshoe, K. Tucker, Chard.
10,641. Automatic Machine, A. W. Cutting and G. Roberts, London.
10,642. Driving Gear for Cycles, J. M. Davies, Dublin.
10,643. Coupling Attachment for Bicycles, W. P. Kelly, Dublin.
10,644. Cord Clutches or Grips, G. Leadbetter, Ledbury.
10,645. "Byron" Bicycle Brush, H. E. Dolphin, Liverpool.
10,646. Drums or Vessels for Petroleum, D. Caird and the Iron and Steel Plant Company, Limited, London.
10,647. Beams, H. Laing and W. Hök, Newcastle-on-Tyne.
10,648. Ladies' Shirts, M. E. Carrington, Manchester.
10,649. Cycles, J. A. Crane and J. Whitehead, Birmingham.
10,650. Buffer Tube Saddle Spring, J. Lane, Nottingham.
10,651. Rims for Cycles, A. Maltby, London.
10,652. Air Chambers for Pneumatic Tires, A. Maltby, London.
10,653. Pneumatic Tires, A. Maltby, London.
10,654. Non-slipping Bands for Tires, A. Maltby, London.
10,655. Stamping Blocks of Butter, J. C. Lawson, London.
10,656. Shaping Leather Loops, E. R. Royston.—(*E. Spear and F. L. Middleton, United States.*)
10,657. Machinery for Slitting Leather, E. R. Royston.—(*E. Spear and F. L. Middleton, United States.*)
10,658. Machinery for Cutting Pockets, E. R. Royston.—(*E. Spear and F. L. Middleton, United States.*)
10,659. Machinery for Making Loops, E. R. Royston.—(*E. Spear and F. L. Middleton, United States.*)
10,660. Means for Inflating Toy Balloons, J. Harris, Manchester.
10,661. Construction of Bottles, L. E. Keegan, Dublin.
10,662. Bicycle and other Tires, E. W. Hughes, London.
10,663. Sand Box for Use on Golf Courses, C. Playfair, Glasgow.
10,664. Means of Raising Water, &c., C. J. Eyre, Brighton.
10,665. Tires, J. Murray and C. R. Alexander, London.
10,666. Manufacture of Cycle Frames, C. Binks, York.
10,667. Driving Gear for Cycles, A. E. Hodder and F. Sheridan, London.
10,668. Protector against Rain, J. Gilbert and H. O. Box, London.
10,669. Electrical Variable Speed Gear, A. G. New, Surrey.
10,670. Electrical Variable Speed Gear, A. G. New, Surrey.
10,671. Lamps, A. E. Purrott and E. W. Willard, London.
10,672. Tubular Tire for Wheels, E. A. Tavernier, London.
10,673. Regulating Gas, C. A. Finch and H. J. Ingle, London.
10,674. "Careful" Cuff, G. Care and T. Tabrar, London.
10,675. Lamps for Burning off Paint, C. Phillips, London.
10,676. Lasts, B. Toone and J. W. Black, London.
10,677. Combined Dress Skirt Band, A. Bradbury, London.
10,678. Devices for Curling Hair, A. E. Roberts, London.
10,679. Easy Chair, H. Burgess, London.
10,680. Attachment to Travelling Caps, C. W. Shepherd, London.
10,681. Soaps, J. Ascough, London.
10,682. Storing and Delivering Address Cards, &c., H. Schenk, London.
10,683. Shearing Textile Fabrics, A. Sykes and W. E. Yates, Ltd., London.
10,684. Ball Bearings, E. Rother, London.
10,685. Velocipedes, C. Chambers, London.
10,686. Combined Set Square and Ruler, J. Lohmeyer, London.
10,687. Utilising the Tidal Flow, J. Lohymeyer, London.
10,688. Frames of Bicycles, O. Imray.—(*E. Béranger and A. Chobert, Belgium.*)
10,689. Aromatic Aldehydes, O. Imray.—(*The Farbwerke vormals Meister, Lucius, and Brüning, Germany.*)
10,690. Mechanism for Stopping Machinery, Tangyes Limited, and J. Robson, jun., London.
10,691. Wheels for Cycles, J. G. Ferguson, London.
10,692. Holdfast Excentric Grip, J. Gardner and J. Such, Cheltenham.
10,693. Hooks and Chains Combined, H. S. Woodd and T. Crisp, London.
10,694. Sprocket Chains, F. Myers, London.
10,695. Tire for Wheels of Cycles, A. R. Richards, London.
10,696. Lubrication of Bearings, H. H. Lake.—(*Todtenhaupt and Helms, Germany.*)
10,697. Wheels for Velocipedes, &c., W. J. Ingram, London.
10,698. Electric Alarm Apparatus, H. C. Bird, London.
10,699. Pneumatic Tires, J. Slee, Liverpool.
10,700. Elastic Tires for Cycles, &c., E. Gerard and A. Picon, London.
10,701. Pedals of Cycles for Racing Purposes, O. Taylor, London.
10,702. Ventilating Fur Garments, H. W. Lane and W. H. and H. M. Smith, London.
10,703. Gunpowder, J. House and A. Gillingham, London.
10,704. Bicycles, W. Atkinson, London.
10,705. Tires of Cycles, A. A. Furst, London.
10,706. Adjustable Support for Bicycles, G. Woolley, London.
10,707. Cycle Saddles, L. Houghton, London.
10,708. Railway Signal Indicating Appliances, A. H. S. Daniell, London.
10,709. Rotary Pumps and Engines, L. S. d'Iszoro, London.
10,710. Incandescence Spirit Lamps, E. Berker, London.
10,711. Mechanism for Marine Propulsion, L. Lawrence, London.
10,712. Mechanical Organs, &c., A. A. M. Gavioli, London.
10,713. Machines for Vanning Ores, T. H. Tregoning, London.
10,714. Pneumatic Tires, I. Nasch, London.
10,715. Manufacture of Manures, F. W. Saatmann, London.
10,716. Fishing, F. W. Saatmann, London.
10,717. Tubes, A. Racic, London.
10,718. Positive Lead Electrodes, H. O. Tudor, London.
10,719. Weighing Machines, C. Ingrey, London.
10,720. Braking Vehicles, I. A. Timmis, London.
10,721. Lighting Cigars, L. Huttenbach, London.
10,722. Pneumatic Tires, W. Maddock, London.
10,723. Apparatus for Unchaining Cattle, J. Vietheer, London.
10,724. Tires of Wheels for Bicycles, C. M. Glen, London.
10,725. Generating Gas, G. Webb, jun., and J. W. Kelly, London.
10,726. Toasting Forks, F. Hutchins, London.

19th *May*, 1896.

10,727. Lever Crank for Bicycles, R. Wilcox, London.
10,728. Generating Acetylene, J. Swinburne, London.
10,729. Cycles, K. Gengnagel, St. Leonards-on-Sea.
10,730. Tires of Wheels for Carriages, J. Hayes, Lincoln.
10,731. Velocipedes, C. C. Hopkins, Birmingham.
10,732. Securing Cycle Pumps, W. H. Henser, Birmingham.
10,733. Cycle Parcel Carrier, W. H. Henser, Birmingham.
10,734. Holders for Pipe Cleaners, G. H. Hill, Birmingham.
10,735. Raking Hay into "Hacks," S. H. Ody, Bristol.
10,736. Winding Fabrics upon Rollers, L. Schreiner, Manchester.
10,737. Disinfector for Water-closets, W. Preston, Leeds.
10,738. Tires for Bicycles and other Vehicles, G. S. Ram, Coventry.
10,739. The Presto Bottle Lock, J. Dudley, Southsea.
10,740. Egg-cutter Guides, H. B. Everest, London.
10,741. Manufacture of Boot Heels, B. Seimert, London.
10,742. Fastening Inflated Tires, C. Merington, Penge.
10,743. Brass Cornice Pole Ring, F. P. Cochrane, Leith.
10,744. Combining Solid and Cushion Tires with Pneumatic, J. A. Bonds, L. Dawes, and S. Dawes, London.
10,745. Pneumatic Tires, D. Young.—(*The Self-healing Pneumatic Tire Company, United States.*)
10,746. Pneumatic or Solid Wheel Tires, J. H. Evans, London.
10,747. Hydraulic Pumps, A. G. Browning, Manchester.
10,748. Nails and Spikes, H. E. Fuller, Birmingham.
10,749. Stowing Heavy Plates in Ships, T. Banks, Glasgow.
10,750. Cycle Pneumatic Tires, R. J. Hamilton, Glasgow.
10,751. Voting Machines, A. O. Abbott, Glasgow.
10,752. Degreasing Leather, G. E. Wright and W. Monk, Manchester.
10,753. Scouring Textile Fabrics, J. D. Asquith, Bradford.
10,754. Folding Arm to Cranks of Cycles, W. H. Havers, Norwick
10,755. Wheels of Pit Corves, S. Shepherd, jun., and E. Shepherd, Sheffield.
10,756. Self-opening Umbrella Frames, C. W. Bremshey, Glasgow.
10,757. Cycle Felloes, R. Turnbull, sen., and R. Turnbull, jun., Newcastle-on-Tyne.
10,758. Measuring Taps, J. H. Airey, Sunderland.
10,759. Chain Protector for Cycles, F. Lott, Liverpool.
10,760. Detachable Mud Guards for Cycles, F. Lott, Liverpool.
10,761. Stoppers for Glass Bottles, J. H. Trinder, London.
10,762. Ornamental Sheet Belts, C. F. Gaunt, Birmingham.
10,763. Siemens' Regenerative Furnaces, F. Svoboda, Glasgow.
10,764. Ladies' Cycling Skirt, F. H. and L. H. Stirling, Edinburgh.
10,765. Automatic Gear for Brakes, J. S. Hainsworth, London.
10,766. Coal-dust Mixing Apparatus, &c., F. Forst, London.
10,767. Bicycle Stand, F. Forst, London.
10,768. Folding and Collapsible Boxes, J. Thompson, London.
10,769. Valves for Pneumatic Tires, J. Shipway, London.
10,770. Wheels for Cycles and Carriages, F. Jones, Long Ditton.
10,771. Automatic Matchbox, A. Minter, London.
10,772. Elevators, Otis Elevator Co., Ld.—(*Otis Bros. and Co., United States.*)
10,773. Tires, T. and C. Colls, Barnt Green.
10,774. Water-tube Boiler, J. P. Hall, London.
10,775. Wheels, S. H. James, London.
10,776. Tires and Rims for Cycles, &c., T. Fenwick, London.
10,777. Bridge Rim and India-rubber Tire, F. Ochs, Reigate.
10,778. Exhibiting Photographic Pictures, A. N. Petit, London.
10,779. Tire, A. Hone, London.
10,780. Wheel, J. J. Ney, London.
10,781. Applying Electricity to Vehicles, H. J. Dowsing, London.
10,782. Ruler and Blotter, R. B. Whiteside and W. Tuck, London.
10,783. Engines for Pumping-up Beer, A. E. Hart, London.
10,784. Washing Granular Substances, R. Moodie, London.
10,785. Pneumatic Tires, J. Dunkley and E. Harber, London.
10,786. Sash Fasteners, A. E. Bray, London.
10,787. Tire Protectors, A. E. Cooper, London.

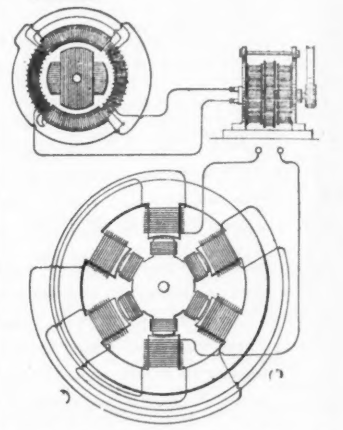
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

555,190. Alternating Motor, *N. Tesla, New York.—Filed May 15th*, 1888.

Claim.—(1) In an electro-magnetic motor, the combination of independent energising circuits, one adapted to be connected with a source of alternating current, the other arranged in inductive relation to the said first circuit whereby the motor will be operated by the resultant action of the two circuits, as set forth. (2) The combination in an electro-magnetic motor, with an alternating coil or conductor and a closed circuit conductor in inductive relation thereto, of an armature mounted so as to be within the field produced by the coil and closed conductor, as set forth. (3) The combination in an electro-magnetic motor, with energising coils adapted to be connected with the generator of induced coils and independent energising coils in circuit therewith and arranged to produce a shifting movement of the points of maximum magnetic effect of the motor, as set forth. (4) The combination in an electro-magnetic motor of a series of independent energising coils or sets of coils and induced coils wound on all the energising coils or sets of coils but the last of the series, the first energising coil or set of coils being included in circuit with a generator and each succeeding energising coil or set of coils being in circuit with the induced coils of the next preceding energising coils of the series. (5) In a system for the electrical transmission of power the combination of an alternating current generator, a motor with an energising coil or coils connected with the generator, secondary coils in inductive relation to said energising coils, and energising coils in circuit therewith arranged in substantially the manner set forth to produce a movement or rotation of the points of maximum magnetic effect of the motor, as set forth. (6) In an electro-magnetic motor the combination of independent energising circuits, one for connection with a source of alternating currents, the other in inductive relation to the first, whereby a rotary movement or projection of the field poles will be produced by the conjoint action of the two and an armature mounted within the influence of the field produced by the energising circuits and containing closed coils or circuits, as set forth.

555.190



555,296. Crosshead, *G. A. Anderson, Waynesborough, Pa.—Filed August, 13th*, 1895.

Claim.—(1) The combination, with a crosshead, a hollow pin journalled therein and provided with tapering end portions and a lateral hole for the piston-rod to pass through, and a connecting-rod provided with a forked end engaging with the tapering end portions of the pin; of a plate bearing against the connecting-rod over the smaller end of the pin, a nut let into the said pin in front of its said lateral hole, and a pin passing through a hole in the said plate and screwed into the said nut, substantially as set forth. (2) The combination, with a crosshead, a pin journalled therein and provided with a lateral hole for the piston-rod to pass through, and a connecting-rod provided with a forked end engaging with the end portions of the said pin; of interlocking guide-lugs on the end of the pin and on the eye of the connecting-rod adjacent thereto, whereby the alignment of the said hole with the piston-rod is assured, substantially as set forth. (3) The combination, with the main portion of a crosshead, a cap, and a crosshead pin journalled in the said main portion and cap; of thin liners, and covers of soft material enclosing the said liners and interposed between the said cap and main portion, and means for drawing together the said cap and main portion, substantially as set forth.

WAGES IN THE ENGINEERING TRADE.

By J. STAFFORD RANSOME.

III.—THE CAUSES OF THE VARIATION IN THE RATES.

WITH a view of showing as nearly as possible the actual difference between the rates of wages in the various branches of the trade, I give below a list of them, together with the localities where the maximum and minimum rates obtain.

In explanation of this table, which is somewhat full and as up to date as can be, I would say that it is possible that, in a few instances, there may be districts in which wages exceeding those recorded as the maximum and minimum are paid. But if such is the case, I have been unable to obtain data with respect to them. With this reserve, it is merely necessary to point out that, as far as my particulars go, the variations given in the table represent the extremes between the maximum and minimum rates. In other words, the figures in the fourth column indicate the amount per cent. which would have to be deducted from the maximum rates, to bring them down to the level of the minimum.

It is as well to mention that in some of the towns a variety of rates are paid to men who are classed under the same trade. Consequently it does not follow that some of the towns in the minimum column do not pay a portion of their men at higher rates, nor that some of the towns in the maximum column do not pay a portion of their men below the maximum rate. The most extreme instances of this are afforded in the case of the West Hartlepool and Tees districts, where the wages of "felters" are both lower and higher than anywhere else in the country; and, with regard to the wages of millwrights, Birmingham will be found to figure in both the minimum and maximum columns.

I quote no figures of the actual wages paid in any case, as much of the information given me on the subject is of a more or less confidential nature. The percentage method, however, affords a clear means of showing at a glance the comparison of the standards. Then, again, the actual wages are continually changing, whereas the portions between the rates do not vary nearly so much.

Table showing the Extremes of Rates of Wages in various Districts, and the Amount of Variation between Maximum and Minimum Rates in each Section of the Trade.

Sections of the trade.	Localities where the minimum wage is paid.	Localities where the maximun wage is paid.	*Amounts of variation in rates. p.c.
Angle iron smiths	Glasgow	London	30
Angle iron strikers	Glasgow	London	79
Boat builders	Dartmouth	Newcastle-on-Tyne	80
Boiler men	Belfast	Newcastle-on-Tyne	46
Brassfinishers	Lincolnshire	London	42
Brass moulders	Birmingham, Leeds	London, Bolton	31
Cabinet makers	Sunderland	Newcastle-on-Tyne	4
Caulkers	Glasgow	Tees, Hartlepool	18
Chippers	Lincolnshire	Tees, Hartlepool	51
Coppersmiths	Belfast	Cardiff	31
Crane men	Dundee	Tees, Hartlepool	42
Engine men	Bedford, Bolton	Bolton	57
Dressers	Belfast	Tees, Hartlepool	67
Erectors	Dundee	London	34
Felters	Tees, Hartlepool	Tees, Hartlepool	37
Fettlers	Belfast	Tees, Hartlepool	69
Firemen	Stroud	Lincolnshire	50
Fitters	Barnsley, Dundee	London	37
Fitters' labourers	Dundee	London	37
Flangers	Southampton	Birmingham	6
Foundry labourers	Stroud	Cardiff	48
Furnacemen	Liverpool, Birkenhead	Barrow-in-Furness	32
General labourers	Glasgow	London	66
Grinders	Lincolnshire, Belfast, Manchester	Sunderland	52
Hammermen	Belfast, Newcastle-on-Tyne	London	23
Hand drillers	Belfast	London	48
Holders-up	Glasgow	London	30
Iron moulders	Barnsley	London, Sheffield, Manchester, Liverpool, Bolton	36
Joiners	Dartmouth	London	40
Platers	Leicester	London	33
Platers' helpers	Bradford	Sunderland	53
Machine borers	Belfast	London	61
Machine drillers	Belfast	East of Scotland	51
Machine screwers	Belfast	London, Barrow-in-Furness	51
Millwrights	Birmingham	London, Birmingham	35
Outworks men	Dundee	London	35
Packers	Glasgow	Liverpool, Birkenhead	10
Painters	Belfast	Barrow-in-Furness	65
Patternmakers	Keighley	London	30
Planers	Lincolnshire	London	52
Plumbers	Lincolnshire	Barrow-in-Furness	40
Polishers	Belfast	Newcastle-on-Tyne	10
Punchers	Leeds	Lincolnshire	37
Red-leaders	Belfast	London	38
Riggers	Tees, Hartlepool	Liverpool, Birkenhead	22
Riveters	Bradford, Leicester	London	27
Rivet boys	Southampton	East of Scotland	52
Sail-makers	Newcastle-on-Tyne	London	16
Sawmill men	Belfast	Hull	46
Sawyers	Barrow-in-Furness	Barrow-in-Furness	47
Shapers	Dundee	London	47
Shipwrights	Hull	London	20
Slingers	Manchester	Newcastle-on-Tyne	29
Slotters	Lincolnshire	London	52
Smiths	Bedford, Huddersfield, Leicester, Lincolnshire, Stroud	London, Sheffield	40
Smiths' finishers	Belfast, Tees, Hartlepool	Belfast	18
Smiths' strikers	Portland	London, Cardiff	40
Spar-makers	Tees, Hartlepool	Liverpool, Birkenhead	16
Strappers	Glasgow	Liverpool, Birkenhead	10
Turners	Barnsley	London	47

* The percentages given in this column represent the extent to which the minimum rate is lower than the maximum.

On reference to the above table, it will be seen that the amounts of variation differ greatly in the various sections of the trade; the smallest difference being 4 per cent., and the highest 79 per cent. In the more important trades such as erectors, fitters, iron moulders, millwrights, patternmakers, platers, and riveters, the extremes are not so great, the minimum, speaking roughly, amounting to about two-thirds of the maximum. The above sections, with the smiths and machine hands, such as turners, slotters, planers, and so on, may be said to form the chief trades followed in ordinary engineering works; but the variation in the rates of pay of smiths and machine men is naturally greater than in the trades first named, as the degrees of skill brought to bear in them is very much more marked. A "smith" may mean anything, from a man doing rough routine work of a very simple nature to an extremely high-skilled man, who is working intelligently to elaborate and complicated drawings. Then, again, some "machine men" draw as much as 50s. a-week, while boys and labourers are largely employed on the commoner class of work, and come under the heading of "machine men." In some of the cases where the table shows a very great discrepancy of rates, this is to be partially attributed to the very different class of engineering work carried on in different districts. For undoubtedly a certain class of work will often attach itself to an individual district. It does not, however, in the least follow that the quality of work turned out by two firms in opposing districts, where the wages standards are quite different, should not be equally good.

In looking into the causes of the great difference in wages, one really ought to put London on one side and deal with it separately. It is so immensely larger than any other district, its population being nearly ten times as great as that of any of the provincial centres; and, as the metropolis of the world, the conditions of the work carried on there, and the surroundings of the workers, are entirely different from those of any provincial town. To deal with London first, the great difference between London and provincial wages is to be attributed to a variety of causes. Of these, perhaps the most obvious lies in the fact that the metropolis is the wrong place in which to attempt to make ordinary machinery. Engineers have found out that it does not pay to manufacture a cheap or inferior class of machine in London, owing to the very high cost of raw materials, and the excessive expenditure entailed in handling goods and putting them on board ship. Then, again, high rentals and limited space tend to handicap the London manufacturer in turning out common machinery. There are, however, many very successful and important manufacturing engineering firms in London, but they may be divided into two classes: (1) Those who never attempt to do anything but a very high quality of work, and (2) those who confine themselves to manufacturing special or patented articles which cannot be made elsewhere. Such firms require only first-rate men, and can afford to pay them high wages. But in no case would it answer the purpose of men to take work in London at provincial prices; for apart from the fact that their living expenses are heavier in the metropolis, the hours of work are, as a rule, longer—fifty-four hours a week as against fifty-one, and sometimes forty-eight—and shop discipline as to timekeeping and so on is generally more strictly adhered to.

There is another class of London firm who occupy men in the engineering trade. I refer to the very large number of very small firms whose work is more accurately described as millwrighting than anything else, and whose business is essentially local. The *raison d'étre* of such firms is, of course, brought about by the enormous capacity of the London district and the vast sums of money annually expended there to keep its factories, ships, docks, &c. in repair. Much of this money is of necessity expended locally, and a very great deal of it finds its way into the little repairing shops. Such firms have, of course, to pay the local rate of wages, although the work turned out by them is often quite inferior; for, owing to the large number of petty employers, and the hand-to-mouth manner in which many of them carry on their trade, they are unable effectually to combine for the purpose of reducing wages.

Another great cause of the high wages of London is to be found in political influence. For many years past the labour question has been one of the accepted matters for politicians on both sides of the House to juggle with; for to accord something or other, good or bad, to the working man has often served to bring into notoriety public men of various shades of opinion. The Government factories have naturally formed the happy hunting-ground of these gentlemen, and as London and the district abound in this class of institution, the metropolitan wages have been subjected to a far greater political pressure than those of any other centre. In the engineering and shipbuilding trades, the influence of Woolwich, Enfield, Sheerness, and even Chatham are felt, and the influence is one which hampers metropolitan engineers by unduly lifting wages. In a Government shop the wages are always high, but they are surrounded by so many other advantages to the men, that private firms, who do not offer these advantages to their men, are forced to pay still higher rates. The advantages to the men, apart from the question of wages, in Government workshops where piece work is not the rule are:—

(1) That they need not work at all hard, as Government departments not being worked commercially, the cost of articles produced there is practically immaterial.

(2) Shop discipline is at a low ebb, as owing to the continual interference of politicians who are temporarily in power, the hands of the permanent managing staff are tied, and they are consequently unable to exercise a business-like control over the working arrangements.

(3) There is a greater chance for inefficient men to retain permanent employment, than is the case in private works.

(4) A considerable number of the permanent hands become, in the course of time, what is known as "privileged," and, among other things, become entitled to a pension.

There can be no sort of doubt that the existence of factories carried on under these conditions must materially influence the rates of wages paid by private firms in the neighbourhood, and, bearing in mind the influences which are constantly at work for keeping up the price of labour and keeping down the efficiency of the men employed in Government shops, one cannot be altogether surprised at the line adopted by certain London employers, who recently complained bitterly of so little Government shipbuilding being given out to firms in the metropolis. No doubt, if Government is largely instrumental in unduly keeping up the wages of the metropolis, it may be contended that it should be under some sort of a moral obligation with regard to the private firms who suffer from its action, to give them work at a higher price than would be paid to other firms more fortunately situated. But I am unaware that any Government in any country is in the habit of recognising moral obligations of any sort, and my personal opinion is that any endeavour to enforce a moral claim of this sort would prove a very arduous and profitless undertaking.

Reverting to the question of engineering wages generally throughout the country, the four chief influences which directly determine and control the rates are undoubtedly:—

(1) The degree of local competition for work between the men.

(2) The degree of local importance of the industry; or, in other words, the proportion of the men in the trade to the total local population.

(3) The size of the local firms employing the men.

(4) The local cost of raw materials.

There are two other influences which occasionally, and in a strictly limited manner, may be considered to have some direct effect on wages. These are:—

(5) The cost of living.

(6) The quality of the work turned out.

To deal with the last two points first, I am bound to say that, with the exception of London, I cannot find any important centre where the rates of wages seem to be proportionate to the cost of living, as compared with other towns. The only other marked instances of this rule holding good are to be found in little out-of-the-way places, where there is no doubt that wages and living are often both extremely low. In the long run the increased cost of living, or, in other words, the advance of civilisation, is undoubtedly the main cause of the steady rise in wages; but, speaking locally, I do not find that one can with any accuracy say, in comparing the big provincial centres, that the engineering wages are proportionate to the cost of living.

With regard to wages corresponding to quality of work, this is extremely limited in the engineering trade. As explained in a previous article, by far the greater part of the trade union energies in this industry have for years been devoted to endeavouring to level up the wages of the inferior men, and leaving the better class of men to shift for themselves; and it is only natural that the great pressure brought by the trade unions, while failing to raise wages all round, should show some results in the way of distorting the pay sheet in favour of the inefficient workman. Consequently we see, over and over again, factories working side by side where the wages are the same, but the quality of the work entirely different.

It is only when we find whole districts devoted to one particular class of engineering work, and are able to compare them with other whole districts which are devoted to another class—higher or lower—of engineering work, that we can see that occasionally the wages in the districts where the rough work is done are lower than those of the other districts. But even this rule is not a very safe one, all along the line.

The first four influences mentioned in the above list afford really the important, or at all events the palpable reasons for the variations; and as they are all more or less dependent on each other and run together, they may be considered simultaneously. Most people are agreed that where there is an abundance of labour, there will be a tendency for wages to be cheap. That is so obviously a truism, that no argument is necessary to enforce the statement.

The supply of labour in a given industry is greatest in localities where such industry is large in proportion to the size of the district. The reason for this is, that a considerable proportion of the inhabitants are born and bred to that industry, and from father to son learn the trade as a matter of course. In fact, the inhabitants of those centres live in an atmosphere of that industry, and it is an effort rather than otherwise to emancipate themselves from it and learn another trade. In short, it is the natural industry of the place. The neighbourhood itself has a great hold on the men and their families. They are born there, and their social surroundings are there, and only such of them as cannot get on, or are tempted by higher wages elsewhere, trouble to leave the place.

It will be found that in measure as an industry becomes important locally, so the firms, who find employment for the men in it, become large and powerful. Such firms are in a far better position to afford continual work to a large number of hands; and in many other ways large firms are preferable to small ones from the point of view of those employed. Where firms are large, it will, in nine cases out of ten, be found that raw materials are cheap in the district, for it is only in such places that firms develope into colossal proportions, unless they are kept going by artificial or extraneous influences. For it naturally does not pay under ordinary circumstances to employ thousands of men in making machinery in districts where every pound of coal and iron costs more than it does elsewhere.

Thus in London there are very few large firms, but an enormous number of medium and small ones. Raw materials are high, the proportion which the engineering industry bears to the total population is insignificant, the labour supply spasmodic, living is more expensive than elsewhere, and as a rule nothing but high-class work is turned out in the metropolis; consequently wages arehigh—the highest in the country. The next four centres where wages are highest—Sheffield, Manchester, Birmingham, and Liverpool—are all better off as regards raw material, but the engineering firms, with the exception of some in the Manchester district, are mostly comparatively small. The labour supply is small in proportion to the population, Sheffield and Birmingham having as their staple industries their cutlery and hardware trades, and as engineering centres they are not very important. Liverpool is more a shipping port than an engineering centre, and Manchester, though a big engineering centre, has cotton and dry goods as its overwhelming industry. Perhaps the quality of the Manchester work has something to do with its high wages; but, in any case, the labour question there has had to submit to be handled from time to time by local politicians and faddists.

Newcastle, Sunderland, and Glasgow, are examples of centres where an excellent quality of work is turned out, but where wages are low. They are natural engineering and shipbuilding centres, and very large ones. Raw materials are cheap, and plenty of labour is forthcoming.

Belfast, where a precisely similar work is carried on, and where living is certainly no more expensive, pays higher wages, for the reason that the proportion of the engineering element to the total population is not so great. Belfast wages are, however, cheaper than those of Bolton, Liverpool, Birmingham, Manchester, Sheffield, and London, because the trade in that town is mainly in the hands of a few large firms.

To sum the whole matter up, it would appear that wages are low in such districts as by their position and surroundings may be termed the natural homes of the industry, and high where that industry is carried on under artificial or forced circumstances. One can readily understand, however, that for one reason or another a great deal of manufacturing engineering must be carried on in the "unnatural" districts, but when such is the case the employers have to depend either on the nature or the quality of their work to bring them in better prices and recoup them for their heavier outlay.

Going a little further back into the general question, I would say that nature and the railway companies have a great deal more to do, primarily speaking, with fixing the localities and wages in the engineering industry than have either master, man, trade union, or politician. For nature points out the localities where the work can be carried on cheapest, and the railway companies determine how far other districts may be artificially brought in to serve the same purpose, and the rates of local wages are as a matter of course dependent on these considerations.

RAILWAYS IN ASIATIC TURKEY.

A far-reaching interest attaches to the report furnished to the Foreign-office by Major E. Fitzgerald Law, and published as a parliamentary paper, treating of the railways in Asiatic Turkey. In compliance with the instructions received by him from Sir Philip Currie, the British Ambassador at Constantinople, Major Law, prior to the preparation of his report, went over all the railways which have been established in that part of the Sultan's dominions, with the exception of the short line between Jaffa and Jerusalem. It is a singular fact, and one which Major Law says is not very easily to be accounted for, that whereas at the outset railway enterprise in Asia Minor was entirely in English hands, only one line—the Smyrna-Aidin Railway—continues so at the present time. The circumstance is obviously important as regards the general interests of British trade. Not only has the supply of large quantities of railway material been obtained from other countries than Great Britain, but the diminution in the number of Englishmen employed also operates adversely.

Respecting the future, Major Law does not expect any important extension of the railway system in Asiatic Turkey at an early date, beyond the completion of railways already commenced. But although there is no immediate prospect of the construction of the Euphrates Valley Railroad, Major Law admits "the practical certainty that such a road will sooner or later be built." He speaks of the Euphrates Valley and the Persian Gulf as "the inevitable mail route to India." This, however, waits on the construction of direct rail communication between Bussorah and Western Europe *viâ* Constantinople. Until such direct communication is established, Major Law is of opinion that the idea of a route to India through Turkey, even for mails, is little better than a dream. With regard to the general use of such a line, Major Law is doubtful if forty-eight hours could be saved, as compared with the Suez Canal, in taking this route to Bombay. If this be all, he "cannot believe" that such a comparatively small saving of time would be found an adequate compensation for the trouble and expense involved in two transhipments, one at Haifa on the Mediterranean coast, and the other at Bussorah.

The Haifa-Damascus-Hauran Railway, with its authorised branches, is described as one of the most important of existing or proposed railways in Asiatic Turkey. At present it belongs mainly to the projected class. It has been thought that this line was destined to become the terminal of the "much talked-of" Euphrates Valley Railway, which, by connecting the Mediterranean with the Persian Gulf, would, it is assumed, become the great highway to our Indian Empire. On this point Major Law says, "Whatever may be the importance of a railway from Haifa to Damascus, it seems to me improbable that this line will ever form part of an important route to India." When all existing conditions are fully considered, it seems clear, according to Major Law's judgment, that the Suez Canal must remain the proper route from Central and Western Europe to India for goods, troops, "and all passengers who are not careless of money, and who are not under pressing necessity to try and save one or two days on their journey." Among the varied proposals for railway construction which are still *in nubibus*, two are specified as worthy of consideration, and one of these has its bearing on the question of a route to India. This is the proposal to make a railway between Bagdad and Khannikin, on the Persian frontier. The special value of such a line, we are told, lies in the fact that ultimately it would almost certainly become an important section of a great trunk line connecting Teheran, Bagdad, and the Bosphorus, "perhaps reaching India by a branch from Kermanshah, through Ispahan and Yezd, eastward." The present road from Bagdad through Khannikin into Persia is described as the only one which presents no serious physical difficulties for communication between the Persian Gulf and the great central plateau of Persia—the most populous and fertile portion of the country. All heavy merchandise from India, for Ispahan or Teheran, now takes the route of the Persian Gulf to Bussorah, thence by the Tigris to Bagdad, and by Khannikin into Persia. Physical conditions appear to point out that "the great caravan road of the past" will become "the great railway highway of the future." With such prospects, there appears fair reason to suppose that a Bagdad-Khannikin railway would at once pay its way, and would stand in no need of a Government guarantee.

Financial difficulties have delayed the construction of the railway from Haifa to Damascus, so that up to the end of last September only five miles of permanent way had been completed, and there was no sign of any early renewal of the work. A recent letter in the *Times* is still further discouraging. The situation is rendered the more critical by the circumstance that the term of the original concession is expiring, and its renewal to the same parties is certain to be strenuously opposed by those interested in the rival railway already working from Beyrout *viâ* Damascus, to Mezerib in the Hauran, and proposed to be extended towards Djebel-el-Druz. The Beyrout Railway is throughout a narrow gauge line, a metre wide, and the several gradients encountered in crossing the Lebanon and Anti-Lebanon ranges have rendered it necessary to adopt the Abt system, with a third or rack rail, for the greater portion of the distance between Beyrout and Damascus. On the Lebanon range the railway attains an altitude of 4895ft., with an abrupt fall into the valley between the two ranges. With regard to proposals for extending the Beyrout-Damascus line northward, Major Law says it would seem impossible for a tortuous and narrow gauge railway passing over great altitudes to serve as a satisfactory terminal to an important trunk line. The Beyrout Railway is said to labour under the disadvantage of a defective harbour, whereas Haifa is described as being "by far the best natural port for large ships on the Syrian coast," and as capable of being improved at comparatively small cost. If such improvement is effected judiciously, it is thought that Haifa will become the most important commercial port south of Smyrna. The Damascus-Mezerib line commenced working in July, 1894, and the Beyrout-Damascus section has been opened quite recently.

The Jaffa-Jerusalem line, fifty-two miles in length, opened towards the close of 1892, has not yet proved very profitable in its working. A prolongation to the sea may improve its goods traffic, and an important increase of production for export may be expected to result from the establishment of the Jewish colonies in Palestine. The concession includes the right to make branches to Nablouz and Gaza. The railways so far described, and having their termini on the sea coast at Beyrout, Haifa, and Jaffa, are the only lines in Syria which have been to some extent constructed, or on which any serious work has been done. But a concession has been given for another line, from Damascus to Biredjik, on the Euphrates, proceeding by Homs, Hama, and Aleppo. This line would be about 280 miles long, and the concession has been taken over by the same company which owns the Beyrout-Damascus-Hauran Railway. Major Law remarks that at one time the project assumed great importance, on the supposition that the Anatolian Railway would be rapidly pushed forward to the head of the Euphrates, and that, by a junction on that river, Damascus and Aleppo would be placed in communication with a grand trunk line from Constantinople to Bagdad. But Major Law says, from all he can learn, it seems unlikely that the Damascus-Biredjik Railway will be proceeded with immediately. The concessionaires have been endeavouring to get the track of their line altered, so as to turn off at Homs and proceed to Baalbek, to join the Beyrout-Damascus line in the Lebanon Valley. This would deprive Damascus of a direct line to Aleppo. A project for a narrow-gauge railway along the Syrian Coast from Tripoli southward is one of the two proposals already referred to as worthy of consideration.

There are five railways working in Anatolia. These are the Anatolian line, the Smyrna-Aidin, the Smyrna-Cassaba, the Mersina-Adana, and the Moudania-Broussa. The first of these is the most important railway in Asiatic Turkey, the conceded mileage being, approximately, 875 miles. The lines from Haidar Pasha, near Scutari, to Angora, and from Eskishehr to Akshehr, a total of 528 miles, were open at the close of last year, and the final section of the Koniah branch, about 105 miles in length, will be working by the end of the present year. The remaining 242 miles which have been conceded represent the prolongation from Angora to Cæsarea, but it is unlikely that this portion of the undertaking will be open for some years to come. The construction of a railway meets with a somewhat peculiar difficulty in Turkey, owing to the circumstance that the Government allows no explosives to be used for blasting purposes, except the gunpowder which it furnishes itself, and which is apt to be none of the best. The Anatolian line is single throughout, but of the ordinary gauge, called by Major Law "broad," in distinction from "narrow." The rails and sleepers are of steel, and have been supplied exclusively from Germany, by the Essen and other large establishments. The orders for metal work for bridges were distributed in France, Belgium, and Germany. The last-named country furnished all the rolling stock.

In contrast with the Anatolian railway, the Smyrna-Aidin is a purely English undertaking. Major Law accordingly says it is satisfactory to note that so far this is "the only railway in Asiatic Turkey which, on its own merits and without Government assistance, has proved a profitable concern." The original length of the line to Aidin only was about 81 miles, but frequent extensions, including branches, have brought up the total to 318½ miles. A further prolongation of the line, so as to bring it to Tchai, where a junction could be effected with the Anatolian railway, is pronounced necessary, and must some day be made. The course of the Aidin Railway to Diner, with its projected extension to Tchai, marks the route by which the famous ancient cities of Asia Minor conducted their important commerce with the interior of Anatolia, "and pushed their trade eastward to the Euphrates and the Persian frontier." But the concession for extending the Aidin line to Tchai is held back, under influences doubtless operating at Constantinople. The Smyrna-Cassaba line, running parallel with the Smyrna-Aidin, at an average distance of about 40 miles, finds favour with the Turkish Government, and is expected to compete with the Aidin line. If the only flourishing railway in Asiatic Turkey can be damaged, we may presume there will be rejoicing somewhere. The present length of the Cassaba system is 165½ miles, but an extension to Karahissar will add 154 miles. The other two railways situated in Anatolia are of minor importance. The Mersina-Adana is only 41¾ miles in length, but would undergo great development if extended to Marash and Biredjik, supposing Biredjik to be connected with Damascus. The Moudania-Broussa Railway is still shorter, being only 26½ miles in length. It connects the ancient Ottoman capital Broussa with Moudania on the Gulf of Isnik, in the Sea of Marmora.

The history of railways in Asiatic Turkey is not satisfactory, either for England or for Turkey herself. Of four railways in Asia Minor built with English capital and English material, under English management, only one remains as an English undertaking, neither has there been any English participation in the great enterprises of the Anatolian Railway, or the reconstruction and extension of the Smyrna-Cassaba. The Aidin scheme was clearly founded on a commercial basis, and has prospered. Other projects have been bolstered up by Government guarantees, and the lines have followed the routes which the Government desired, the question of traffic development being thus treated as a secondary consideration. The new railways in Turkey have been financed by French and German banks, more speculative than those of England, and as a result British influence has been overborne. To the Turkish Government the guarantee system is working in a manner little less than disastrous. The conditions are so singular as to give the railway companies—to use Major Law's expressive phrase—"a direct interest in discouraging traffic." The companies are guaranteed a certain return, and the less they earn in the shape of gross receipts the more they get from the Government. To develope their traffic the companies must necessarily increase their working expenses. But for this they get no compensation. Hence such expenditure is a dead loss. The system seems too absurd to last; but it exists, and is eminently Turkish. The Smyrna-Aidin Company has no guarantee, and as it benefits by every increase in the traffic of its line it exhibits an exceptional prosperity. The Turkish Government is burdened by its guarantee system, and is supposed to have learned sufficient wisdom to abstain from giving any more guarantees, at least for a long time to come. For the present Turkey may be congratulated on having 1211¼ completed miles of railway in its Asiatic territory, out of 2285¼ miles for which concessions have been granted.

MUNICIPAL ELECTRICAL ASSOCIATION.

The first annual Convention will be held in London on the 10th, 11th, and 12th inst. The following programme has been issued :—

Wednesday, June 10th.—General meeting for the discussion of papers: Royal United Service Institution, Whitehall, S.W., 10.15 a.m. President's Address: "The Municipal Electrical Association and its Objects." Papers for discussion: (1) "Electricity Supply at 220 Volts," by A. S. Barnard, borough electrical engineer, Hull; (2) "Alternating Current Stations and High-voltage Lamps," by Harold W. Couzens, borough electrical engineer, Taunton; (N.B.—Papers Nos. 1 and 2 will be taken together for discussion); (3) "The Control by Municipal Authorities of Consuming Devices and the Wiring connecting them to the Mains," by C. H. Wordingham, city electrical engineer, Manchester; (4) "Electricity Works Records," by A. B. Mountain, borough electrical engineer, Huddersfield. Adjournment, 1 p.m. Visit of inspection to the works of the London Electric Supply Corporation, Deptford—chief engineer, Mr. P. W. D'Alton—4 p.m.

Thursday, June 11th.—General meeting for the discussion of papers: Royal United Service Institution, Whitehall, S.W., 10.15 a.m. Papers for discussion: (5) "The Cost of Electricity Supply," by Arthur Wright, borough electrical engineer, Brighton; (6) "Cable Specifications and Tests," by Joseph A. Jeckell, borough electrical engineer, South Shields; (7) "The Organisation of an Electricity Works Staff," by E. T. Ruthven-Murray, city electrical engineer, Worcester. Adjournment, 1 p.m. Reception by the Electric Lighting Committee of the Islington Vestry, Vestry Hall, Upper-street, Islington, 3.30 p.m. The Vestry Hall is within a few minutes' walk of the Agricultural Hall and of the Angel, at Islington. It is best reached from Charing Cross by cab or 'bus. Chairman of Electric Light Committee, Mr. S. Lambert. Discussion on paper: (8) "Combined Electric Lighting and Traction Plants," by John Hesketh, electrical engineer to the Government of Queensland, late borough electrical engineer, Blackpool, and John H. Rider, borough electrical engineer, Plymouth. Visit of inspection to the Islington Electricity Works, Eden-grove—within a few minutes' walk of the Vestry Hall—5 p.m.

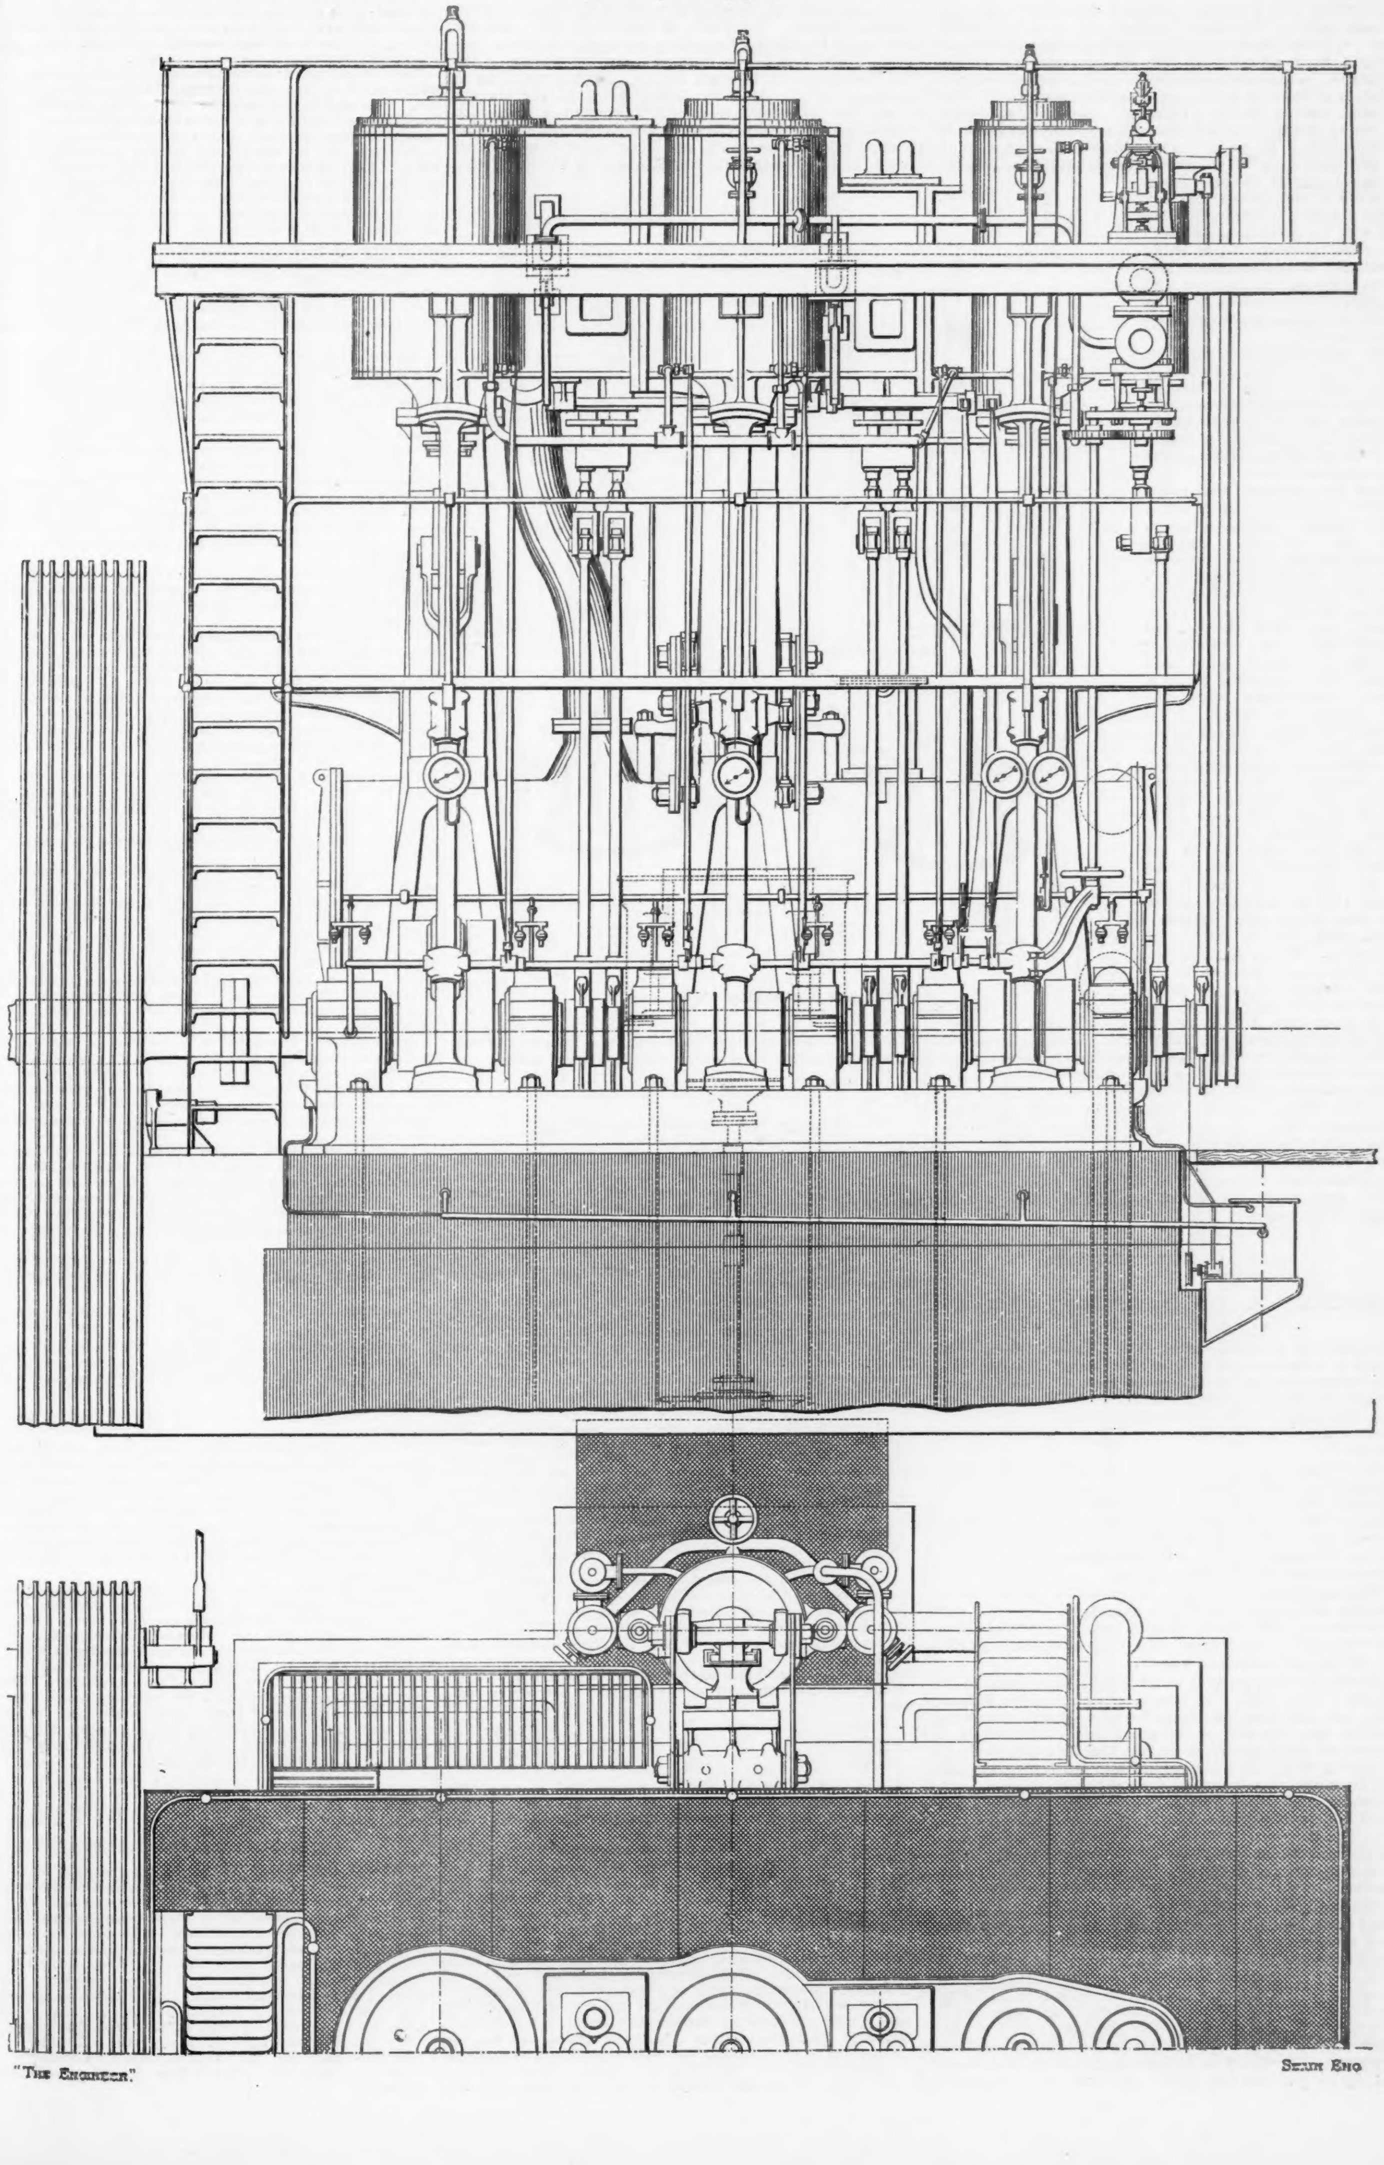
Friday, June 12th.—General meeting, for members and associates only: Royal United Service Institution, Whitehall, S.W., 10.15 a.m. Election of president, vice-presidents, three members of committee, officers, and place of meeting for the Convention of 1897; general business. Adjournment, 12 noon. Visit to Brighton by the 1.50 p.m. from Victoria or the 2 p.m. from London Bridge, arriving at Brighton at 3.15 p.m. and 3.20 p.m. respectively. Reception by the Electric Lighting Committee of the Corporation of Brighton at the Royal Pavilion, 4 p.m. The Mayor of Brighton, Alderman Blaker; the Chairman of the Electric Lighting Committee, Alderman Stafford. Discussion on paper: (9) "Extensions to Outlying Districts," by A. H. Gibbings, borough electrical engineer, Bradford. Visit of inspection to the Brighton Electricity Works, North-road, near the Pavilion, 5 p.m.

Naval Engineer Appointments.—The following appointments have been made at the Admiralty. Engineers: Walter May, to the Alexandra, additional for the Spanker and Edwin Bell, to the Vivid, to the Salamander. Assistant Engineers: Arthur P. L. Dupen, for the Alexandra, additional, for the Spanker.

300-I.H.P. TRIPLE-EXPANSION MILL ENGINES

MESSRS. J. COCHRANE AND CO., BARRHEAD, SCOTLAND, ENGINEERS

(*For description see page* 560)



"The Engineer." Swain Eng.

300-I.H.P. TRIPLE EXPANSION ENGINE.

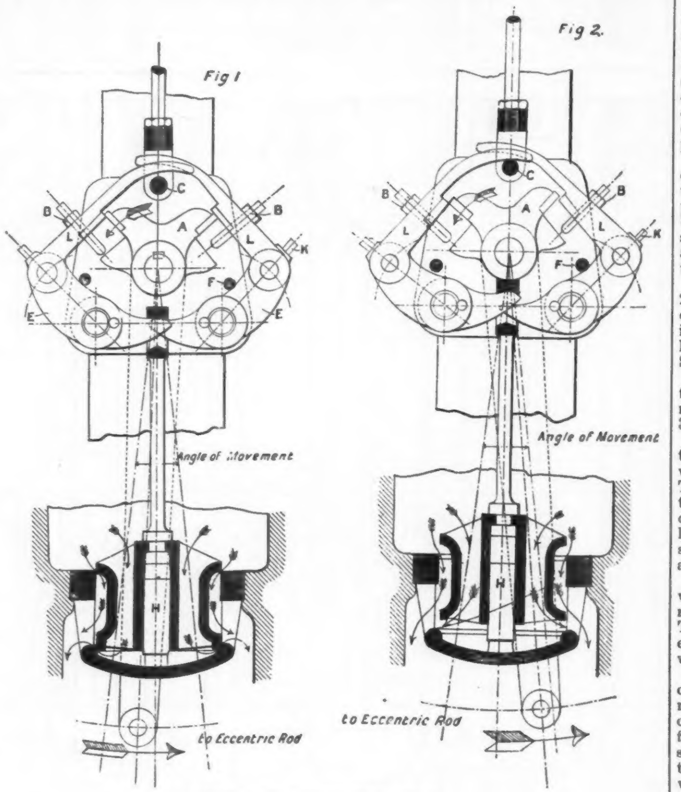
THE illustrations on pages 559 and 561 show a triple-expansion vertical mill engine made by Messrs. J. Cochrane, for a mill in the East.

It is fitted with a surface condenser, from which the back columns spring. The front columns are of polished mild steel. A piston valve is used for the high-pressure cylinder giving a fixed cut-off. To give an automatic cut-off the "Cameron" expansion apparatus is used, arranged to give a variation of speed of 1 per cent. from the mean speed. The essential features in the "Cameron" expansion apparatus are shown in Figs. 1 and 2; these clearly show the action of the apparatus. In order to put as little work as possible on the governor, stops B B are provided, which limit the amount of engagement of the steel faces on A and L, and prevent the end of the fingers L L coming in contact with the governor pin C until the valve is open, when it is practically in equilibrium. The valves of the intermediate and low-pressure cylinders are slide valves fitted with expansion plates having a fixed cut-off.

The usual practice of this firm is to fit such engines with Corliss valves and trip gear, at least on the high-pressure and intermediate cylinders, but it was particularly specified in the engine illustrated that the valves should be of the type described above.

The high-pressure and intermediate cylinders are jacketed with steam at boiler pressure, and are efficiently trapped. Metallic packing is used throughout. The low-pressure and intermediate cylinders are fitted with starting valves. The air, circulating, and feed pumps are worked from the intermediate cylinder by heavy mild steel levers. The circulating pump is placed immediately below the air pump, to which it is secured by three wrought iron stays. The level of the source of the circulating water determines the position of the circulating pump. The circulating water is forced through the lower set of brass condenser tubes, then through the upper set to the outlet. The power is transmitted to the mill by a grooved flywheel 15ft. in diameter, grooved for nine ropes 1¾in. diameter, fitted with barring gear. All accessories are most complete. The lubricant is pumped to the main bearings by an oil pump driven from the main shaft; the oil is drawn from a tank, the excess being returned thereto and filtered. Access to the various parts is obtained by middle and upper stages, which are protected by polished wrought iron hand-railing and columns. The boiler pressure is 160 lb. per square inch; revolutions ninety; cylinders 11½in., 18¼in. and 30in. by 36in. stroke; indicated horse-power 300. This engine has been working now for three years with excellent results.

Two Lancashire boilers 30ft. by 7ft. 6in., for 160 lb. pressure per square inch, complete with all steam pipes and economiser, were supplied with this engine and set to work by Messrs. J. Cochrane.



CAMERON'S EXPANSION GEAR

MARITIME CANAL OF THE LOWER LOIRE.

ACCORDING to a recent report of the United States Vice-Consul at Nantes on the trade of that port, notwithstanding unfavourable circumstances and the general crisis for some time in maritime commerce, transit by the canal has from the commencement caused an increased activity which seems destined to make Nantes one of the principal ports of France.

The object of the canal was to take the place for heavy navigation of that section of the river comprised between the extremity of the dykes—*à la Martiniere*—and Paimbœuf, in which are the highest banks and the most difficult channels to keep open. Work was commenced on the canal in 1882, and on September 1st, 1892, it was delivered over to navigation and completed the following year.

The canal proper is 9 miles 635 yards in length, and is closed at each end by locks 328ft. long, 122ft. wide, and with an entrance of 59ft. width. Close to each of these locks there is a basin 1148ft. 4in. long by 492ft. 1½in. wide, which permits the waiting and passing of vessels.

The width of the canal at water level is 180ft., and at the bottom or floor 90ft. At points one-third of the distance from each end there are docks for the passage of meeting vessels. On each side of the canal there is a towpath of broken and roller pressed stone, and also numerous stocks for embarking or disembarking agricultural produce or animals. The draught of vessels passing through the canal is constantly increasing, and although in its normal state the canal is supposed to furnish largely 19ft. 8¼in. of depth, a vessel drawing 21ft. 1¾in. has successfully passed, and with the aid of water drawn from the feeder—*l'achenean*—the level can be raised so as to permit during full tide the passage of a vessel drawing 24ft. 6in.

The number and tonnage of vessels passing through the canal have constantly increased from its opening to the present time. In 1892—four months—the figures were 123 vessels and 39,090 tons; in 1893, 595 vessels and 206,313 tons; in 1895, 791 vessels and 334,500 tons. The average tonnage has risen from 325 tons in 1892 to 423 tons in 1895. Although the canal has given satisfaction as to depth of water and its quick, easy, general working, the channel above the canal between Le Pellerin and Nantes is less satisfactory, although dredging has produced an improvement in access to the port. During the past two and a-half years, with very rudimentary machinery, the depth of the channel has been increased nearly 4ft., and with the proposed more powerful dredgers there will be entire satisfaction as to depth.

It was easier than at first anticipated to obtain a depth of 18ft. at low tide and still water, but it has been more difficult to maintain this result at all times of the year and under all circumstances. The means at disposal of the engineers have proved insufficient to remove promptly the sand bars formed by floods or ice, an example being the closing of the river for navigation through ice for nearly a fortnight in February, 1895. After the breaking up of the ice the channel was inaccessible to vessels drawing more than 16ft. of water for several days owing to defective dredging. This proved a salutary lesson, as the Chamber of Commerce of Nantes, in conjunction with the Ministry of Public Works, took steps to procure at once the appliances necessary to keep the channel always open with a 20ft. draught of water.

TESTS OF AMERICAN RIFLES.

THE Legislature of New York State in 1895 passed a law creating a Commission to examine and test such rifles of American invention and manufacture as might be submitted to it, with a view to the selection of a new rifle for the National Guard—militia—and some interesting trials have recently been made by this Commission, which is composed of Dr. R. H. Thurston, the Professor of Mechanical Engineering at Cornell University; Colonel A. D. Shaw, and Mr. E. W. Bliss, a manufacturer of machinery for ordnance and other purposes.

According to the report, the first gun tested was made by the Savage Repeating Arms Company, of Utica, being a hammerless magazine repeating rifle, with 28in. barrel, 0·30in. calibre, weighing 9¼ lb. without the sword bayonet. It is a lever action, the magazine, to hold five cartridges, being in the centre of the frame immediately behind the breech. There is no wide opening through the framework, which is the weak point of the Winchester rifle. The lever operating the breech-block works easily and smoothly. It can be used either as a single loader or as a magazine rifle. The magazine holds five cartridges, in addition to the one in the barrel. When used as a single-loader, an automatic cut-off prevents the magazine cartridges from entering the barrel. In this way the reserve ammunition is ever ready for use when a sudden emergency arises. No clip or case of any kind for the cartridges is used. They are simply slipped in on top, and are automatically ejected. This can be done so rapidly that the entire six are in the air together. The rifle is asserted to have a range of 2000 yards and a point blank range of 500 yards, with a trajectory of only 4ft. It was rejected by the Government when the Krag-Jörgensen rifle was selected for the United States Army, but has been improved upon since then. It holds the record for ten shots, fired at 100 yards in twenty-three seconds. The entire charge of six shots can be fired in less than four seconds, and 700 shots have been fired continuously.

The first test was fifteen shots at 200 yards, as a single-loader, by the manufacturers' expert with the rifle. The scores made were:—

Savage	4	4	3	3	3	5	4	4	4	4	4	3	3	4	4—56
Crane	4	2	3	0	4	3	4	4	4	3	4	4	3	5	3—50
Savage	4	3	4	4	4	4	4	3	3	4	4	4	3	0	4—52
Crane	3	5	4	4	4	4	4	5	4	3	5	0	4	4	4—57

Crane shot off-hand, while Mr. Savage used a rest. The mechanism was then carefully examined and the entire six shells were ejected with so much rapidity that the whole lot were in the air together.

Next came the test of endurance. Four hundred shots were fired at close range into a box filled with sand, the sides being of seasoned birch, 3in. thick. The shots were fired in rounds of fifty shots, with ten minutes' intervals to allow the gun to cool. The first round was fired, single loading, in three minutes; second, three; third, three; fourth, three; fifth, three and a-half; sixth, four; seventh, three; eighth, two and three-quarter minutes. The weapon was then closely examined and pronounced to be as good as at the start. Defective cartridges were then used to see if the block or extractor would jam, but they worked splendidly.

Next came the test of excessive and defective cartridges. The powder used was Wetterau smokeless powder, made at Wetterau in Belgium. The service charge is thirty-six grains, and this test called for a charge of forty grains. When the powder was weighed on the scale provided, it was found to be much more than the shell would hold. Mr. Savage thought the scale was wrong, and, with Private Crane and Secretary Abell, went to a druggist's and had the charge weighed. It was found to be seventy-five grains, enough probably, if it could have been put in the shell, to cause an accident and possibly burst the gun. Three of these charges were fired with a lanyard, the gun remaining uninjured. In one of these the primer was blown out of the shell. The next test was made with defective cartridges, the primers being thinned to a mere shell, so as to allow gas to escape. The shells were badly bulged, but the mechanism remained uninjured. The primers were burst, but the gun was as good as new.

The rifle had then fired over 470 shots, and as it had been cooled with water it was necessary to clean it before applying the sand test. This consists in placing the rifle in a box connected with a large bellows. Midway is a funnel containing fine sand. This is blown with great force into the box and permeates all the working parts of the rifle, the barrel being stopped to avoid injury to the rifling. The idea is to give the arm such a test as it would undergo in a long and dusty march. After each test six shots were fired by Mr. Savage, and the rifle behaved admirably. He was not allowed to clean the weapon except with his hand and by blowing the sand out just as a soldier in action would. The test was a severe one, and was made in these four methods, six shots being fired after each test. Only the first two were used at the Government trials. (*a*) Magazine empty, breech closed; (*b*) magazine full, breech closed; (*c*) magazine empty, breech open; (*d*) magazine full, breech open. One of the great features of this gun is that it is the only lever magazine rifle that can be operated from the shoulder position.

The next to be tested was the Briggs-Kneeland rifle, but several of the cartridges did not explode at the first pull of the trigger, the spring being too weak. The rifle is loaded with five cartridges placed in a metal frame, which is slipped down through the frame behind the slot that takes the cartridge when the gun is used as a single loader. In the magazine test for fifteen shots, Knapp scored 59 and Crane 53. With the exception that some cartridges refused to explode, the gun behaved well.

The cartridge used was the Lee navy, which has a diameter of 23·006, while the Army rifle has a calibre of 30·003. The pressure on the former is said to be something like 60,000 lb. to the square inch; on the latter, between 35,000 lb. and 40,000 lb. This rifle had a much more vicious bang and a far harder recoil than the Savage rifle.

Next came the endurance tests. Each round of fifty shots was fired in the following time, in minutes and seconds, with ten-minute intervals for cooling:—4.00, 4.00, 4.00, 3.20, 3.10, 3.18, 3.20, and 4.00.

The weapon stood the firing of these 400 shots well. The defective cartridge test came next. It was far from satisfactory, and was finally rejected by the Commission, and must be tried again. The idea is to thin down the primer so that the needle shall penetrate it and allow the gases to escape and so damage the mechanism or have a chance to injure the operator. They were fired with a lanyard. In neither case did the primer burst, and the Commissioners held that the requirement had not been fulfilled, and that a new test would be necessary.

The testing with excessive cartridges came next. The shots were fired with a lanyard, the shells, carrying forty grains of rifleite powder instead of the regulation charge of thirty-six grains. They went off with a terrific bang. The first one was difficult of extraction, indicating expansion of some of the parts, but the gun was apparently uninjured.

The Winchester rifle was the next, and closely resembled the ordinary Winchester sporting rifle. It carries five shells in the magazine, loading from the top. When the magazine is full it cannot be used as a single loader unless first one shot is fired from the magazine. If a shell is put in the breech slot, the weapon is at once jammed, unless there is one shell out of the magazine. The movement seems to work hard at two points, where there are apparently dead centres of motion to be overcome, which makes the action hard. There would be no difficulty in altering the gun so that the magazine would hold either six or ten cartridges.

The Winchester tested had a barrel 28in. in length of nickel steel, there being 4½ per cent. of nickel in the composition, and it is said that nothing else would stand the smokeless powder used. This is made at Wilmington. It is a nitro-glycerine powder, and not so smokeless as either the Wetterau or rifleite powders. Being weaker, 39 grains of it were used, as against 36 grains used in the other rifles.

In general appearance the gun exhibited does not differ in its action materially from the sporting rifle of the same makers. The magazine to hold the cartridges is below the breech, not tubular, as in the ordinary gun. The lever has two arms, which pass on each side of the magazine, connecting, of course, above and below. The bolt is the same in appearance as in the old weapon, with a hammer behind it.

The test began as usual by the company's expert firing fifteen shots at the 200-yard target. Then Private Crane followed. The score was:—

Van Dyke	4	3	4	4	4	4	4	4	5	3	4	4	5	4	5—61
Crane	4	5	4	4	5	3	3	4	5	4	5	5	4	5	4—64

This was good shooting, Van Dyke bracing against the rack, Crane shooting offhand. The gun kicked harder, according to Mr. Crane, than any other tried so far. The firing as a magazine gun came next, the score being:—

Van Dyke	4	4	3	4	3	4	5	4	4	5	5	5	5	4	4—63
Crane	4	2	2	4	4	4	2	3	3	3	4	4	5	4	5—53

This was a great falling off in Crane's work, but the gun had become so heated that the radiation absolutely obscured the target. The gun was allowed to cool off in the last string, and his shooting at once came back to his former average. In the fourth shot fired by Crane in the first round the sight was blown out, apparently by an escape of gas from the breech, but it could not be traced.

The endurance test followed. The time in minutes and seconds was:—4.30, 4.00, 5.00, 4.30, 3.45, 4.00, 3.45, 2.35. The gun stood the test well.

The test with defective cartridges came next. Mr. Van Dyke did not use a lanyard, but fired from the shoulder, braced as usual. At each shot, the escaping gas flashed up in a flame from the breech, but the gun and its handler were uninjured.

In the excessive charges test the same powder as used in the other tests was used. The gun was uninjured.

The rifle was then taken apart and assembled again. The same tests were then taken up, and the following scores were made under these conditions:—Fired—six shots after each exposure to dust blast during one minute. (A) Magazine empty, breech closed; (B) magazine full, breech closed; (C) magazine empty, breech open; (D) magazine full, breech open.

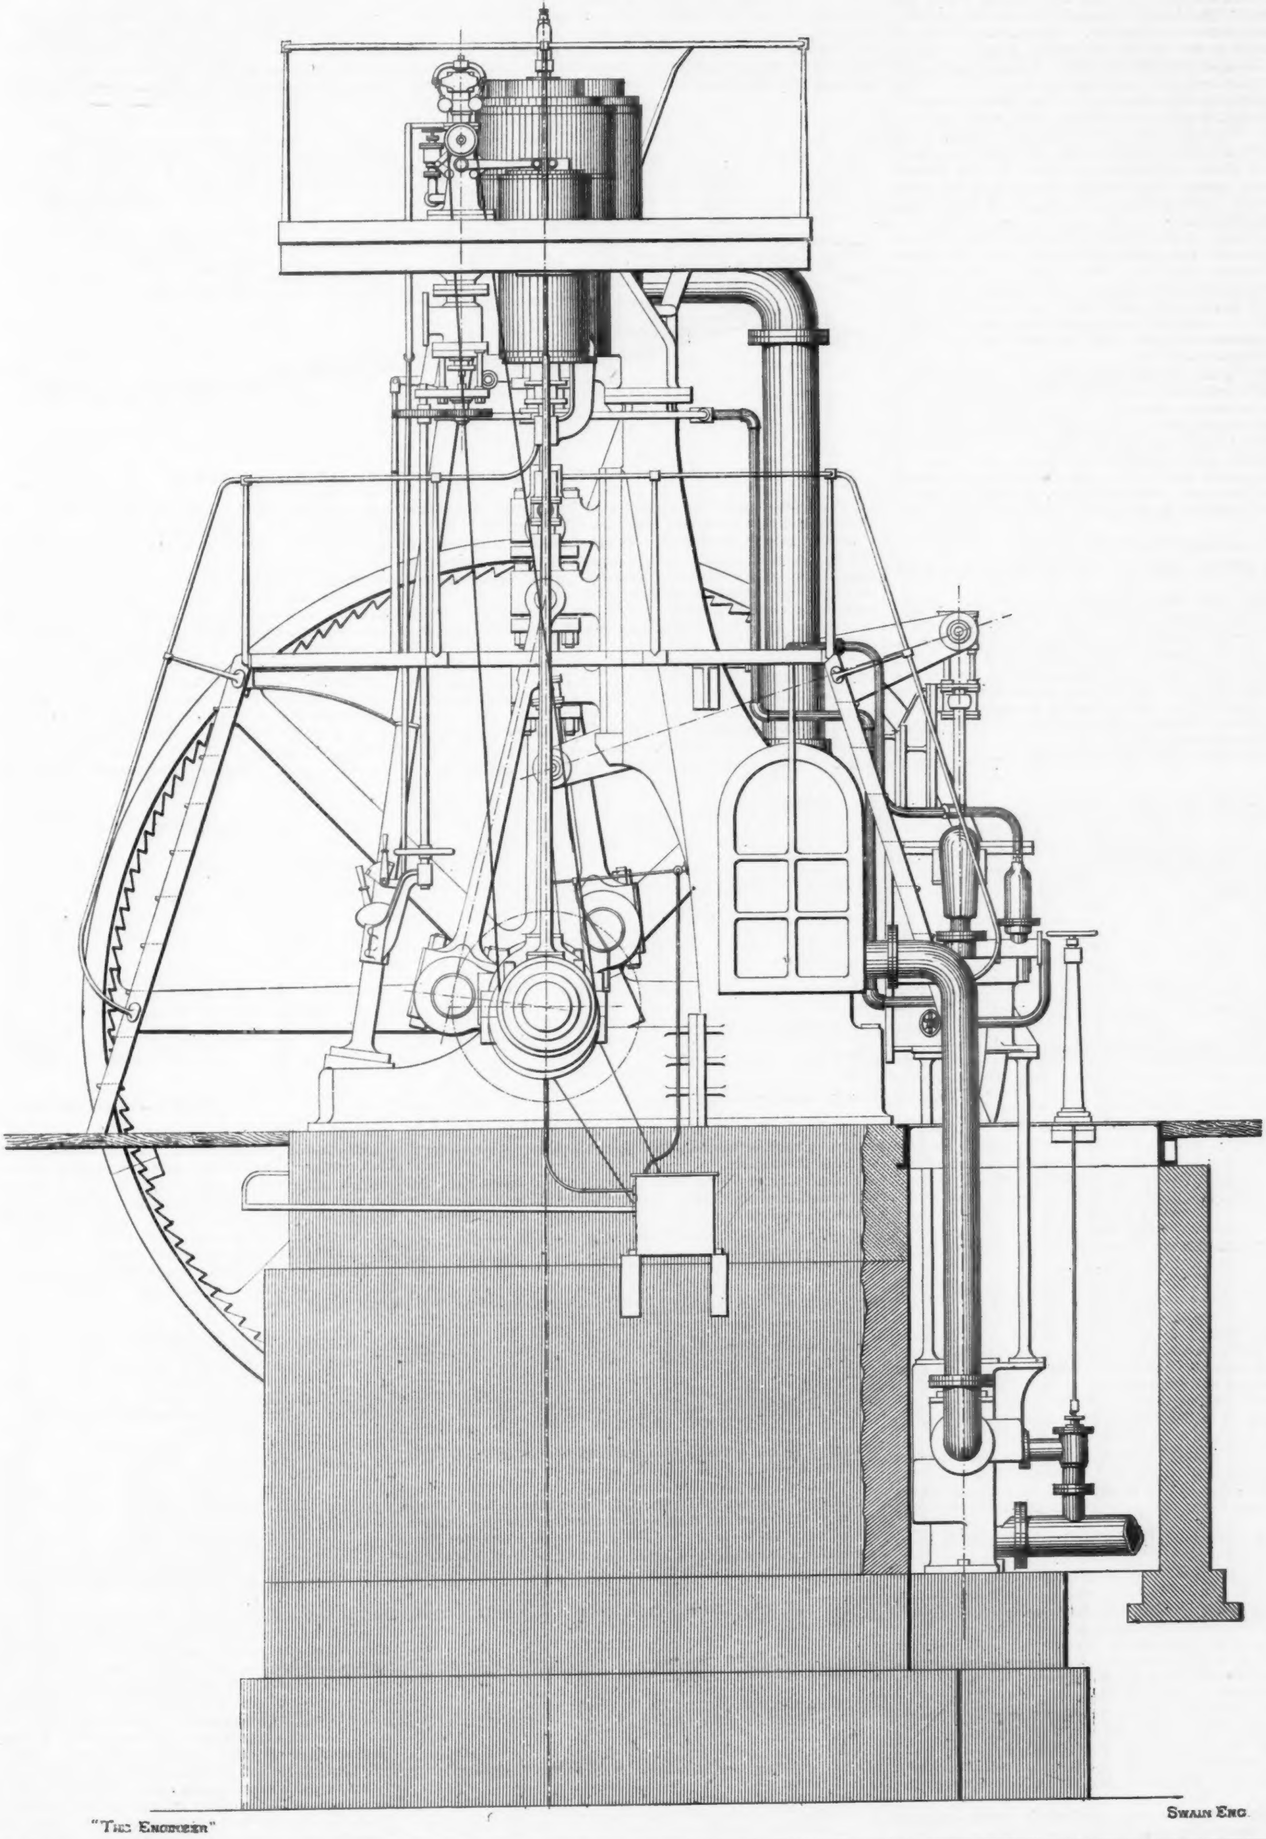
A	4	3	4	4	4	4—23
B	5	4	5	5	5	4—28
C	4	4	4	4	4	4—24
D	3	3	4	4	3	4—21

RAILWAY ACCIDENTS IN AMERICA.—The record of accidents for April includes 21 collisions, 72 derailments, and one other accident, a total of 94 accidents, in which 28 persons were killed and 104 injured. These accidents are classified by the *Railroad Gazette* as follows:—Collisions: Trains breaking in two, 4; misplaced switch, 2; miscellaneous, 10; unexplained, 5; total 21. Derailments: broken rail, 3; loose or spread rail, 6; defective bridge, 5; broken wheel, 1; broken axle, 9; broken truck, 1; fallen brakebeam, 1; failure of drawbar, 1; misplaced switch, 2; bad switching, 2; bad loading, 1; runaway train, 1; derailing switch, 1; animals on track, 1; landslide, 4; washout, 2; wind, 1; accidental obstruction, 3; unexplained, 27; total 72. Other accidents: Tornado, 1. Total number of accidents 94. Thus derailments constituted nearly 77 per cent. of the whole, and of these over 37 per cent. were unexplained.

300-I.H.P. TRIPLE-EXPANSION MILL ENGINES

MESSRS. J. COCHRANE AND CO., BARRHEAD, SCOTLAND, ENGINEERS

(For description see page 560)



THE LIVERPOOL DOCKS.

We last week called attention to the large addition to the landing-stage; we now chronicle the opening of a new branch to the Canada Dock and the widening and deepening of the lock entrance to the same dock. The new dock is almost ready for use throughout its extent, and the little that remains to be done, viz., deepening, is being rapidly executed by one of the Dock Board's powerful dredgers.

The Canada Dock was built about forty years ago by Mr. Jesse Hartley, the Mersey Dock Board engineer, with an entrance lock 500ft. long and 100ft. wide, in order to accommodate paddle-wheel steamers then used for the Trans-Atlantic service. These reached their climax in the famous Cunarder Scotia, which was long commanded by Captain Judkins, was the last of the paddle-wheel steamers so employed. When paddles gave place to the screw propeller it was thought that these wide entrances were no longer necessary, but the enormous increase in the length of ships has necessitated an increase in beam, and 100ft. openings have been built for some years. The draughts now required were unnecessary thirty or forty years ago, and the sill of the Canada Lock, which was for a long time the deepest on the Liverpool side, was laid 7ft. 9in. below O.D.S.; this has now been deepened to 14ft. below O.D.S., making this entrance the deepest on the Dock Estate; deeper by 2ft. than the entrances to the Alexandra group of docks, which were opened by the Prince of Wales in 1881, and which have entrances at the same level as the deep water docks at Birkenhead. It should be stated that the entrances to the Herculaneum, Harrington, and Toxteth Docks, at the south end, have already been deepened to the same level. The water in the group of docks from George's Pier to the south is impounded over low neap tides, and any loss made good by pumping from the river. By this means the effective depth of the docks is maintained at the depth of the lowest sills over which they can be approached, which is, as we have seen, 12ft. below datum. The docks at the north end are excavated below the level of their gate sills, so that pumping for this purpose has hitherto been unnecessary.

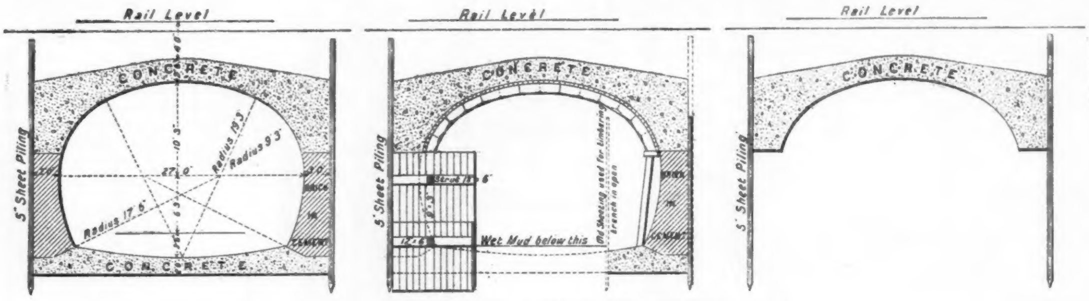
The entrance from the river into the Canada Basin has previously been widened from its original width of 250ft. to 390ft.; the basin has a water area of 9¼ acres. This forms the vestibule of the Alexandra as well as of the Canada group of docks. The Canada Dock has an area of nearly eighteen acres, and the branch will add another twelve or thirteen acres. Along the north side is a single-storey shed, 125ft. wide, while on the south a double-storey fireproof shed, 95ft. wide, has been constructed. At present the dock is entered on the north side only, but a new south entrance to the Huskisson Dock is in hand. When all is complete the water in the Canada and Huskisson systems of docks will be impounded, and there will be entrances to the Mersey for the largest steamers from both north and south.

The value of the new branch dock has been quickly demonstrated, for already the north and south sides are appropriated for the use of the White Star Line of steamers and the west side for Cunard steamers. The increased depth of entrance gives much more freedom of navigation. It provides 29ft. 6in. at mean high water, and with vessels drawing nearly 30ft. constantly plying from the port, the advantage of this extra depth is obvious.

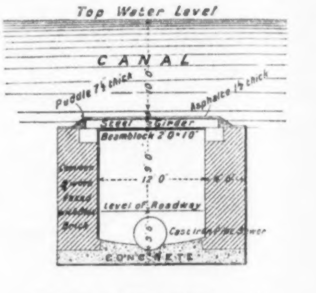
The level of the sills of the deepest docks was until recently about or a little below the level of the Mersey Bar; now the deepest entrance is 10ft. above the Bar, and the berths at the landing-stage are the only ones capable of accommodating deep-draughted vessels on certain tides. This points to deeper entrances being required ere long. These can be obtained by lowering the sills of the Birkenhead Docks or extending the Liverpool Docks to Dingle, a little higher up than the most southerly dock on the Liverpool side of the estuary.

THE DALMUIR AND CLYDEBANK RAILWAY.

Some little time back—The Engineer, August 16th, 1895—we laid before our readers some account of the construction of the tunnel for the passage of the Dalmuir and Clydebank Railway, beneath the North British Railway near Dalmuir, a work which had to be executed under exceptional conditions, which we fully detailed. As the entire line is now rapidly approaching completion, and presents several additional features of interest, we now purpose in brief outline dwelling on the extension as a whole.



COVERED WAY BENEATH THE RAILWAY



TUNNEL UNDER CANAL

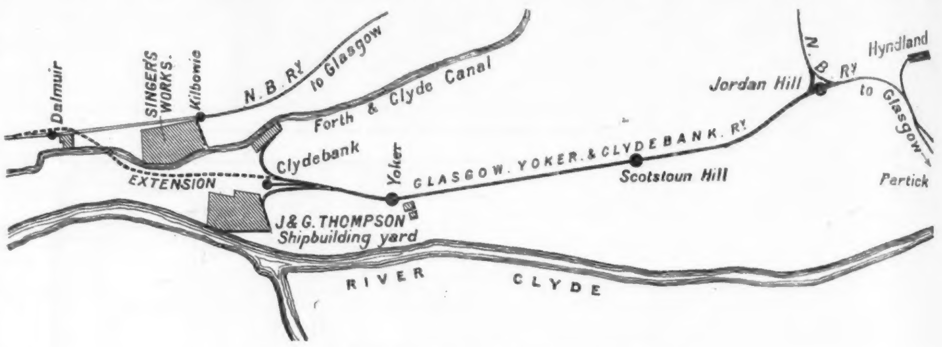
The Glasgow, Yoker, and Clydebank Railway was authorised by Parliament in 1878, and was opened for traffic in 1882, the line being worked by the North British Railway Company. It commences at the Stobcross branch of the North British Railway, about 3½ miles west of Queen-street Station, Glasgow, and passing Yoker, terminates at Clydebank, a distance of some 3¾ miles. The immediate reason for the construction of the line was the removal in 1872 of Messrs. James and George Thomson, the well-known shipbuilders from Govan to Clydebank.

So far back as 1878, the original promoters had purposed carrying the line on to Dalmuir to form junction with the North British Railway, and gain access to the Vale of Leven and the Clyde, but the Caledonian Railway Company, as owners of the Forth and Clyde Canal, raised difficulties, and the promoters had no choice but to make Clydebank their terminus. A year after the opening of the Glasgow, Yoker, and Clydebank Railway—viz., in 1883—efforts were again made to extend on to Dalmuir, but the same opposition being again encountered, the Bill was withdrawn. Seven years later—viz., in 1890—in connection with the passage through Parliament of the Lanarkshire and Dumbartonshire Railway Company's Bill, the Caledonian Railway Company withdrew its opposition, so far as the principle of extension was concerned.

In 1892 the Glasgow, Yoker, and Clydebank Railway sought the requisite powers for extension, but again failed to obtain them, its proposals for passing beneath the canal being deemed defective. In 1893 success was at length secured, the company undertaking to divert the canal, and not to tunnel beneath it by means of air pressure and shields.

The line as now constructed, though only 1 mile 7 furlongs 6 chains in length, presents difficulties of most unusual character, and in this short length a very large amount of arduous and difficult work has been executed. The district has been much built on of late years, whilst the crossings with the Lanarkshire and Dumbartonshire line—to be opened during the current year—have added to the difficulties encountered, amongst which the passages beneath the Forth and Clyde Canal and the North British Railway figured prominently.

Turning now to some short account of the route selected, the extension leaves the existing Glasgow, Yoker, and Clydebank line to the east of Clydebank station, and, passing north of it, ascends by a gradient of 1 in 70 until an elevation is reached sufficient for crossing the Lanarkshire and Dumbartonshire line—occupying the bed of the arm of the canal at this point—and the various streets now encountered, the bridges of which call for no special comment. On approaching the Forth and Clyde Canal, after gradients of 1 in 260, 1 in 160, a short level portion, and a further descending gradient of 1 in 56, passage is made beneath the Lanarkshire and Dumbartonshire Railway, which is carried over by a skew steel girder bridge; after which on a gradient of 1 in 1000, falling to 1 in 80, the canal is passed under on the level, and with ascending gradients of 1 in 88, the North British Railway is reached and tunnelled, junction being made with the North British Railway Company's rails to the west of Dalmuir station by rising gradients of 1 in 260, 1 in 88, and 1 in 487, two roads to the north of Dalmuir station being carried above the new line. The earthwork involved in the undertaking consists of 160,000 cubic yards of cutting and 96,000 cubic yards of banking. The arduous nature of the work may be gauged from the fact that on this short line no less than eighteen bridges occur, including the covered way near Dalmuir, under the North British Railway. Steel plate girders, with either trough flooring or cross girder and buckle plates, and masonry abutments and wing walls, are the type adopted.

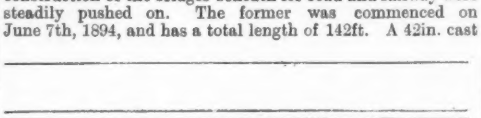


ROUTE OF THE DALMUIR AND CLYDEBANK RAILWAY

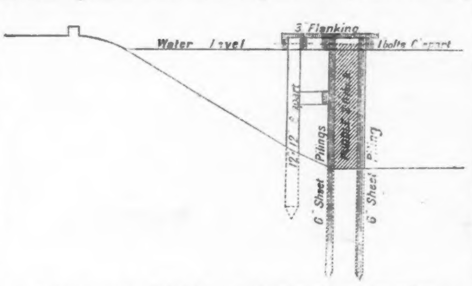
All superstructures were constructed by Messrs. Alexander Findlay and Co., Parkneuk Ironworks, Motherwell, N.B.

Passing now to consider the canal diversion, which forms one of the salient features of interest of the undertaking, and which has a length of 440 yards, two bridges occur, one carrying the canal over the road diversion, the other carrying it over the new railway. The earthwork cutting and banking involved in the diversion was 13,000 cubic yards and 36,000 cubic yards respectively. The puddle walls, which were 3ft. thick, were formed from boulder clay taken from an adjacent cutting, turned over two or three times and kept well watered, being subsequently left for a few days to get properly soured before being taken to the banks as required. The width between the puddled walls is 66ft. 6in., giving a width on water level of 62ft. The canal is 10ft. deep for a width of 27ft. in the centre, making the inclination of the sides 1¾ to 1. Except where the formation is on forced ground, where the puddle is made 2ft. thick it has a uniform depth of 12in. throughout.

Simultaneously with the canal diversion operations, the construction of the bridges beneath for road and railway were steadily pushed on. The former was commenced on June 7th, 1894, and has a total length of 142ft. A 42in. cast iron pipe is laid beneath the roadway and the foundations being in a water-logged alluvial deposit of sand and gravel. The foundations were 18in. thick, and of concrete, the sewers resting on the concrete invert, the abutments, which were 4ft. 6in. thick, being formed of common brick in cement, with blue brick facing. The above illustration gives the leading dimensions—a clear span of 12ft., and a headway of 9ft. The canal is carried on steel girders 1ft. deep, spaced 3ft. apart from centre to centre, and connected by 9in. jack arches of blue brick, having a 3⅝in. rise. The haunches were filled with concrete, and two layers of asphalte, each ¾in. thick, were covered by the puddle already described, and 7½in. thick over the roadway.



GIRDERS CARRYING CANAL

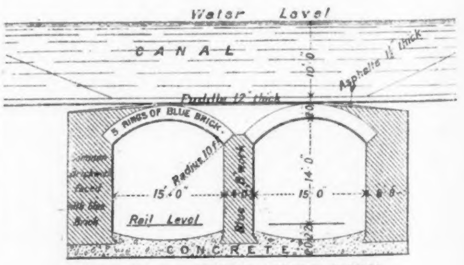


PILING AND PUDDLE WALL CANAL DIVERSION

We pass now to the railway bridge under the canal, which is entirely of brickwork and 260ft. long, consisting of two arches to save headroom, each 15ft. span. Two abutments, each 6ft. thick, and a 4ft. pier, the side walls, whose foundations being in wet mud caused considerable difficulty, were formed in trenches 18ft. deep by some 12ft. in width. The abutments are of common brick with blue brick facing, whilst the centre wall is entirely of blue brick in cement. The arches are formed by five rings of blue brick in cement, giving a thickness of 2ft., the haunches being built up with ordinary brickwork in cement. Two layers of asphalte, each ¾in. thick, completed the structure.

On completion of the bridges the cofferdams were commenced, each being formed of 12in. by 12in. bearing piles 6ft. apart. The piling frame was then carried on planking resting on these piles and on the towing path, and thus two rows of 6in. sheet piling, 15ft. to 20ft. long, were driven, a space of 2ft. being left between them for the puddle. The water was then pumped out, the old banks removed, and connection made with the deviation; the whole of the operations occupying less than a year. Four days after the admission of the water a leak was discovered, due, it was subsequently found, to the puddle having insufficient bottoming on the site of an old hedge—a defect which was speedily remedied. The piles were subsequently withdrawn by a pitch pine lever 12in. by 12in. and 17ft. long, four or five men working a hand winch with a 1in. steel wire rope, led through pulleys to the lever. By this means as much as 15ft. of the dam was removed per day. The covered way under the North British Railway, near Dalmuir station, has been so fully described and illustrated in our columns—The Engineer, August 16th, 1895—that it is unnecessary for us to again describe this salient feature of the new extension railway. Suffice it to add in continuation of our description of last autumn, that the arch stood nine months before the underpinning was commenced and executed in 6ft. lengths, considerable difficulty being experienced with water. It will be seen from the engravings that after the sheet piling was driven, the top earth was excavated, and the concrete arch formed as shown. The sides were afterwards built by partial excavation and underpinning.

The Portland cement used on the undertaking was required to weigh not less than 112 lb. per imperial—striked—bushel, and to bear a tensile strain of not less than 400 lb. per square inch after seven days' immersion in water. The concrete was formed of one portion of Portland cement to one of sand and five of broken stone, the mortar being composed of one part of Portland cement to three parts of sand. Steel rails weighing 84 lb. per yard, with 40 lb. chairs, are employed, there being twelve sleepers to each 30ft. rail. The engineers are Messrs. Simpson and Wilson, C.E., of Glasgow; Mr. James Andrew being resident engineer. The contractors are Messrs. Robert McAlpine and Sons, of Glasgow.



SECTION OF BRIDGE UNDER CANAL

Our illustrations, which deal with the canal and railway crossings, and the more salient features of interest of the undertaking, are self-explanatory, and being fully dimensioned, need no further comment at our hands.

Shipping Facilities at Natal.—Captain Froud, the Secretary to the Shipmasters' Society, writes:—"It may interest the shipping community to know that steamers of 5000 tons gross, 400ft. long, and drawing up to 20ft. of water, have lately entered the harbour of Natal, South Africa. The new dredger has done excellent work since she commenced operations early in February. The greatest difficulty at the port now is want of accommodation inside the harbour to meet the demands of the great increase of trade." The dredger referred to is the Octopus, constructed by Messrs. William Simons and Co., Renfrew.

RAILWAY MATTERS.

The Baldwin Locomotive Works have an order for sixty additional locomotives for Russia.

On Whitsun Monday the Great Eastern Railway Company conveyed, to stations within twenty miles of London, no less than about 132,000 passengers.

In the Chamber of Deputies, Rome, on the May 29th, the Duke of Sermodeta submitted the Italo-Swiss Convention with regard to the projected Simplon Railway.

Some of the famous 8ft. Great Northern single-driver engines will shortly be running with domes. Some new engines are being built with slightly larger fire-boxes. The old form of Great Northern Railway "pull-out" regulator is to be retained.

Five new engines have just been turned out of the Gateshead shops of the North-Eastern Railway, for the Scotch traffic, having four coupled drivers 7ft. 7¼in. diameter, and cylinders 20in. by 26in. We hope to describe these engines more fully later on.

Light rails for Japan are being manufactured at the Bay View Mills of the Illinois Steel Company, near Milwaukee, Wis., and will be sent to New York to be shipped by steamer to Japan. The order comes through the China and Japanese Trading Company The contract price is said to be 21·36 dols. per ton.

It was expected that the contracts for the 5000 cars to be built for the Baltimore and Ohio Railroad will be given out before the first of the month. The company invited bids on 5000 cars, 1800 of which are box, 1800 solid bottom coal, 400 drop bottom coal, and 1000 drop bottom coal with coke racks. It is rumoured that instead of 75 new locomotives the company will purchase 100.

An American contemporary says a street car with pivoted seats is being tried on the Grand-street and Desbrosses-street line in New York city. There are ten chairs on each side, facing towards the front of the car, the seats being supported on brackets. This enables seated passengers to avoid having their feet stepped on by those who are standing on or walking through the car. The seats are reversed at each end of the route by means of a lever. The car was built at the shops of the Dry Dock and East Broadway Railway Company.

The development of Staten Island as a residential district of New York is the purpose of several syndicates, which propose to extend the electric railways, build new roads, put faster ferryboats on the New York line, and establish new ferries to Elizabethport, Bayonne, and Brooklyn. *Engineering News* says two companies are already building electric railways extending back from the towns on the bay shore of the island. One of these is the Midland Electric Railway Company, and the other is the Staten Island Electric Railway Company.

In answer to a question in the House of Commons on Monday by Mr. Massey Mainwaring concerning the Snowdon Railway accident, Mr. Ritchie said the engineers are of opinion that the accident was caused by the locomotive mounting the rack, probably in consequence of a subsidence of the permanent way, caused by the melting of snow in a cutting. As the line was not constructed under any statutory authority, the provisions of the Railways Acts as to inspection do not apply. On the recommendation of the company's engineers, no passenger traffic has been carried since the date of the accident, and none will be carried pending the adoption of certain additional precautions suggested by the engineers to prevent the engine mounting the rack.

Although the East and West Coast Companies have found it advisable to run third class as well as first-class cars, the Great Western Railway is just starting first-class only. Wouldn't it be better, says *Moore's Monthly Magazine*, to once and for all vestibule the cars forming the train, provide a passage along all, and attach a refreshment or dining car on convenient sections of the run, and allow all passengers, irrespective of class, the opportunity of lunching or dining *en route?* With the present restrictive arrangements we are inclined to think the cars cannot be such a financial success as they would be if all limitations were removed. But it is the same with dining cars as with hundreds of other things. The new dining cars of the Great Western Railway are 59ft. 3in. long and 8ft. 6in. wide, on two six-wheeled bogies; weight, 27 tons 14 cwt. Dining accommodation is provided for sixteen people. The new service is between London and Cardiff.

Compressed gas for lighting railway cars is to be carried in 2in. pipes through the streets of Washington, D.C., to connect the works of the Pintsch Compressing Company with the stations of the Baltimore and Ohio Railroad, Baltimore and Potomac Railroad, and Southern Railway, and also to the river front, where it will be used for charging illuminated buoys for the Potomac River navigation. In reporting the Bill, Senator McMillan, of the committee on the District of Columbia, alluded to the project as follows, an American contemporary says: "Pintsch gas is used for lighting railway cars and buoys. The object to be gained is the lighting of the railway mail cars starting from Washington, thus doing away with the oil lamps, so dangerous in railway mail cars especially; also the furnishing of gas for lighted buoys on the Potomac. The Pintsch gas is in use all over the country, and there is no experiment in the matter. Indeed, the Bill simply provides for a commercial necessity."

From statistics just issued in Chicago, it appears that ten years ago there were but four tramway companies in Chicago, capitalised at 11,437,000 dols., and working a street mileage of 90 miles. To-day there are twenty-nine distinct corporations engaged in local transportation business, having an aggregate capitalisation of 187,208,000 dols., and operating 342 miles of street mileage. Of the four systems in existence ten years ago three were worked entirely by horses, the four using both cable and horses. Now the horse car has practically disappeared from Chicago, the motive power at present being:—Surface roads—electric, 255 miles; cable, 42 miles; horse, 18 miles. Elevated roads—electric, 15 miles; steam, 11 miles. In addition to the roads now completed, construction work is rapidly progressing upon five surface and elevated roads, all to be worked by electricity, and which will, when completed, increase the total city mileage to 400 miles. Against these figures, as the *Times* remarks, it is interesting to place the statement that London has less than three miles of mechanically worked tramways, while the total street length of tramways is only 136 miles, all worked by horse power.

A fair and impartial demonstration of the possibilities of compressed air for street car propulsion is yet to be made. In this field compressed air can present no arbitrary claims for its adoption, but must compete on an equal footing with established methods, the basis of comparison being cost of installation and operation. When the inventor, who undertakes to design and construct a compressed air street motor, is able to convince street railroad capitalists, by an actual demonstration, that his system can be installed and successfully operated at a reduced cost per car run, then, and then only, will compressed air be used in this service. The history of the various compressed air motors which have been exploited from time to time is a chequered one, but the fact that compressed air yet lacks a thorough demonstration is due either to incompetent efforts, or to causes entirely foreign and beyond the control of those interested. Compressed air locomotives for mine service, *Cassier's Magazine* says, are used extensively, and, at their present state of development, run anywhere from one to three miles with one charge of air, hauling loads which may vary from 50 to 100 tons, and surmounting any gradients that steam locomotives can travel with economy.

NOTES AND MEMORANDA.

A new apparatus for electrolysis was recently described to the Paris Academy of Sciences by M. D. Tommasi. In the apparatus described the advantages claimed are the suppression of polarisation, that the deposited metal is removed from the oxidising action of the bath, and that the electrical resistance of the bath is considerably reduced.

Another powerful illustration of the constant tendency of the mountains to take a lower seat was afforded on the 30th ult., when the village of Vienholz, near Brienz, in the Bernese Oberland, was partly destroyed by subsidence and landslips, caused by natural springs. The roads were destroyed, and railway communication has been interrupted.

Mr. A. E. Hunt, in the March number of the *Aluminium World*, estimates the minimum cost of electrical horse-power in the United States at £4—5 per annum, using water power, or £12—20 by the aid of coal. In their paper on "The Manufacture of Calcium Carbide," in the *Journal* of the American Chemical Society, Messrs. Morehead and De Chalmot mention that the water in the race-ways is offered to the Willson Aluminium Company at a rate of 25s. per horse-power per annum.

A series of comparative tests of Portland cement made by American, English, German, Belgian, and Danish manufacturers, published by *Engineering News*, shows that no nation has a monopoly of the manufacture of good Portland cement; on the contrary, the reputable brands of cement appear to be of about the same quality in one country as in another. This is after all what should be expected. Portland cement is made from certain well-known constituents, and if those are combined in proper proportions and the process of manufacture is correctly conducted, the product should be about the same, no matter where the manufacture is carried on. There has been, and still is, a large amount of "superstition" concerning cement among engineers; and we even now hear it said that this or that or the other country is the only one that can produce "genuine" Portland cement. The diagrams published by our contemporary appear to show how little foundation there is for such statement; and "the fallacy of the still too common impression that American Portland cements are inferior to that of foreign countries."

To avoid the dangers which result from the use of kerosene (commonly in this country inaccurately called paraffin, for it is a mixture of naphtha and heavy oil) and to prevent some of the lamp accidents, it has been proposed to exclude cheap foreign lamps and alter the oil flash-point. Instead of this the *Chemical Trades Journal* says:—"Instead of the 'simple exclusion of the lamp,' exclude neither lamp nor oil; but, simpler far, inspect them both. Send back the really defective lamps and take in the naphtha as naphtha and the petroleum as petroleum. Make the legal standard the same as the trade. Either define the percentage of naphtha that petroleum is to contain or take the existing written testimony of experts and class only as petroleum the product distilling from crude oil between 150 deg. and 300 deg. Cent. For convenience sake, check the percentage of naphtha by the Abel flash-point, though this will not prevent completely the substitution of prepared oils. It will, however, prevent the loss of 300 out of the 365 lives a year that are lost by the use of the 'stuff' that the Government practically sanctions as safe for use as burning oil. That is the spirit of all we want, or that public safety demands. This is all we want, and this is all the oil companies do not want."

An electric process of converting emery into corundum by means of the alternate current arc has recently been patented, says the *Trade Journal Review*. As heat, and not decomposition, is aimed at, continuous currents would be unsuitable. This furnace is made of firebricks and stands on two bridges; the hollow underneath serves as receptacle for the fused mass, there being a small hole in the bottom of the furnace. This hole is covered with a glass plate. The electrodes—carbon rods—are approached to within 1in. to 2in., the space between being packed with lumps of carbon. The emery, the finest dust, of little use otherwise, is mixed with powdered coal, the amount depending upon the iron oxide in the emery; for 25 per cent. of oxide 5 per cent. of carbon is reckoned. The coal is soon burned by the oxygen of the iron oxide and the arc forms. The inner mass begins to melt, the glass plate gives way, and a stream of fused corundum flows out. The hard outer crust is then broken with iron rods, and new material thus fed to the arc. This addition stops the flow, which starts again after ten or fifteen minutes. The baseplate is strewn with fine emery powder to protect it from the intense heat of the fused mass. The resulting corundum is almost free of water, of which the emery contains about 5 per cent.

In their investigations into the possibility of transforming carbon into graphite, MM. Girard and Street have devised several modifications of the electric furnace. These, together with the results of their experiments, form the subject of a paper in *L'Eclairage Electrique*, iv., page 454, and there is an abstract of the paper in the "Proceedings" of the Institute of Civil Engineers, cxxiii., page 78. The furnace consists of the usual block of refractory material, through which passes vertically into an inner cavity the rod of carbon to be converted into graphite, and another rod to meet it at right angles. At the junction, of course, an arc is maintained. The first carbon passes into the furnace at a speed which depends upon the temperature of the furnace. In the case of carbons for arc lighting, the rod is also given a rotary movement as well as a translatory movement. The effect is stated to be as follows:—The effect of the arc is to leave a spiral trace on the carbon to be converted, this tracing indicating the path of the conversion into graphite. Obviously, the whole surface of the carbon can thus be graphitised. The *Electrical Review* says the result upon the physical properties of the carbon is, that both the conductivity for heat and that for electricity is increased fourfold, whilst the density is also enhanced—these being advantages by no means to be despised.

Various substances and mixtures have been proposed for replacing gutta-percha as an insulating material for cables, but although many of them are effectual in other particulars, none have, so far, rivalled it in point of durability under prolonged exposure to the action of sea-water. Paraffin alone is too brittle, but the plastic products of the incorporation of ozokerite with small quantities of caoutchouc form a medium which in insulating power and durability almost rival the latter substance in its pure state. The degree of insulation attained by Henly's cable, which is coated externally with ozokerite, is 5000 megohms per knot. Nigrite, prepared by kneading together caoutchouc and the residue from the distillation of ozokerite, is far superior, both mechanically and as an insulator, to gutta-percha, and is less susceptible to heat than caoutchouc. The composition, consisting of a mixture of resin and heavy resin oils, used for the Brooks cable has a high insulating power, several samples having indicated regularly 19,000 megohms per mile. Wray's composition, made from caoutchouc, silica, powdered alum, and gutta-percha, is largely used in climates too hot for gutta-percha by itself, but is quickly attacked by sea-water. Latterly, attention has been directed to balata as a substitute for caoutchouc. This gum is obtained by tapping the balata tree, of which there are large forests in British Guiana and other parts of South America. There are two varieties—the red or "bullet tree," and the white, or true balata; they grow to a height of 90ft. to 100ft., and can yield about 2½ lb. of gum in a year without overtaxing their strength. The liquid gum soon hardens on the surface, which is then removed, and this continues till the whole has solidified. For insulating purposes balata gum is, says the *Journal* Society Chemical Industry, inferior to caoutchouc, but it makes a good waterproofing material, and is highly suitable for driving-belts.

MISCELLANEA.

The armoured cruiser Terrible is to commence her preliminary trials at Greenock on the 14th June.

The third Congress of Chambers of Commerce of the Empire takes place June 8th to 13th, in the hall of the Grocers' Company.

It is proposed to import crude petroleum on a large scale into this country and to refine it here as it is done in some other countries. The oil in this case would have to be Galician or Russian, and it would not pay so long as no duty is enforced on imported refined oil.

The ninth Milling Congress will be held in Paris on the 7th, 8th, and 9th of July, at the Champs de Mars, in the Central Dome and Long Gallery. The exhibition of milling, bakery, and agriculture will be opened from the 6th to the 16th of July. The secretary is M. L. Corun, 6, Place du Louvre, Paris.

An Exhibition of Manufactures, Appliances, and Inventions for the Saving of Life is to be held at the Central Hall, Holborn, from July 9th to 18th next, in aid of the Guy's Hospital Fund. Demonstrations by members of the St. John's Ambulance and the Life-Saving Society will be given, and many other attractions will be offered.

In a recent book on "Mechanism in Men-of-War," by R. C. Oldknow, R.N., the author considers it probable that steel will in future be superseded by aluminium; slightly alloyed, it is the ideal metal for all castings where great strength is not required. *Aluminium* is told also that the German Government has decided, after the teachings of the Chino-Japanese war, that no more wooden furniture is to be carried, but aluminium ware is to be substituted.

The Isle of Man Steam Packet Company have placed with the Fairfield Shipbuilding Company, of Govan, an order for a new paddle steamer which, for size and speed, is intended to eclipse any vessel of the description afloat. The ship is to be 350ft. long and 42ft. wide, and will have engines of 10,000-horse power. She will have four decks, the upper one of which will be for promenade purposes. The accommodation will be for 2000 passengers, and the cabins and saloons are to be luxuriously fitted. The steamer will be placed on the Liverpool and Douglas station for the carriage of the mails and passengers early next summer.

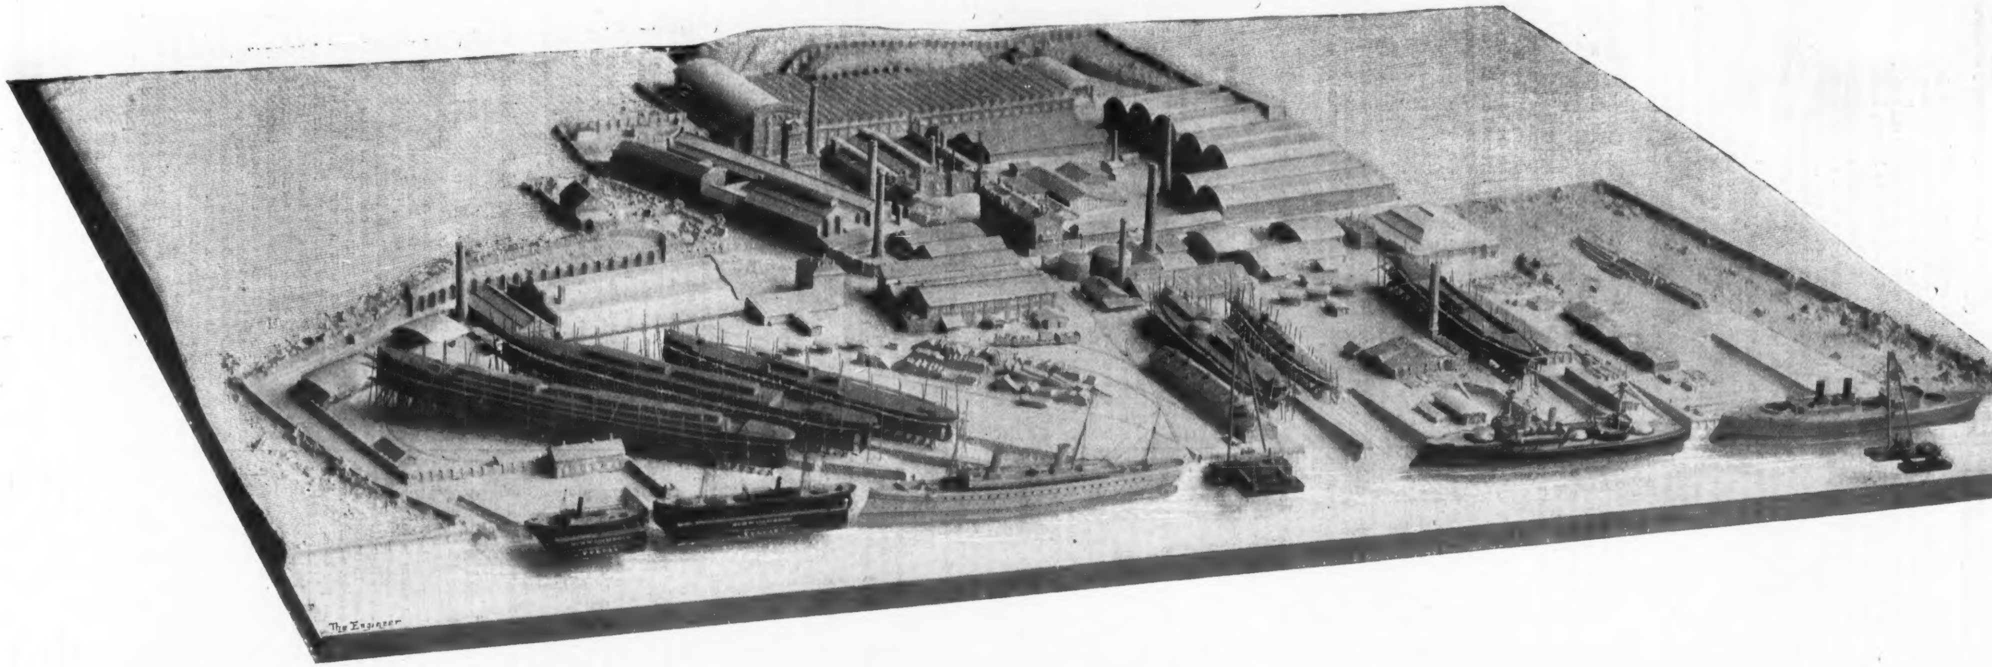
It was reported on the 30th ult. that two distinct earthquake shocks were experienced, one in the south-west of Scotland and the other in the west of England. At a quarter to five o'clock an earthquake shock occurred in Dumfriesshire, the noise resembling a distant peal of thunder. Furniture and crockery were agitated by the shock, which lasted a few seconds, but was not attended by any damage of consequence. The seismic disturbance travelled in a north-easterly direction, the same line as the shock experienced a few days previously. Shortly before seven o'clock a slight shock of earthquake was felt in West Cornwall. The men on their way to work at the Camborne mines noticed the vibrations distinctly.

Undeterred, apparently, by the movement in Congress to have steam yachts which are built outside the States debarred from flying the Stars and Stripes, and from sharing in the privileges and exemptions which that distinction confers, Mr. Robert Goelet, of New York, brother of Mr. Ogden Goelet, for whom a similar yacht is at present well under way in the yard of Messrs. J. and G. Thomson, Clydebank, has just commissioned that firm to build him a twin-screw steam yacht of 1750 tons yacht measurement. Like his brother's vessel, the later boat will be most sumptuously fitted, and will be propelled by triple-expansion engines, capable of giving a speed of 18 knots. Mr. R. Goelet at present owns the steam yacht Beatrice, of Boston build, so that from all points of view the new order is a compliment to British designers and builders. In this connection, however, it may be added that a splendid new twin-screw steam yacht has just been launched from an American yard, the designer of which is Mr. J. Beaver Webb, an Englishman who married an American lady, and is now a resident of New York City. The new vessel, named the Sovereign, has been built by the Erie Basin Shipbuilding Company, New York, and is 260ft. length over all, 212ft. on water line, 28½ft. beam, and 18½ft. draught. The owner is Mr. C. D. Borden, of the New York Yacht Club.

The bursting of a fly-wheel is almost unheard of in England, notwithstanding the high-speed engines we now have running, yet in the United States the fly-wheel "casualties that have become a matter of weekly report," as *Cassier's Magazine* says, "are evidence of slow evolution in providing for known wants." In England we have many thousands of high-speed cast iron fly-wheels and very large wheels up to 60 tons weight running with very high periphery speed, and they all run safely, and yet in the States they say, "The sudden advent of electrical apparatus and its high speeds found people making fly-wheels of cast iron, with a narrow factor of safety, or, indeed, no factor of safety at all, if we consider the impossibility of detecting inherent strains and imperfections in this material. No one can know the value of material moulded into form at a temperature of 2000 degrees and then cooled down to a fortieth of this temperature, nor can they judge internal structure by surface indications. The fact is that cast iron is not suitable material for fly-wheels that are to be driven at high speed, nor is it necessary to make them of this material. There is not even the claim of cheapness in their favour, if the methods of making such wheels of wrought iron and steel were once worked out. Twenty years ago a Scotch firm, who had to make a large fly-wheel for a spinning mill, riveted up a box rim, made from rolled plates, and filled it with cemented masonry or 'grout,' and did a very sensible thing."

The brick-making industry at Peterborough seems to have made great strides in the last few years. On Saturday a large company, including many strangers, were present at the Great Northern Hotel, where Messrs. Fox and Vergette offered for sale an estate of 88 acres, situate in the midst of the Fletton and Yaxley brickfield. From a small concern, giving employment to perhaps twenty hands, the brickyards have developed into a great centre of activity, in which there are sixteen large Hoffman kilns, and fully as many Dutch, Suffolk, and other kilns at work, turning out every year bricks enough to build a small town, and employing hundreds of men; one railway alone carrying about a quarter of a million tons a year. The bed of workable clay extends along the line of the Great Northern Railway about two miles, and the brick-makers of the district have bought up the greater part of the land having a railway frontage. The pressed bricks are general favourites in the trade, because of their cheapness, soundness, evenness of size and quality, their sharp and well-defined arris, and their suitability for heavy work. They have, it is said, when tested, withstood a pressure of nearly 200 tons per square foot. It has been claimed for them that "they are cheaper and better than stocks, taking less labour, less mortar, and at the same time making stronger work, with greater resistance to fire and water." The clay is of a dry nature, and is clean and easily worked. At a recent meeting of the Society of Architects, Mr. Ellis Marshall, hon. sec., read a paper on "Bricks and Brickmaking," in which he referred to the Peterborough bricks, and said, "The clay of Peterborough is of a remarkable nature. It contains a large amount of shale oil, which assists the bricks in burning in somewhat similar way as the breeze assists the stock brick. The bricks are made either plastic or semiplastic." In the course of recent sinkings another substance differing from the clay was found in large quantity, and is supposed to be applicable to various purpose

THE VULCAN WORKS, STETTIN



THE VULCAN WORKS, STETTIN.

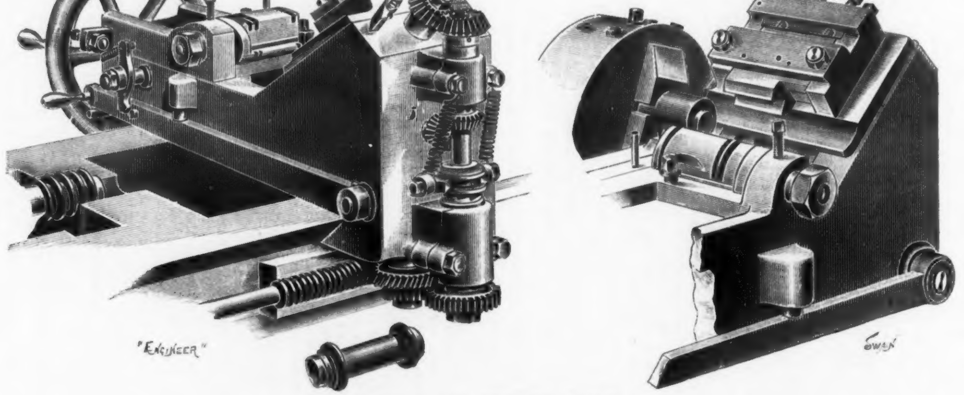
The Vulcan Works near Stettin, to be visited by the Institution of Naval Architects this year, have a brisk and interesting record of shipbuilding and engine manufacture since their commencement. We engrave a plan of the works and building slips, from photograph taken from a very fine model in the possession of the company.

This company—the Vulcan Engineering Company of Stettin—was founded in the year 1857. The creation of the works originated so far back as the year 1851, in which Messrs. Früchtenicht and Brock erected, in a small space, a wharf for iron ships, with a machine shop at the same spot. The original plan had perhaps one-fifth of its present extent, which now embraces twenty-five acres.

Almost simultaneously with the establishment of the new company shipbuilding was inaugurated, and the manufacture of locomotives was also commenced; so that, by the beginning of the year 1859, the first locomotive actually constructed at the works had been already delivered. In 1866 the first small war vessels built by the company were completed, and in 1869 the first set of large marine engines for the armoured frigate Hansa. The first order for a large armoured ship—the Preussen, for the German Navy—was given to the Vulcan Company in the same year. Up to the present date 235 ships and more than 1500 locomotives have been built by the Vulcan Company for home and abroad. These 235 ships included, besides various small war vessels and merchant vessels of all classes, seventeen great battleships and cruisers for the German Navy, also six large war vessels for the Chinese Navy, and a considerable number of torpedo boats. Amongst the numerous vessels built for the merchant navy, many of the largest fast steamers and cargo boats for the Transatlantic trade may be mentioned. At this moment the following ships are in course of construction:—One twin-screw fast steamer of 20,000 tons displacement, and 28,000 indicated horse-power; two twin-screw cargo and passenger steamers of 17,600 tons displacement, and 7000 indicated horse-power; two cruisers for the Imperial German Navy, each of 5600 tons displacement.

With the exception of large rolled material, heavy shafting, and other heavy forgings, all parts of ships and propelling machinery can be completed by the Vulcan Company in its own workshops.

The average number of workmen employed amounts to about 4500. The value of the works is now 16,500,000 marks, whilst the subscribed capital of the company only amounts to 8,000,000 marks. A mark is worth nearly a shilling. By the courtesy of the company further photographs of the works have reached us, which will appear in our pages in due course.



BICYCLE HUB FORMING LATHE

BICYCLE HUB FORMING LATHE.

This is a very substantial tool, having the headstock cast solid with bed, the spindle being driven by a two-step cone for 5in. belts and has friction back gear, which is so proportioned that the cone gives the correct boring speed, while by throwing in the back gear the speed is right for forming. The spindle has a 2in. hole, and can be supplied with a stockfeeding mechanism if desired. The turret is of solid design, gibbed directly to bed, and is fed by a screw under the turret, as near the line of strain as possible; two changes of power feed are provided. The hand motion is operated by a pilot wheel having long handles.

The hub-forming slide, of which we show details, is an interesting feature, and is made in box form, gibbed to the bed so as to be rigidly held in position. But one forming cutter is used, of the round type, as can be seen in the illustration, this being easy to set, and held in exact alignment with the spindle.

The back slide moves in dovetailed ways at an angle of 45 deg. from the plane of the cutter slides; the two slides being geared together so as to feed exactly together as the stock is removed, thus supporting the hub with the greatest nicety against the action of the cutter. The back jaws are made of high-grade tool steel, hardened, ground true, and polished. They are held in the slide by a steel clamp and bolts, and both upper and lower jaws are independently adjustable, by means of set screws. A pump is furnished with each machine, which is driven at constant speed by separate pulleys on the countershaft. This supplies an abundance of oil to a manifold oiling device—not shown in cuts—and which is so arranged as to oil both the cutter and the back jaws independently. Power feed for the cutter and back slide is furnished, operated by worm and gearing from the rear feed shaft, which also feeds the turret. An automatic stop mechanism is also provided, which stops the feed at any predetermined point.

This method of forming produces very smooth work, as it holds the stock very steadily against all tendency to spring away from the cut, and at the same time is rapid in action, because the hubs can also be bored while the forming cutter is at work, and then, when the forming operation is completed, the lathe may be run at the cone speed to finish the drilling. A cutting-off tool with adjustable blade is pivoted on the cutter slide, which cuts down the stock after the forming, so that the drill itself removes the hub from the bar.

They are made by the Niles Tool Works, Hamilton, Ohio.—*Machinery.*

EXPRESS ENGINE, MIDLAND RAILWAY.

On December 13th, 1895, we published as a supplement an external elevation of an express engine on the Midland Railway. Through the courtesy of Mr. Johnson we are now enabled to publish a working drawing of the same engine, which supplies information for which we have been asked by many of our readers. In our impression for January 31st, will be found cross sections of the same engine.

THE TELAUTOGRAPH

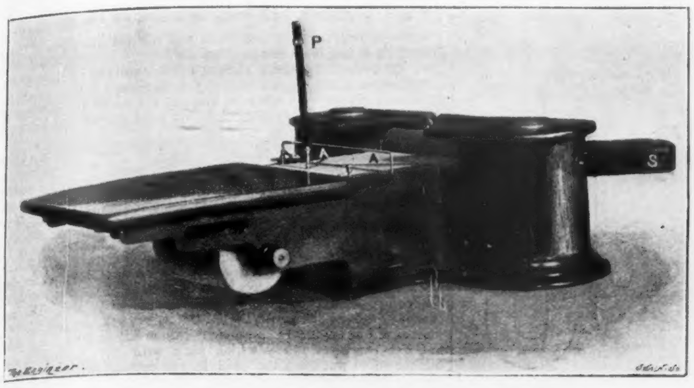


Fig. 1—TRANSMITTER—EXTERNAL VIEW

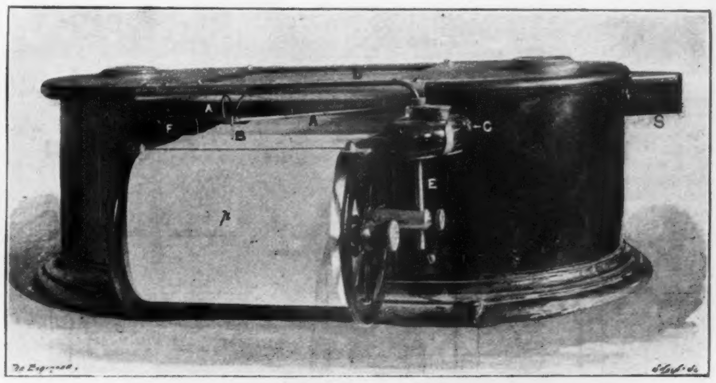

Fig. 2—RECEIVER—EXTERNAL VIEW

PROFESSOR ELISHA GRAY'S TELAUTOGRAPH.

In the year 1891 the new instrument to which the inventor, Professor Elisha Gray, of Lake County, Illinois, U.S.A., has given the name of the Telautograph, was exhibited in the Chicago Exhibition, and was referred to by our Special Commissioner. At that time, however, we were not able to describe the details of the apparatus, the chief reason being that changes and improvements were still being made which were not protected by patents. In June, 1894, the instruments were exhibited at the conversazione of the Royal Society, and recently the actual work of supplying the apparatus in Great Britain has been undertaken by the Telautograph Company, Limited, of 97, Gresham-street, E.C., to whom we are indebted for the photographs used for illustration, and also for the details of the construction o the instruments.

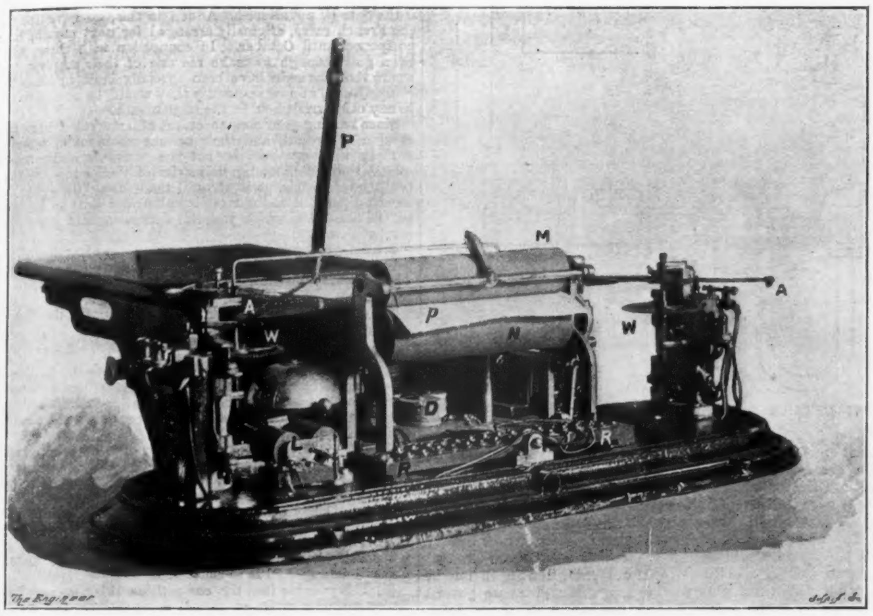

Fig. 3—TRANSMITTER WITH COVER REMOVED

The apparatus we examined consisted of two stations, each provided with a transmitter and receiver, these being separate instruments. The line consisted of four wires, and its resistance was about 25 ohms, but it is merely a question of different winding of the electro-magnets to be able to transmit the messages to different distances, and we understand that the apparatus has given very satisfactory results when used upon the London-Paris telephone line. Since its appearance at Chicago Exhibition the mechanism of the instrument has been much improved and simplified, and we are told that further improvements are in progress which will combine transmitter and receiver into one single instrument, and enable connection to be made between two stations by means of two wires instead of four. These machines have, however, not yet arrived in this country, and our description, therefore, refers to the type now being put upon the market, and let out on hire here.

In Figs. 1 and 2 we give views of the exterior of the transmitter and receiver respectively. Upon the transmitter an ordinary lead pencil P is used, near the point of which light rods A A are fastened at right angles to each other. These rods are connected to the instrument, and following the motions of the pencil regulate the current impulses which control the receiving pen at the distant station. The writing is done upon ordinary paper *p*, 5in. wide, conveniently arranged upon a roll attached to the instrument, and passing over the table T. A lever to the left is so moved by hand as to shift the paper forward mechanically at the transmitter and electrically at the receiver.

At the receiver the pen B is a capillary glass tube placed at the junction of two aluminium arms A A. This glass pen is supplied with ink, which flows from a reservoir C, supported on a bracket E, through a small rubber tube D, Fig. 4, connected to the joint of the arms at B. The arms are supported by the horizontal rod F. The electrical impulses coming over the wire move the pen of the receiver simultaneously with the movements of the pencil in the hand of the sender. As the pen passes over the paper an ink tracing is left, which is always a fac-simile of the writing done by the sender, whether in the formation of letters, words, figures, signs, or sketches.

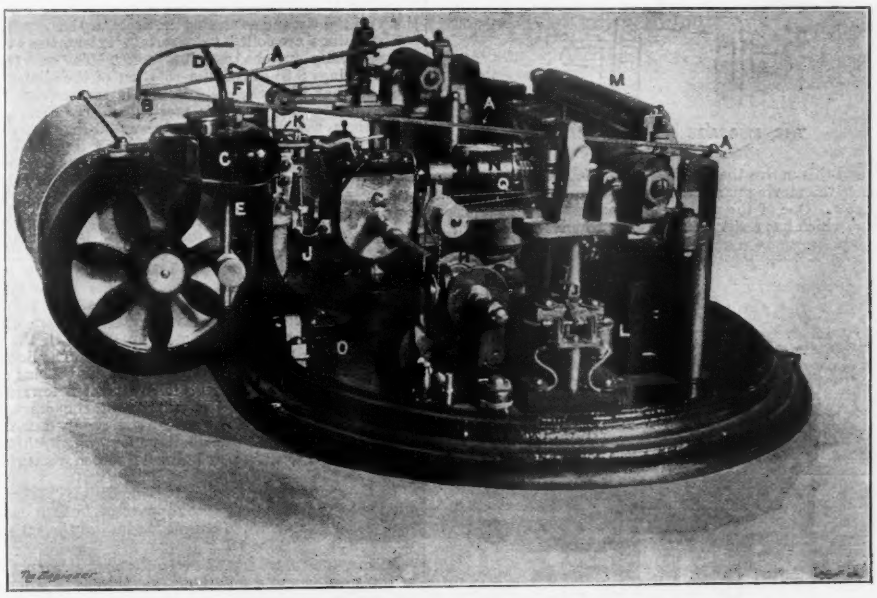

Fig. 4—RECEIVER WITH COVER REMOVED

On lifting the covers of the instruments the mechanism is seen to be somewhat complicated, and we shall now endeavour to describe the chief features as clearly as possible. Figs. 3 and 4 are taken from photographs of the transmitter and receiver respectively, with the covers removed.

The mechanism may be divided into four parts as follows:—Pen-lifting gear, paper-shifting gear, pen-directing gear, and prime mover. The power which works the whole apparatus is obtained from two batteries of small lithanode secondary cells, each battery consisting of six cells, so that 12 volts are obtained from each battery, and they can be put in series to obtain 24 volts.

Pen-lifting gear.—The action of this gear is shown diagrammatically in Fig. 5. The pencil P is not exerting any pressure upon the platform B, and therefore the lever C is held against the top contact D by the spring E. Current flows in from the battery to L^1, and as the resistance coil G^1 is short circuited, it passes direct to the bobbin H^1 of the electro-magnet, at the same time current from L passes through the resistance coil G, and energises the magnet pole H; the pole H^1 is therefore now the stronger, and attracts the ends of the lever J, free to rock upon the fulcrum K, and the pen support F holds the pen pipe M out of contact, with the paper at the receiver. So soon as the pencil presses the platen B in the act of writing, the lever C descends on to the bottom contact D^1, and the pole H at the receiver becomes stronger than the pole H^1 the lever J rocks over, the pen support F descends and the bent end of the pen pipe M touches the paper, the ink flows, and writing begins.

The same electro-magnet H H^1 is used for the paper shifter in the following manner. A stronger current than that used for the pen gear is sent through both the bobbins H and H^1, and as the fulcrum K is free to move vertically, and is only controlled by the spring N, the result is that the armature J is attracted to both poles at once, and the centre pin O makes contact with O^1 and a current is passed to the paper shifter P S, which will be described in detail afterwards.

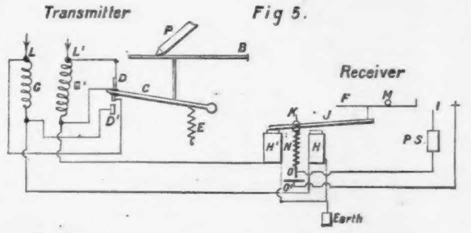

Fig 5.

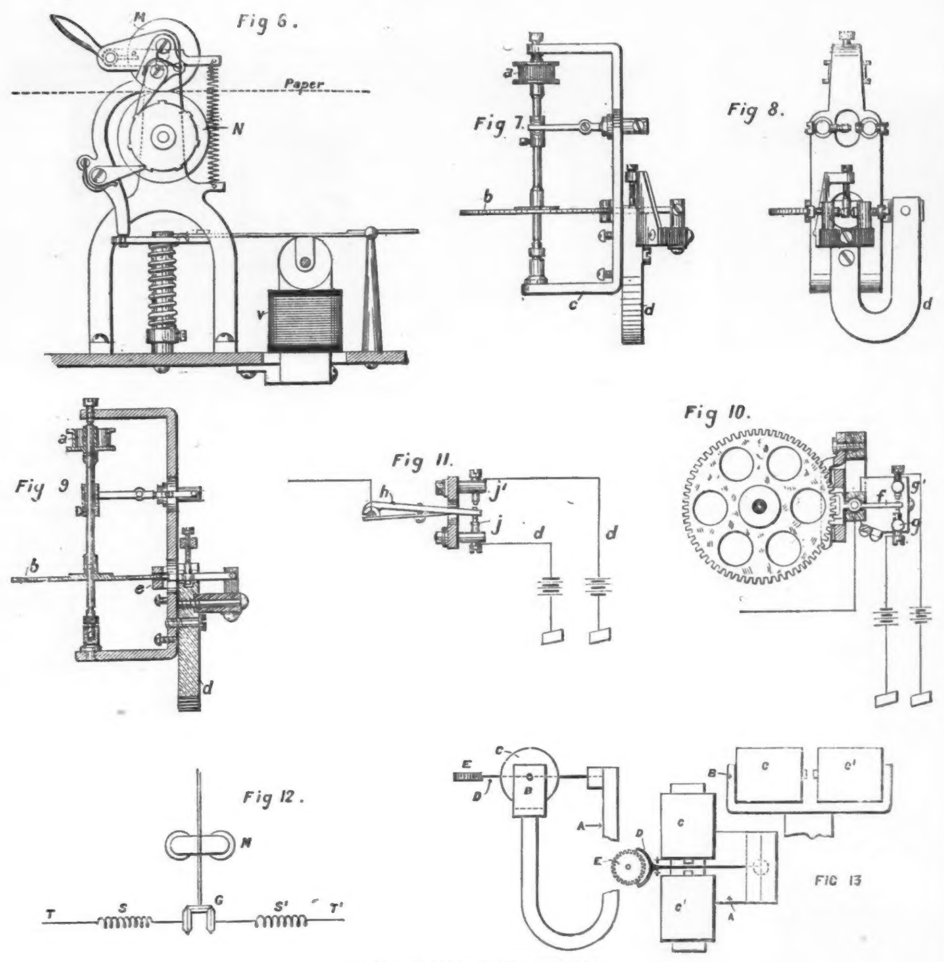
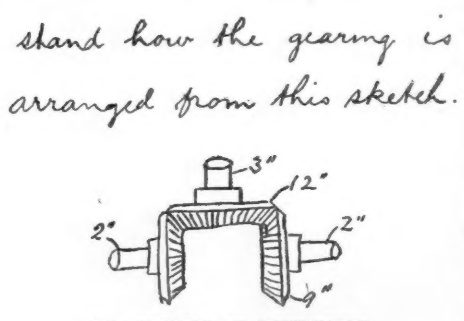
Paper-shifting gear.—At the transmitter the roll of paper is placed inside the instrument, and the end *p* is carried out through a slit over a guide roller, then over the platen upon which the pencil works, and thence between a pair of rollers M and N. The paper is moved forward mechanically at the transmitter, the used portion being rolled upon the roller at the back of the machine. The action of moving the paper at the transmitter causes the electro-magnet H H^1, Fig. 5, to be energised, as already explained, and the mechanism shown in Fig. 6 is actuated at the receiver. It will be seen that the paper passes off the roll inside the apparatus as already described, and as soon as current is sent through the electro-magnet V the paper is gripped between the rollers M and N, and is pulled forward a distance corresponding to that by which it is moved at the transmitter. We are now prepared to deal with the actual writing mechanism.

Writing mechanism.—As we previously stated, the pencil P on the transmitter has attached to it two light rods A at right angles to one another, and both moving in the same



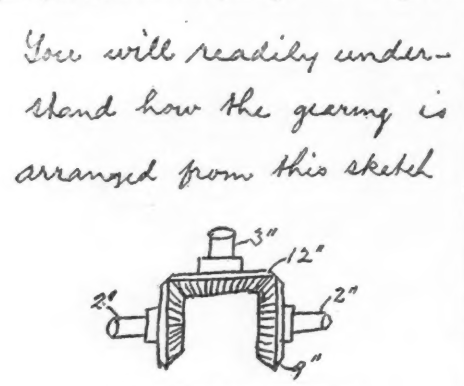
THE TELAUTOGRAPH—DETAILS

plane. Each rod acts in a similar way to the bow of a fiddle drill, for it has a light cord attached to it at two points, and the slack of this cord is wound several times round a small pulley, so giving motion to the part of the apparatus called the interrupter W, Fig. 3; each arm actuates one interrupter, and these two interrupters allow current impulses to pass into the line wires. One of the interrupters is shown in Figs. 7 to 11. Here *a* is the pulley actuated by the fiddle bow, and this moves the toothed wheel *b*. A light frame *c* supports the moving parts, and to it is fixed the horseshoe magnet *d*. One of the poles of this magnet has an extension piece *e*, which has a slit in it, through which the edge of the toothed wheel passes. The edge is, therefore, of north polarity, let us say, while the south pole of the magnet is provided with a rocking tongue *f*, working between the contact screws *g g*. The teeth are so spaced with relation to the forked end of the tongue *f* that one prong of the fork is opposite a space, while the other is opposite a tooth.



You will readily understand how the gearing is arranged from this sketch.

THE MESSAGE AS TRANSMITTED



You will readily understand how the gearing is arranged from this sketch

THE MESSAGE AS RECEIVED

In Fig. 10 it will be seen that the lower prong is attracted to the tooth of the wheel and closes the magnetic circuit, or at least causes the lines of force from tooth to prong to be much greater in number than for the upper prong; the result is that the tongue *f* closes the bottom contact *g*, and current goes to line. If the wheel *b* rotates still further, the opposite action will take place, and the top contact g^1 will be closed. Seen in plan in Fig. 11 the rocking lever *h* lightly grips the spindle, and therefore changes contact on the two terminals $j\,j^1$. These interrupted currents, flowing in one or the other direction, pass to the receiver, and there govern the direction of the pen. Before dealing with these, however, it will be necessary to examine another part of the receiver.

Prime motor.—The interrupted currents on the line play merely the same part as the pendulum of a clock—that is to say, they work the escapement, but the power to actuate the pen of the receiver is provided by an electro-motor N, Fig. 4, arranged as shown in Fig. 12. Current is obtained from the two secondary batteries in series, giving 24 volts, and the motor shaft drives the equalising bevel gear G—also marked G in Fig. 4—and thence the spiral springs S and S^1 coiling them up tightly, and so storing the necessary energy. As soon as the springs are coiled to a certain extent the current is automatically switched off the motor. The energy of the coiled springs S S^1 causes the rotation of the shafts T T^1 as soon as they are released. Power is transmitted through T and T^1 to the reversing mechanism H, Fig. 4, which determines the direction of motion. From the reversing mechanism power is transmitted through light silk cords to the escapement shaft, these cords being wound several times round their respective pulleys. These shafts are, therefore, always tending to turn in one or other direction, but the amount of movement is controlled by the escapement.

Escapement.—There are two similar escapements, one for each arm of the pen, and one is illustrated in Fig. 13; *a* is a horseshoe magnet carrying a bracket *b*, to which are fixed two bobbins *c* and c^1. To the other pole of the magnet is hinged a kind of anchor movement *d*, which acts as the escapement. Holding or releasing the escapement wheel, which has teeth corresponding in number with the teeth of the interrupter wheels, in the transmitter. The line current from the interrupter flowing through the bobbins *c* and c^1, causes the escapement pawl *d* to be attracted toward one or the other according to the polarity of the current—thus releasing the wheel *e*. The wheel *e* is rigidly attached to a spindle which carries the small pulley, which, through the fiddle-bow gear, drives and directs the movements of the pen.

In the space at our disposal it is impossible to trace out the whole of the connections of the apparatus, but our description will, we believe, suffice to give a clear idea of the action of the instrument.

In conclusion, we reproduce in the next column a message as transmitted and received, and we think this will appeal to our readers, as it shows the practical use to which the apparatus may be put by engineers. The originals are about twice as large. It will be seen that the reproduction is practically a *fac simile*.

We are informed that the Telautograph Company has made arrangements with the National Telephone Company, and the latter company will permit its lines to be used for the new instruments, which can be hired at yearly rentals as telephones are now obtained.

LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

"THE ENGINEER" HORSELESS CARRIAGE COMPETITION.

SIR,—In your issue of last week you ask for the views of those interested in the horseless carriage industry, regarding the date of THE ENGINEER Horseless Carriage Competition. I beg leave, therefore, to offer you not only my own view, but the unanimous opinion of those who come to consult me as to the position of affairs generally concerning common road mechanical vehicular propulsion.

My own great desire in taking upon my shoulders to a large extent the responsibility of an exhibition, the primary object of which was to bring to the notice of the British public a matter which I think, with you, in the very near future, will constitute an industry of great national importance, was that I might be of some service to the engineers and carriage builders of my own country, and to prevent as much as possible the importation of ill-designed, badly constructed, and unsatisfactory foreign built self-propelling carriages. My efforts will be very small in comparison with the good work you have initiated, provided the time at which the competition is to take place be an apposite one. The concensus of opinion, however, is that October is considerably too soon.

Even if our engineers had a clear course before them, they could not get carriages ready which they with any degree of confidence could put upon the road in competition with our friends on the other side of the Channel, who have been building them with practically no restriction or hindrance for many years. The course, however, is by no means clear, for legislative restrictions have not yet been removed, and therefore it is impossible to say, at this date, what will, or will not, be allowed upon our highways. Under these circumstances, engineers could hardly be expected to construct carriages which might be subjected to considerable modification on the passing of the proposed new Act.

I am sure, Sir, you will appreciate the fact that English engineers are perfectly willing to enter the lists with any country, and if the prizes, munificently offered by THE ENGINEER, are to be taken to foreign shores, they will accept their beating in true British style. All the same, they would like to have a fair representation at the competitions, which they cannot possibly do if the date be not altered. Added to this, we have the fact that the French races, originally arranged for next month, have been postponed until October. In connection with these, they have been good enough to make me one of their umpires, and I am aware that carriages have been specially built by them for these competitions, and consequently they would be unable to take part in any other trials held in the same month.

Since reading your announcement of last week I have taken the opinion of several, and their unanimous opinion, which accords entirely with my own, is that you would be doing considerable service to the engineering industries of this country if you would postpone the trials, at least until next May. June has been the month suggested as the most suitable, and it is to be hoped will be the one upon which you will decide to hold your interesting competitions.

I trust you may see your way to this postponement, and that your trials may be the cause of putting upon the road vehicles of which we may have reason to be proud.

ALF. R. SENNETT,
Hon. Executive Commissioner for the Exhibition.
Crystal Palace, S.E., May 27th.

SIR,—With reference to your inquiry as to the feeling of those proposing to enter auto-cars for your competition in October, with regard to the postponement of the date for the competition to the following spring, I shall be glad to mention some considerations which occur to me.

(1) Intending competitors may have already taken measures to be in readiness for the competition in October, the expense of which might have been avoided had they known of the possibility of an extension of time.

(2) Competitors may have arranged their business plans and expenditure with a view to availing themselves of the splendid advertisement which your report will give them, and if this were postponed for six months their outlays would be locked up and plans disarranged so as to cause loss.

(3) It is possible that the competition this year may become the forerunner of a series of annual competitions, and its postponement would cause the loss of a year.

Might I suggest that instead of postponing the date of the competition until next spring, you might with advantage to competitors postpone the date of entry from the last day of July to the last day of August, and the competitions to the month of November.

WM. ROSE SMITH, M. Inst. C.E.
3, Laurence Pountney-hill, E.C., May 28th.

P.S.—Further inquiry and consideration since writing above lead me to think that the proposal to postpone the competition till next summer is the more advantageous. Please to add this postscript to my letter of the 28th May.—W. R. S.
June 2nd.

[In response to the questions we have asked in our last two impressions, we have received a number of letters from all parts of the country advocating postponement in the best interests of the horseless carriage. Mr. Sennett's letter may be taken as a type of the rest. Mr. Smith, whose letter we print, held opposite views, and it will be seen from his postscript that on further inquiry he has changed his mind. We have only one letter to the contrary, giving as a reason the probability that the writer would be the only competitor with a heavy oil carriage if the trials were not postponed.—ED. E.]

THE LIQUEFACTION OF GASES.

SIR,—I am disposed to agree with "Zero" as to the futility of further correspondence. His methods are such as to render any real discussion almost impossible. Facts quoted that make against his views he for the most part ignores; if he does notice them it is only to commit the logical fault of *ignoratio elenchi*. At other times he fathers on me statements I have never made. For instance, he accuses me of pointing to the compressing pump in connection with external work. Will he kindly tell me on what page of THE ENGINEER I did anything of the sort? I did say, in opposition to his view, that the compressed gas escaping from the nozzle does external work, at least against the atmosphere. If he attempted to meet that proposition by talking about work in the pump, he merely evaded the point at issue, and should blame himself, not me, for irrelevancy.

Why I insist on the need for the Joule effect is simply because the cold produced by "mere expansion" will give no final cooling effect in the Hampson machine. A thermometer placed in the stream of gas just as it leaves the orifice will indicate a reduction of temperature, but if placed a few inches along the tube it will stand much higher, because the energy of mechanical motion of the issuing gas is reconverted into sensible heat, which neutralises the cold produced by expansion. If "Zero" can meet this statement fairly and squarely, and successfully refute it, there might be some hope for his theory, but unless he can do that his theory plainly cannot stand. Nor can his fundamental erroneous assertion that the "energy in a gas is a function of its temperature and of nothing else." The latter statement would be true only of a 'perfect" gas, which might indeed be passed through Hampson's machine for centuries without liquefaction of a single drop.

The suggestion that Kelvin's arrangement has nothing in common with Hampson's scarcely deserves notice. Obviously, in that in both compressed gas is expanded through a narrow orifice situated in a long tube, they are essentially identical.

"J." must surely know that the existence of the Joule effect does not depend only on a few doubtful experiments, but is a necessary consequence of known laws of gases and of received theory. Perhaps he regards Boyle's law as rigidly accurate, and has not reflected that the deviations of gases from that law are precisely parallel to their behaviour in respect to the Joule effect. I do not know whether the figures I gave are the results of calculation or of direct experiment. But they are Lord Kelvin's, and as such carry more weight, with me at least, than "J.'s" *ipse dixit*, which I imagine is founded neither on experiment nor on calculation.

"Zero," being a law unto himself, will probably have the same indifference for authorities as he has for ascertained fact. It may, however, be worth mentioning that Professor Ohnes, of Leyden, the possessor of one of the few cryogenic laboratories in the world, in a recently issued paper, takes it for granted that a machine like Dewar's or Hampson's depends on the Joule effect. Dewar, too, in his last lectures—which I heard but could not have read, seeing that they are not printed—did the same, and exhibited elaborate tables based on the same supposition.

With regard to the questions asked by your other correspondent, I can tell him that the temperature of the exhaust gas from the Hampson apparatus is distinctly cooler than that of the room. But on entering the compressor it must be simply at the temperature of the surrounding atmosphere, for at Brin's works, at least, no attempt was made at thermal protection of the pipe leading from the machine to the pump. Indeed, during a great part of the time this pipe was disconnected, the oxygen being taken from a reservoir and discharged into the air. A constant circulation of the same body of gas from the pump to the machine and back is, in fact, no essential feature of the design. If "Zero" or anyone else doubts this I refer him to Hampson's specification. CRYOS.

May 26th.

RADIATION AND BOX-COIL CONNECTIONS UNDER THE MILLS SYSTEM.

SIR,—The forms of radiator connection herein described have been used with success by me, and may be of value to others. In the Mills system of heating, steam is taken from boiler direct to top of the building, then piped off to a number of "risers" which drop through the various stories and terminate in return pipe in cellar. Radiators are usually supplied from these risers by single pipe connections. The connections here shown will, however, work equally well on any other one-pipe system.

Fig. 1 shows the usual connection for wall coils. Mr. E. E. Magovern* has pointed out the defects of this form, and recommends connections as in Fig. 2. I can confirm Mr. Magovern's statement that Fig. 1 is very defective; in fact, cannot be made to heat up the whole radiator. I then independently worked out Fig. 2, but it also was found very defective, unless the coils are quite small, and the steam pressure very steady. In case of coils containing 60 to 85 square feet of radiating surface, there would be such violent pounding under ordinary fluctuations of steam pressure that these coils had all to be shut off.

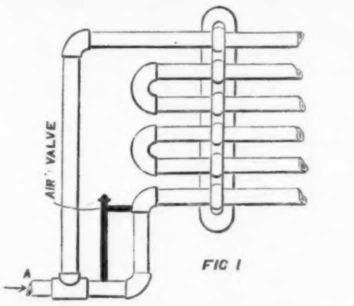


FIG I

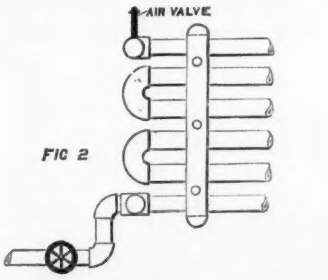

FIG 2

Fig. 3 shows the result of the experiments made to correct this trouble. I am familiar with the use of water seals in heating, and have myself often used them, but the precise arrangements here described are new to me, though doubtless known to others. It is evident that the water seal causes the arrangement to work exactly as in a two-pipe system, except that the return water flows from the top along the bottom of the horizontal connecting pipe. The drawing shows sizes of pipe used for coils two to three pipes deep, eight high, and 8ft. to 11ft. long, all 1¼in. pipe. A 1½in. supply would be better, but in this case 1¼in. was used, owing to size of outlet in the riser.

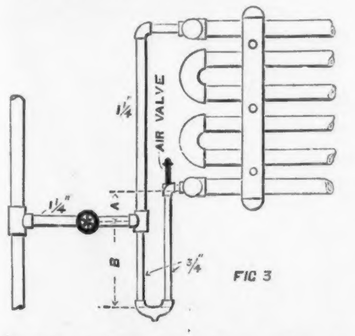

FIG 3

The only precaution to observe in this connection is that the distance *A* must be greater than the head of water equivalent to the maximum drop of pressure between the supply and return pipe of the coil. The writer has found that in all his work 7½in. is ample. Distance *B* should not be less than this; in the work under question it was anything from 7½in. to 14in. Gate valves must be used; globes will not answer. If the fitting is well done, and the supply pipe has a little fall, the radiator will be noiseless under any changes of steam pressure.

I do not like to have steam and water going in opposite directions in horizontal pipes, unless they are very short, hence I have designed connections as in Fig. 4, to be used when the radiator is more than 3ft. from the riser. The dimensions of the trap should, of course, be the same as in Fig. 3. When it is possible to use this design I prefer it to Fig. 3, even when coil is quite near the riser.

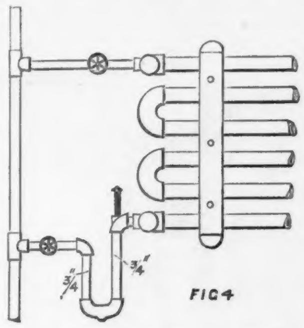

FIG 4

Some object to the one-pipe system because of the pounding when a radiator is turned on, and the boiling or gurgling sound frequently heard when the radiator is in use. I have had to consider cases where such troubles existed, and it was decided to apply the principle underlying Figs. 3 and 4. Fig. 5 shows the result of the experiments, and it completely cures the evils. Everything works as in a two-pipe system; water and steam go in the same way, the circulation is rapid, and the radiator is noiseless. A return bend with ¾in. back outlet was used in the bottom of the traps, and into outlet was screwed a capped nipple, or a bushing and pet-cock. These traps have never given trouble except in one case, where the fitter carelessly left in the pipe enough chips to plug up the bend.

I have given the above connections two years' trial, and found them highly satisfactory if the work is properly done. The scheme is superior to the two-pipe system, in so far as it is impossible to flood the radiator by leaving open the return valve. If this be done in Figs. 4 and 5 the steam pressure will drive the water in the trap up into the radiator, and make a very decided noise before the party who closed the steam side can get very far away, and it thereby gives warning that the return is open. I consider this a valuable feature, as I have seen numerous cases where in a two-pipe system the flooding of radiators, and consequent leakage around valve stems and through air valves, has seriously damaged furnishings in houses, and books and apparatus in schools.

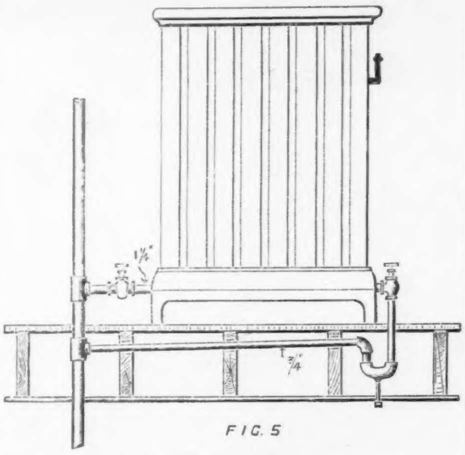

FIG. 5

In the Engineering Hall, Michigan Mining School, cast radiators are used on the second floor, part of them with ordinary one-pipe connections, and part connected as in Fig. 5. On the first floor—shops and lavatories—coils are used, all connected as in Figs. 3 and 4. In the basement—shops—coils with regular two-pipe connections are used. The relative performances of these have been carefully watched, and the connections here described are in this case considered preferable to the others. EDGAR KIDWELL.

Michigan Mining School, Department of Mechanical
Engineering, Houghton, Mich.,
May 20th.

THE PROBLEM OF SPEED.

SIR,—This is largely a question of quality of fuel. Monsieur Normand has doubtlessly constructed the fastest vessel afloat for short runs. Here is a boat only 144ft. long which, on an hour's run, has logged 31 knots. This is a much better performance than that of another boat 210ft. long which does 30 knots, because the square roots of the respective lengths point out the proportionate speed of similarly proportioned vessels with proportionate power, and, consequently, the 210ft. boat should have had a speed of 37 knots, with power in proportion to her tonnage. The Forban required about 4000-horse power, and so the 210ft. boat would have required about 11,000-horse power to go at 37 knots speed. This is probably about double what the 210ft. boat really had to dispose of.

I leave it to naval officers to say of what use such a small vessel as the Forban is likely to be, considering that one half her displacement is taken up with machinery and that her bunkers will only contain about 15 tons of coal. The British Admiralty compels contractors to use ordinary coal on trial-trips, and on low-speed consumption trials the fire-grates must not be materially reduced. Not so in France; there the low-speed consumption trials, which determine the quantity of coal the bunkers must contain may be made with very largely reduced grates, and thereby of course, a considerable economy is attainable. Again, in France contractors are allowed to use a special class of fuel, viz., briquettes made of pulverised coal, out of which the earthy particles have been carefully washed, the coal being then mixed with certain tarry substances to make it cake in the process of hard pressing into briquettes. By such means it is possible to manufacture a fuel which far surpasses Welsh coal in power. It would be very interesting to try what speed could be got out of the Forban on a *three* hours run—not one hour—with ordinary Welsh coal, say Nixon's navigation. I fancy that 28 knots would be more likely than 31, for after a short time the bars would be nicely clinkered over when burning at the rate of probably one hundredweight per square foot of grate per hour. The total duration of the Forban's trial seems to have been about one and a-half hours only. In England a three hours' trial is exacted.

I should consider the Forban as more of a beautiful scientific toy than a practical sea-going vessel. All honour to M. Normand for having schemed out the combination of lightness and power, but I should be sorry to see our naval authorities spending public money on such awfully complicated little machines, which, like racing bicycles, are fast on a track, but useless on the road.

June 1st. PRACTICAL MARINE ENGINEER.

PERMANENT WAY.

SIR,—In all the correspondence on this subject no one, as far as I have seen, has called attention to the fact that in the United States the sleepers are all white oak on good roads like the New York Central. This timber holds the spikes and is hard enough to carry the sole of the rail without crushing. To my mind the American road seems to be superior to the English one, as it is made more directly and of fewer parts. Mr. Whitestone's suggestion of steel sleepers, if adopted, would of course make our roads as simple and as easy to keep in order as the American roads are; but if our roads follow American improvements no faster than our rolling stock has done, I fancy only those who are now lads will see the change carried out.

The fact is the manufacturing monopoly enjoyed by England for fifty years after the invention of the steam engine begat a spirit of ignorant self-sufficiency in the nation at large, too much of which survives to the present time, and some of which is not quite absent in the councils of the powerful corporations which manage our railways. R. R. GUBBINS.

London, S.E., May 30th.

SIR,—Would it be unreasonable to suggest to your correspondent "Anglo" that he should read letters before he criticises them. I have never condemned the English system of chairs; it would be an impertinence for a layman to express positive opinions on engineering matters in a technical journal. The bulk of my letter was merely the report of the opinions of American experts which, as I expressly stated, I heard with surprise. The only opinion I expressed was that our English system could not be the only possible system of constructing a first-class road, seeing that the Americans construct undeniably first-class roads on a different system, which they believe to be actually a better, as it is certainly in America at least, a cheaper one.

To answer "Anglo's" question—"tie-plates" being comparatively thin and light, obviously do not produce the same rigidity as a solid 45 lb. chair. Further, the best roads do not all believe in even tie-plates. The Pennsylvania, I understand, never uses them; and no road, as far as I am aware, employs them when it can get hard wood sleepers.

To your second correspondent, "C. Trenail," I would say that I should need to lose my head pretty completely before I did as he appears to have done, and confused together great trunk lines like the Pennsylvania, the New York Central, the B. and O., &c., and the pioneer lines in unsettled districts of the South and West. If "C. Trenail" can produce evidence that derailments, owing to defective permanent way, are "enormously more numerous" on the Pennsylvania than on the London and North-Western, we can begin to discuss the reason. Till he does it is useless to argue from lines which are no more typical of the best American practice than the Manchester and Midland, or the Central Ireland, are typical of the standard of the great main lines here.

47, St. George's-square, S.W., W. M. ACWORTH.
June 2nd.

TRACTION ENGINES.

SIR,—"Traction Engine Admirer" seems to be only an occasional observer of matters affecting the objects of his admiration. The "Select Committee on Traction Engines" to which he refers began by hearing eight or ten engine users and makers, who gave evidence from all parts of the country in support of the requests put forward by this Association for increased facilities for steam road locomotion. The road authorities are not by any means the traction engine haters your correspondent imagines them to be. All recognise the necessity and utility of steam road locomotion, and many gave most valuable answers to the various questions put to them by the members of the Select Committee, which must help our cause.

The debt of gratitude which the trade owes to the members of the Select Committee for their painstaking efforts will be obvious when the report and evidence are published.

H. R. SUMMERS, Secretary.
National Traction Engine Owners' and Users' Association,
5, Laurence Pountney-lane, Cannon-street, E.C.,
June 3rd.

WOOD PAVING.—At a meeting of the Vestry of the parish of Paddington held on Tuesday, the report was discussed of a special committee appointed to consider the whole subject of wood paving in the parish, more especially in regard to any renewals, being brought within the limits of a specified amount. The report stated that the committee were unanimously agreed as to the imperative importance of hard wood for public thoroughfares, and they entirely endorsed the words of Mr. J. P. Norrington, Assoc. M. C.E., "that it is a wicked waste of public money to pave a line of heavy traffic with soft wood." The committee having seen sections of roadway paved with jarrah, karri, and other hard woods, subjected to most severe traffic, consider that the length of life of these woods have not been over-estimated, and that fifteen years is within the limits of trustworthy probability. The committee state that they entertain very decided views as to the sanitary superiority of the eucalyptus woods and their non-absorbent qualities. As to the first cost of hard wood, they have had clear evidence that its great durability would not only cover the additional expense, but would realise an actual saving in the course of years, as well as make the necessity for renewals far more exceptional than could be possibly attained by the best treatment of the soft woods. This exemption from frequent renewals would be one of the greatest possible boons to shopkeepers in busy thoroughfares.

ENGINEERING SOCIETY, KING'S COLLEGE.—At a general meeting on May 29th, the President—Mr. Mowat—in the chair, Mr. Fletcher read a paper on "Telescopes: their Construction and Revelations." The author dealt briefly with their history, and the theory of lenses. He then went on to detail some of Galileo's experiments to obtain a more efficient instrument. He pointed out the difficulties encountered by Galileo and his contemporaries, owing to chromatic and spherical aberration. After explaining the physical cause of these, Mr. Fletcher indicated some of the earlier attempts to correct these faults in telescopic instruments. He also showed how that in such attempts the length of the telescope greatly increased—finally reaching 123ft.—as it was found by increasing the focal length of the lense, aberration was greatly diminished. The author then discussed Sir Isaac Newton's telescopes, their mechanism, and the way in which achromatism—thought impossible by Newton—was finally obtained by Dollond. He then illustrated several modern forms of astronomical telescopes, and the mechanism by which the object glass of the instrument is made to trace an exactly similar and proportional curve to that described by the star from rising to setting. In describing the clock-work used for this, Mr. Fletcher pointed out how the somewhat jerky action of the pendulum was replaced by that of a vane revolving in a cup of mercury. The bearings on the instrument were also dealt with fully. In dealing with lenses, he showed the increase in size of lenses during recent times, having arrived at as much as 40in.; but Mr. Fletcher pointed out this was probably near the limit, as its great size and weight made it exceedingly susceptible to any stresses due to the mounting, or even unequal heating, and its use required the greatest care and delicacy. Messrs. Mowat, Standen, Tolmé, and Bailey joined in the ensuing discussion.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number)	*£0 14s. 6d.*
Yearly (including two double numbers)	*£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate or any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—	
Half-yearly	*£0 18s. 0d.*
Yearly	*£1 16s. 0d.*
THICK PAPER COPIES—	
Half-yearly	*£1 0s. 3d.*
Yearly	*£2 0s. 6d.*

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

ROYAL INSTITUTION OF GREAT BRITAIN.—Friday, June 19th, at 9 p.m.: Paper, "The Utilisation of Niagara," by Mr. Thomas C. Martin.

THE CHAMBERS OF COMMERCE OF THE EMPIRE.—June 9th and following days.

MUNICIPAL ELECTRICAL ASSOCIATION.—June 10th to June 12th, at the Royal United Service Institution.

THE ENGINEER.

JUNE 5, 1896.

OUR HORSELESS CARRIAGE COMPETITION.

WE have offered prizes amounting in value to eleven hundred guineas, in order to promote the establishment and development in this country of an industry which cannot ultimately fail to attain very considerable, if not enormous, proportions. But little reflection is required to make it clear that it would be not only possible, but very easy, to spend this money and yet attain no useful result of any kind. We are not sure that this aspect of our competition has been fully and generally understood, and we think that the time has arrived when we should offer certain explanations to our readers, and direct their attention to facts which they may have overlooked. Our intention, and that of the eminent engineers who have consented to act as judges, is that the competition shall produce not only vehicles of some sort capable of travelling long distances at a moderate speed without accident, but vehicles sufficiently good to satisfy the conditions certain to be laid down by purchasers —that is to say, by the public at large. It forms no part of our purpose to go over old ground. The experiments made in France have left no doubt on the minds of those who have read what we have written concerning them that a very considerable measure of success has been attained. They have proved that light oil engines can be used for the purpose of locomotion. Now our competition is not intended to prove that what has been done on roads in France can equally well be done on English highways. That would be entirely superfluous. What we wish is to see some material advance made, we shall not say on French or American practice, but on what has been accomplished up to the present. We have been careful to keep our readers apprised of all and everything that is being done in the production of horseless carriages. We have ransacked the pages of history; we have dealt with every form of self-propelled vehicle for common roads. The exhibitions at the Crystal Palace and at the Imperial Institute contain, it is believed, the very best horseless carriages in the world. But a careful examination of these vehicles leads to but one conclusion, namely, that nothing nearly suitable to the demands of the English public has yet been produced. On the one hand, so far, no vehicle has been made to run using the heavy oils, without producing a very disagreeable smell. They are more or less imperfect, crude machines; full of promise, full of possibilities, but totally unfit to put into the market. On the other hand, the carriages which run with light oil, petroleum spirit, benzine, or naphtha, although even elegant in design and sumptuous in finish, do not at present comply with the law of Great Britain, and render necessary the storage of a highly inflammable liquid, in a way that would set the insurance companies up in arms. The petroleum spirit must be stored in very small quantities by those who sell it. It can only be purchased in comparatively few places. Anyone using a light oil motor must keep a store of the spirit in his coach-house or near it, and this he could only do by making special arrangements with the insurance companies. Very considerable commercial difficulties stand in the way, and will prevent in this country the light oil carriage from attaining any popularity unless considerable changes are made in the law and improvements are effected in the method of storing petroleum spirit. All which is much to be regretted, because the advantages which it possesses over the heavy oil are at once indisputable and considerable. But this is not all.

We do not think it can be said that any fairly satisfactory carriage has yet been produced. A visit to the Crystal Palace or the Imperial Institute will convince the most enthusiastic that, one and all, the vehicles are noisy, and that, one and all, they leave behind them most objectionable evidence that they have passed. In the matter of vibration, again, some of them are simply intolerable. Now, the general public will not buy carriages, either for pleasure or for business purposes, which are not at once safe, comfortable, odourless, and silent. It is not at all probable that a useful vehicle, say one suitable for carrying a doctor on his daily rounds, will be obtainable for less than £250 or £300. A man who can afford to sink so much capital will demand a certain degree of comfort in return; and he will not be content to ride about the country in a vehicle which will shake him and itself to pieces, or whose running can be heard half a mile off. We know that some thoughtless folk believe that finality has been reached, and that such vehicles as those now to be seen are as good as can be produced. We are quite certain that is not the case, and that in a little time great advances will be made, and vehicles produced which will compare with those now in use much as a Great Northern locomotive does with the Rocket.

The views we have expressed are entertained by a large number of those engineers and others much interested in the development of the horseless carriage. From all parts of the kingdom we have received requests to postpone our competition from next autumn until a convenient season next year, and we confess that the arguments used are very difficult to resist. It is pointed out that the horseless carriage is a new thing with the present generation of engineers. That it is essential that something much better than anything yet made must be produced if a popular demand is to be established; and that to all intents and purposes our prize competition has come too soon—much before anyone is ready to take advantage of it. The result of our inquiries is that there would be no probability of a contest amongst British makers if the competition were held in October; and that all the foreign vehicles are excluded by the nature of the oil they use, from taking part in any portion of the competition but that for the supplemental prize of 100 guineas, which we have offered for vehicles using light oil or petroleum spirit. It is pointed out that the proposed great French race has had to be postponed; and it will be remembered that both the attempts recently made in the United States to bring about a satisfactory competition proved abortive. For ourselves, we have been extremely reluctant to postpone the competition; but, in point of fact, the question has been settled for us. Besides verbal communications, we have received a large number of letters inviting us to postpone the trials. We have printed two, the others are all more or less on the same lines. We have only received one letter the other way. The requests to postpone have, therefore, been practically unanimous, and with the full approval of the judges we accede to it.

There is moreover another factor, which cannot be overlooked. Although Lord Harris's Bill has passed Committee in the House of Lords, there is quite a possibility that it may not become law this session. The Government have their hands full, every moment appears to be pre-engaged, and the chances of the Bill slipping quietly and quickly through are very small. We hear with regret that certain highly injudicious friends have suggested amendments, the introduction of which would be, we have no doubt, opposed. The carrying out or not of our competition depends of course on the passage or non-passage of Lord Harris's Bill. It may be said, and perhaps with reason, that it is too soon to say in the first week of June that a competition cannot take place at the beginning of October. But we hold that the best interests of intending competitors will be considered if we announce at once that the trials will not take place until 1897. We believe that this will satisfy many inventors who are now spending much time, talent, and money, on the production of vehicles which they intend to be superior in every respect to anything yet produced. All they ask for is time. It would be a most unsatisfactory termination to our undertaking if the vehicles winning our prizes were themselves superseded in a few months by something very much better in all respects. It does not appear that anything can be lost by a delay of a few months, and we feel certain that in postponing the competition we shall not only meet the wishes of intending competitors, but promote the best interests of the Horseless Carriage.

THE LIGHT RAILWAYS BILL.

THIS Bill, which has been considered at great length by the Standing Committee on Trade, was made, in the Report stage, the subject of a long and entirely useless debate in the House of Commons on Monday night. Amendment after amendment was moved, and the House divided seven times, the opposition always being beaten by enormous majorities. We do not say that the amendments were invariably frivolous or purely obstructive; but it is useless to expect that any important change will be made in a Bill which has passed the Standing Committee. We have, however, already said that this is in many respects about the worst drawn Bill ever laid before the House of Commons, and before it becomes law it is earnestly to be desired that the Government should give way—the Standing Committee to the contrary notwithstanding—on one most important point, and define the meaning of the words "light railway." What is a light railway? The question will have to be settled every time a scheme is brought before the Commissioners. The theory is that the Commissioners are to say what is and what is not a light railway. No system is more fraught with evil, or causes more waste of money, than that which leaves the meaning of the words of an Act of Parliament open to individual interpretation and discussion. If Parliament is unable to define its own meaning, how is it possible for any judge, commissioner, or lawyer to do it? We have here a Bill which limits the powers of interference of the Board of Trade, and removing a number of rules and restrictions, almost revolutionises Parliamentary procedure as affecting the construction, working, and financing of railways. Evidently it is not the intention of Parliament that the Act should apply to normal lines, and yet no attempt is made to define to what roads it shall and shall not apply. Let us suppose that a scheme is got up for running a line which any one of the existing companies may regard as a competitor. Opposition will be commenced, and the very first step taken by opposing counsel will be to assert that the proposed line is not a light railway within the meaning of the Act, and that the commissioners have no jurisdiction. Here is a splendid opportunity for endless litigation. On the other hand, a so-called light railway is proposed which will, as before, enter into competition with an existing line. Its gauge will be 4ft. 8½in.; the speed allowed unlimited; the weight of the rolling stock just a little less than that of the recognised main line; a 75 lb. rail is used instead of an 84 lb., and other things are in proportion. This is called a light railway by the promoters; and these gentlemen secure advantages in consequence, and enjoy privileges simply in virtue of the name. Can anything be more unfair to existing companies and shareholders? Will any railways be made in future, in Great Britain, which do not come within the four corners of the Act? It seems absurd to suppose that branch lines, at all events, will be made under any other Act of Parliament. Of course Parliament is not supposed to contemplate this.

Some of the members who took part in the debate appeared to think that a light railway must be of less gauge than 4ft. 8½in. As an example, we may cite the argument of Mr. Logan, the member for Harborough, in Leicestershire, who "entered his protest against the removal from light railways of those restrictions and regulations which the Board of Trade had found necessary for the protection of the public. It seemed to him a serious and dangerous new departure, and he hoped the President of the Board of Trade would thoroughly realise this. As to the question of gauge, he hoped it was not too late to insert a clause declaring that all railways constructed under the Act should be of the 4ft. 8½in. gauge, so that they might join up to the existing railways."

At one stroke Mr. Logan would render the Act totally useless for its intended purpose. Sir W. Hart-Dyke, on the other hand, could not imagine anything more destructive to the Bill than the fixing of the gauge. Yet he had no hesitation in suggesting a most impracticable and unpractical definition, namely, that nothing should be deemed a light railway on which a speed was attained greater than 12 miles an hour. There is, of course, no reason whatever why speeds of 25 miles, or even 30 miles an hour should not be attained; and to limit the velocity to 12 miles an hour would go far to render the light railway worthless. It is to us extraordinary that the Act does not contain such words as these: "The words light railway shall mean a railway worked by vehicles which shall not weigh loaded more than four tons for each axle," or "the greatest load that may be carried on a light railway shall be four tons per axle." This definition would be found in practice quite sufficient. No engineer in his senses would construct a heavy line to carry such small loads. A road constructed to carry but two tons per wheel could not possibly come into competition with a normal line, for reasons which it would be sheer waste of time to place before our readers. We do not, of course, pin our faith on four tons per axle, but under no circumstances would we allow the weight to rise above five tons, which is about that of most goods wagons on main lines. We do not refer to coal or mineral trains, which carry much more. A four-coupled engine with eight tons on the driving wheels, or a six-coupled engine weighing twelve tons, is quite heavy enough to work any traffic which would devolve properly on a light railway. In no fit sense of the word can a line of, say, 3ft. gauge, worked by a 30-ton tank engine, be called a light railway, much less a line 4ft. 8½in. gauge, worked by locomotives of the same weight and laid with 60 lb. or 65 lb. rails. Yet it would be very difficult to prove that the Act did not apply to such a line. Indeed, we happen to know that many persons always confound narrow gauge and lightness, holding that a line laid to the normal width must be "heavy," while any line narrower must be "light." It is anticipated that the Commissioners will decide in every case what is and is not a light railway; yet it is certain that they must either prepare some hard-and-fast rule for their own guidance, or their decisions must be mere expressions of opinion. To the average intellect it seems fatuous to pass an Act of Parliament, and to leave it an open question whether it does or not apply to any particular case. No hardship would be inflicted by defining the light railway with sharpness; and even if in a few cases it happened that heavier rolling stock than we have named could have been used to advantage, the loss would be so small that it would be as nothing compared to the advantage gained by removing all doubt from the minds of promoters as to what will and will not be accepted as a light railway by the Commissioners. Fortunately it is not yet too late, and we venture to hope that such representations may be made on this point to the Government as will induce them to give way, and say what they mean by the term "light railway." At present it is quite clear that Parliament has arrived at no conclusion on the subject.

PERMANENT WAY.

Among the numerous correspondents who have written on the construction of permanent way in our pages during the last few months, there is not one who is not qualified to express an opinion based on a competent knowledge of the subject; therefore what they have to say deserves thoughtful consideration. Although they have in many instances withheld their names from the public, it is no breach of faith to say that they include in their ranks the platelayer and the locomotive superintendent, the inventor and the civil engineer. None of these pronounce English permanent way perfect. The general drift of opinion is in favour of a return to the old-fashioned flat-footed rail spiked to cross sleepers, and we are assured that lines made thus are most successful in the United States. It is noteworthy, indeed, that no one seems to have a good word to say for continental lines. The American track first and the English second appears to be the classification most in force. We have on a previous occasion directed attention to what ought to be, but evidently is not, an obvious truth, namely, that the price to be paid for the road and for its maintenance is an important factor to be considered when we are balancing the advantages and disadvantages of various systems of constructing permanent way. We have heard a great deal lately about safety and danger, risk and accident; and we have been told that the English road is a feeble road, and not able to bear the great weights and high speeds now in vogue. No statistics, however, have been produced to prove the proposition. It is true that one or two bad accidents have occurred, presumably for lack of proper or sufficient ballast; but there is no evidence to show that the flat-footed rail on cross sleepers would be better in this respect than the normal track. When we remember that the London and North-Western Railway, for example, has a train mileage of about 40,000,000, or 125 times the distance from the earth to the moon, per annum, while the derailments are practically nil, we think it may be admitted that our roads are really safe. In the United States, on the other hand, derailments are very common, and constitute a very fatal class of accidents. Not much seems to be needed to make our roads absolutely safe. Probably a certain number of anchor plates, as suggested by one correspondent, fixed to sleepers on curves, would supply all that is needed. We fancy that none of our correspondents is prepared to maintain that any system of permanent way can be devised which will be independent of repairs and inspection. However excellent a road may be at first, it will deteriorate unless looked after and maintained in good condition. It would seem, then, that after all, the arguments in favour of the American as compared with the English road, are more matters of opinion than of fact so far. It is admitted that derailments, save at points and crossings, and in yard work, which do not count, are very rare in this country; but we are warned that this will not always be so; and thus, finally, the principal fault found with English track is that its maintenance is costly, that its surface is rough, and that the chairs are bad for the rolling stock.

Two alternative systems of construction are proposed. One is the flat-footed rail and longitudinal sleeper; the other is the flat-footed rail and transverse sleeper. Concerning the first, it is enough to say that it was tried for many years on the Great Western Railway. Everything was done with it that could be done to make it a success. It has all been taken up, and the whole road save a few insignificant bits, has been relaid with chairs and cross sleepers. Some of our correspondents must excuse us if we say that the engineers of the Great Western Railway knew better than anyone else what was the best road. The continuous line has disappeared for very sufficient reasons, and can no longer be regarded as falling within the bounds of practical railway engineering. We have, then, the flange rail laid on cross sleepers. That, too, has had an exhaustive trial in this country. Its great defect is that, weight for weight, it must have less vertical strength than the bull-headed rail. Its advocates cannot get over this fact, and accordingly suggest that instead of using an 80 lb. or an 84 lb. rail, one weighing 100 lb., or even more, per yard should be adopted. They seem to forget, however, that there is in existence already a 100 lb. bull-headed rail, Sandberg's section, which is in turn very much stiffer than the 100 lb. flange rail can be; and they are quite silent on the subject of cost. If our correspondents will try to place an order for 10,000 tons of adequate flange rails, they will very soon find a noteworthy difference in the price. The bull-head and double-headed sections are very easy to roll, and scarcely any wasters are produced; but the rolling of big flange rails is quite another matter. The percentage of wasters is considerable; the weights that can be turned out per week smaller, and the difficulties of rolling increase with the dimensions of the section. The result is that flange rails will cost more per ton by some shillings than the ordinary section. Certain of our readers doubtless recognising this truth, overcome the difficulty by using a flange rail of moderate weight, and increasing the number of sleepers. In short, it is proposed, to all intents and purposes, to construct a timber platform, and carry the rails on this. We are told that in the United States the flange rail is a great success, and in almost the same sentence that nearly twice as much wood is used as we use. Our correspondents omit to add that the United States abound in forests, and that the value of the timber is very small, while we have to import every sleeper we use. The cost of permanent way would be very largely increased if we doubled the number of sleepers; and we have yet to learn what form the return for this outlay would take. In what way would the London and North-Western Railway Company, for example, be reimbursed if it doubled the number of sleepers in every mile of its track?

It has been pertinently asked, Whence came the normal road with chairs? What is the history of the evolution of normal English permanent way? The reply is that, like many other things in engineering, it is a survival of the fittest. Not, be it observed, necessarily a survival of best, but only of that best adapted to the conditions of British railway life. The flange rail has a great defect, overlooked altogether by most of our correspondents. It tends to turn over on its outer edge under the bursting stresses set up by the engines. It eats its way into the sleepers, draws the inside spikes, becomes loose, and gives — especially on curves — an inordinate amount of trouble. This is due to the comparative narrowness of its base. Any attempt to make the rail stiff by adding to its depth aggravates the evil. In the United States the sleepers are mostly of oak or hard wood, the price of which in this country is prohibitive. To get over this difficulty the chair was introduced. It gives a very wide base to the rail, which is therefore secure against turning over. This is the principal reason why chairs were introduced and used; and there is this further and enormous advantage, that no system exists which allows of a rail being removed and replaced with such facility. The flange rail on a cross sleeper road can only be a success when the sleeper is made of hard wood.

While we advance these facts in favour of the normal method of constructing permanent way, we have no intention of asserting that improvements may not be effected on many of our lines; but the direction in which these improvements should proceed has little or nothing to do with the rails The crying defect on some of our roads is bad ballast. In many places the ballast has been worked and worked until it has had "the life taken out of it." It is dust in summer, mud in winter. Bad ballast is a constant source of expense. Packing up has to go on almost day and night if the road is to be kept at all even; engine springs are broken; the engines and rolling stock generally are knocked about, and there is always a certain amount of risk incurred. It is not the sleepers, nor the rails, nor the chairs, against which our correspondents should direct their attack. It is against ballast—worn-out ballast in some cases; bad ballast to begin with in others. We have already said that railway companies are very slow to lead ballast from a distance, and in this they are penny-wise-and-pound-foolish. Engineers, locomotive superintendents, track men, gangers, platelayers, engine drivers, are one and all agreed that good ballast will cover a multitude of defects on the one hand, and that, on the other, nothing can compensate for the injury done by bad ballast. The argument that by having plenty of sleepers any stuff will do for a road bed, is nonsensical. We may have so many sleepers that the road cannot be properly packed, and the remedy becomes worse than the disease. Anyone who has seen, as we have, a close-sleepered road, with half the sleepers hanging from the rail because of the running of the sludge, falsely called "ballast," under them, will be slow to find in wood a substitute for good gravel or broken stone.

Finally, we may say that we do not share in the apprehensions of some of our readers. Speeds, no doubt, augment, and the loads carried are heavier; but as regards the latter, it must not be thought that the locomotive superintendent or the designer of coaches has stood still. Locomotives are provided with means of easing their progress round curves to a far greater extent than was the case twenty years ago. We find the traversing bogie in regular use, or, at least, the traversing axle. We do not think the loads per wheel have augmented. It was said that some of Mr. Sacré's engines on the Manchester, Sheffield, and Lincolnshire Railway carried 21 tons on their single drivers eighteen or twenty years ago. Nothing heavier than that, or indeed as heavy, is running now, so far as we are aware. We do not see any reason, therefore, to think that radical changes of any kind will be needed in English permanent way to enable it to meet the demand which will be made on it in the near future; but we know that much ballasting ought to be, and probably will be, done anew. The cost may be considerable, but no money can possibly be spent on a railway which will bring in so certain a return. In the long run it would pay all our leading railway companies to ballast their lines from end to end with broken stone. The cost would be great, but the return would be great in proportion.

LITERATURE.

The Naval Annual for 1896. By T. A. Brassey. Griffin and Co., Portsmouth.

[First Notice.]

The only feeling of regret that we experience, on opening the *Naval Annual* for 1896, is that its pages no longer contain those crisp and valuable papers upon burning nautical questions that have emanated, for ten years, from the pen of Lord Brassey. Nevertheless, the able compiler of the *Annual* has introduced into it this year a series of novel features and papers upon technical subjects that cannot fail to awaken interest. The excellent engravings, showing side views and deck plans of the Powerful, the Andromeda, or Diadem class, the Buenos Aires, the Carnot, and the disposition of armour upon the Brennus, are of themselves not the smallest of the attractions which the book contains. Whilst writing upon this point, we would make a suggestion which we feel assured would be acceptable to many of the supporters of the *Annual*. We take it for granted that the plates and tables in this work are that which has the main interest for technical readers, and yet it is very difficult to form an accurate estimate, from the plates, of the relative value of the battleships and cruisers of different nations. In the earlier plates it was customary to give a midship cross-section, and sometimes two or three other sections of the various vessels illustrated, showing roughly the position of the propelling machinery and boilers, the magazines, barbette, and turret mechanism, &c.—such, for instance, as were given in the case of the Jauréguiberry. Plates of this character would be of much greater value, if obtainable, than mere side views of ships, which give no insight whatever into the novel characteristics appearing in such vessels as the Diadem and Powerful. Had a midship section of the Powerful been in possession of the public a year ago, the ridiculous rumour that the Admiralty was building docks into which the new cruisers could not be floated would never have arisen. It is clear that if plates of side elevations and plans may be published without injury to the public interests, cross sections may be published too.

Chapters I. and II. deal with the progress of our own and foreign navies. The following brief table, showing, in a few figures, the relative results obtained during the steam trials of the Majestic and Magnificent, as representative of the two great systems of forced and induced draught, show how nearly the systems approximate:—

Eight Hours' Natural Draught.

	Mean draught. ft. in.	Air pressure. in.	Mean revolutions.	I. H. P.	Speed.
Majestic	25 0	—	100·5	10,418	16·9
Magnificent	24 11½	1·4	96	10,301	16·5

Four Hours' Full Power.

	Mean draught. ft. in.	Air pressure. in.	Mean revolutions.	I. H. P.	Speed.
Majestic	Not known	Not known	106	12,497	17·9
Magnificent	24 8½	0·9	100·3	12,157	17·6

Thirty Hours' Coal Consumption Trials.

	Coal consumption. lbs. per I. H. P. per hour.	lbs. of steam.	Revolutions.	I. H. P.
Majestic	1·84	135	85	6075
Magnificent	1·67	133	83	6086

It will be observed that there is an economy of fuel in the case of the Magnificent, with the system of induced draught—taking into consideration the loss of two revolutions—amounting to about 0·15 lb. per indicated horse-power per hour, or about ten tons per diem at this speed.

A good description is given of the Powerful and Terrible, showing some of the constructive features. It is observed that the armoured deck is "composed principally of three thicknesses of steel plating, but at the edges, where it joins the side of the ship, two of the skins of plating are discontinued, so that the extreme edges of the deck, for a width of a foot or two, are only one skin of plating." Should this be a correct description, it cannot but be a matter of regret that the old system of framing and construction has been departed from in the case of these great cruisers. The plan of allowing the thick armoured deck to extend to the skin plating on both sides of the ship, and securing it to the deep bracket-framing beneath, and then building the frames of the main and upper deck portions immediately upon this firm basis, appeared to be a very sound one.

Notice is taken of the very excellent results which have been obtained with the recently renovated battleships, notably with the Monarch and Sultan. The former of these two vessels attained the remarkable speed of 15¾ knots upon her trials, and the latter under natural draught ran for eight hours at a mean speed of 14·6 knots. These ships are now considerably more powerful both in speed and armament than they were originally, the quick-firing 4·7in. guns of the Sultan having added specially to her fighting value; but it does seem a pity that, when so much was undertaken in regard to these and other similar vessels, and so much money spent, the old armament was not replaced altogether. This is being done with renovated vessels in Italy, and there is no reason why it should not have been done in England.

The progress made in the torpedo boat destroyers of the Desperate class is very satisfactory. Before the end of the year we shall have about thirty of these invaluable adjuncts to our torpedo boat flotilla completed and afloat, each of 5400 indicated horse-power, with a speed of 30 knots. When it is remembered that they are expected to overtake and destroy torpedo boats, which are rapidly increasing in power and speed, the importance of each knot beyond 25 per hour may be realised. We understand that Messrs. Laird, of Birkenhead, have several of these 30-knot boats in hand, in addition to the ten ordered for the British Government, so it is clear that other nations are waking up to the importance of the class as well as ourselves.

In France there is not quite so much to record as usual, the difficulties that have been met with by the French naval constructors in securing that their completed battleships shall be sufficiently stable in a seaway having diverted their attention to alterations of superstructures and fighting masts and cutting down upper works rather than to building fresh ships. The extraordinary system of continued modification which prevails in France from the time when a war vessel is originally designed to that when she proceeds upon her first commission, is strikingly seen by a comparison of the plate of the Brennus, which appeared in the *Naval Annual* some six years ago, with that of the finished vessel in the *Annual* for this year. One of the most striking features in regard to nearly all the ships now building and completing in France is to be found in the fact that nearly in every case are they to be fitted, or are already fitted, with water-tube boilers, either of the d'Allest, Belleville, or Normand type. It is a matter for congratulation that our Admiralty, although prepared to make exhaustive trials of the water-tube system, is content to be possessed *of* ideas upon the subject, and not *by* ideas, as in the case of our neighbours across the Channel.

The Jeanne d'Arc will be a vessel emblematic in every way of the name of the heroine after which she is called. She is to be an armoured cruiser of 11,270 tons, with 28,000 indicated horse-power, and maximum speed of 23 knots. Belts of 6in. and 3in. steel extend to the deck above the armoured deck. The armament comprises two 7·5in., eight 5·5in., and twelve 3·9in. quick-firers, as well as smaller weapons.

In Italy the armoured cruiser Vettor-Pisani has been launched at Castellamare. She is only of a displacement between that of the Edgar and Eclipse—6500 tons—but is very powerfully protected, there being a partial nickel steel belt at the water-line, and above this a long redoubt for eight 6in. quick-firers, protected by 6in. plates. The deck, forming the upper portion of this battery, is covered with 2in. plates. Besides this, there is an armoured deck of 1½in. and 1in. plates, extending the whole length of the ship, and 6in. bulkheads at the end of the redoubt. Four 6in. quick-firing guns are on the upper deck, and six 4·7in. quick-firers are mounted in other places. The redoubt has its gun positions isolated by splinter screens. The indicated horse-power is to be 13,000, and speed 20 knots; coal capacity, 1000 tons. This vessel, if a good sea-boat, should be a disagreeable adversary for one of our first-class cruisers to tackle.

The performances of the Sicilia during her natural draught trials were very remarkable. The mean speed run on a base of 100 miles—fifty out and fifty home—was a little over 19·2 knots. This was without any forcing, and the stokeholds were not closed up.

The great armoured cruiser Rossia is now in process of completion afloat. She, like the Jeanne d'Arc, is to have three screws, but the speed will be only 19 knots. The boilers are of the Belleville type, and consist of thirty-two generators, of which the total indicated horse-power is 14,500, the grate surface 140·32 square metres, and the heating surface 4378·56 square metres. The boilers are placed back to back, sixteen on each side, in four compartments. Thus the tubes run athwartships. The armament is enormously powerful.

In the United States considerable interest attaches to the laying down of the Kentucky and Kearsage. Their double turrets, the lower part of which is to contain two 13in. guns—described in THE ENGINEER for the 15th instant, and a drawing of whose breech gear was given—and the upper part two 8in. guns, may be a novelty, but they are not a feature that we should like to see reproduced in our own vessels. One happily directed blow from a heavy projectile striking the base of the turret might disable four guns at once. Cofferdams filled with compressed fire-proofed American corn pith cellulose will be worked the entire length of the vessel in the region of the water-line, behind the armour belt, which has a maximum thickness of 16½in., thinning off towards the stern. We should say that these cellulose compartments would have about as much value as those filled with cork in the Inflexible, Colossus, and Edinburgh, which are religiously emptied and refilled with fresh cork periodically, as their contents decay.

A quantity of space is devoted to Japan. And this is not to be wondered at, for, in the course of six or nine months, the Japanese fleet will comprise five battleships—two of 12,450 tons—and armoured cruisers, fourteen large and powerful deck-protected cruisers, and about the same number of torpedo gunboats of large displacement; whilst two battleships and three other cruisers are either building or about to be laid down. In one sense, therefore, it is unfortunate for the Western Powers who retain large squadrons in the China Seas, that the fleet of China should have been so effectually wiped out. Whilst it existed, under the command of the energetic Ting, Japanese ambition was held in check. Now Japan, as a powerful naval Power in the East, has to be reckoned in the light of a possible enemy, and our force in those waters must be greatly reinforced, unless we are to hold our position in Hong Kong and at the Treaty Ports at the pleasure of Japan.

The three following chapters, Nos. III., IV., and V., upon "Relative Strength, and the Navies of France and Italy," we need not say very much about. It is a large order to deal seriously and satisfactorily with the former, and we should be exceedingly sorry to see any desire amongst the authorities of our Admiralty to create a fleet of small second-rate or coast-defence armoured vessels in order to raise our relative strength in this respect. We agree with a recent writer upon this subject, who said that whatever Great Britain possessed in the shape of war vessels should be "first-rate." Chapter IV. is practically an epitome of "La Flotte de Guerre," brought up to date. That on the Italian Navy is an excellent summary of its present position.

Chapter VI., on "Water-tube Boilers," is a short, popular treatise upon the subject; but though it adds very little to what is already well known in regard to the matter, it is well worth perusal. We fully agree with Mr. Dunell, the writer, that much remains to be learned in regard to the lasting qualities of water-tube boilers; and that "whether, with its long and tortuous steam-generating passages, the Belleville boiler will stand forcing, is a point upon which naval engineers will look to have certain evidence before they pin their faith to the type."

Chapter VII., upon the "Naval Gathering at Kiel," points out the fact that it gave us an exceptional opportunity for studying the relative value of features in the latest warships of various naval Powers. This is precisely the view of the event which we should adopt ourselves, and, having done so, we see but little to imitate in such representative ships of foreign navies as took part in the show.

SHORT NOTICES.

Summer Tours in Scotland, by David MacBrayne's Royal Mail Steamers.—This excellent work is too well known to need more than the statement that the 1896 edition is equal in all respects to its predecessors of former years.

A Summer Holiday in Holland. Scheveningen, the Dutch Brighton, and the Interesting Towns in the Neighbourhood. By Chantrey Churchill. Second edition, with illustrations. London: H. Grube, 12A, Paternoster-row. Price 6d.—This is a guide to Scheveningen, with information as to what to see in excursions from that place as a centre. Visitors to Holland for the first time will find a good deal to interest them in this guide.

Mountain, Moor, and Loch. Illustrated by Pen and Pencil, on the Route to the West Highland Railway. With 230 Illustrations from Original Drawings made on the Spot.—Second edition London: Sir Joseph Causton and Sons. 1895. This is just what it pretends to be—an illustrated guide. The artist has in many cases very fairly caught the spirit of the scene illustrated, but no wash drawing can do justice to Luss or Tarbert. The letterpress is very satisfactory. Altogether it is a little book to be recommended to the tourist.

Le Port D'Anvers au XXme Siécle. Alph. Müllender. Liège: Alph. Müllender, 27, Rue des Guillemins.—This is a long thin book giving a very full and statistical account of Antwerp, its growth, dock, wharf, and railway facilities, and great increase in trading prosperity. It shows the tendency of the old city to spread to the opposite side of the river, and brings forward a new project for an underground railway connecting the centre of Antwerp and the proposed new city on the left bank of the river. It is proposed to construct this railway on lines similar to those of the City and South London, illustrations of which are given. The book also describes at length a project for the construction of a new main line connecting the Antwerps by a new bridge, and running almost direct to Düsseldorf *viâ* Moll and other towns north of the present line, which runs *viâ* Liège. The new line will save about 81 kiloms. in the run between Antwerp and Düsseldorf, out of about 380 kiloms., or a saving of about 21 per cent. of the distance. Certain improvements in the river channel are also proposed. Two short bends, for instance, forming a loop are to be replaced by a new curved cut of large radius, and the old channel would form a dock with large quay frontage.

BOOKS RECEIVED.

Crystallography for Beginners, with an Appendix on the Use of the Blowpipe, and the Determination of Common Minerals (after the method of Dr. Albin Weisbach). By C. J. Woodward, B.Sc. London: Simpkin, Marshall, Hamilton, Kent, and Co. 1896.

Metallic Structures: Corrosion and Fouling, and their Prevention. A Practical Aid-book to the Safety of Works in Iron and Steel, and of Ships, and to the Selection of Paints for them. By John Newman, Assoc. M. Inst. C.E., F. Impl. Inst. London: E. and F. N. Spon. 1896.

HORSELESS CARRIAGE NOTES.

DURING last week a new oil motor carriage was kept running about the country round Horley by the makers, Messrs. Roots and Venables, whose vehicle carries two persons, runs on three india-rubber tired wheels, and is not very heavy. It is propelled by a Roots vertical oil engine, using ordinary lamp oil, and with a new form of ignition tube and vaporiser lamp.

THE differences between the results of trials of motor carriages or any self-mover in a confined space and on the long open country ride are so great that the former is useless until supplemented by the latter. Writing us on this subject, Mr. J. H. Knight, Farnham, says:—"It is extremely unsatisfactory to try a motor carriage in a yard. When the machine comes on to the public road many things will crop up which have been overlooked in a trial in a yard only. If any maker of a light motor carriage wishes to make a trial trip with his carriage on a private road and will communicate with me, I can arrange for him to use a private road for a short time. The road is about 460 yards in length, with space to turn at each end. About half the road has a rise of about 1 in 30; the other half is fairly level. The surface is fair. The nearest railway station is about two miles distant." Although horseless carriages are running here and there about the country without hindrance, and it is possible for owners to find a district in which neither the local authorities nor the public are very strongly prejudiced against them, the offer made by Mr. Knight will no doubt be very acceptable to experimenters.

SOCIETY OF ENGINEERS.

RAILWAY BRIDGES FOR BRANCH LINES.

AT a meeting of the Society of Engineers, held at the Roya United Service Institution, Whitehall, on Monday evening, June 1st, Mr. G. Maxwell Lawford, vice-president, in the chair, a paper was read by Mr. M. A. Pollard-Urquhart, M. Inst. C.E., on "Examples of Railway Bridges for Branch Lines."

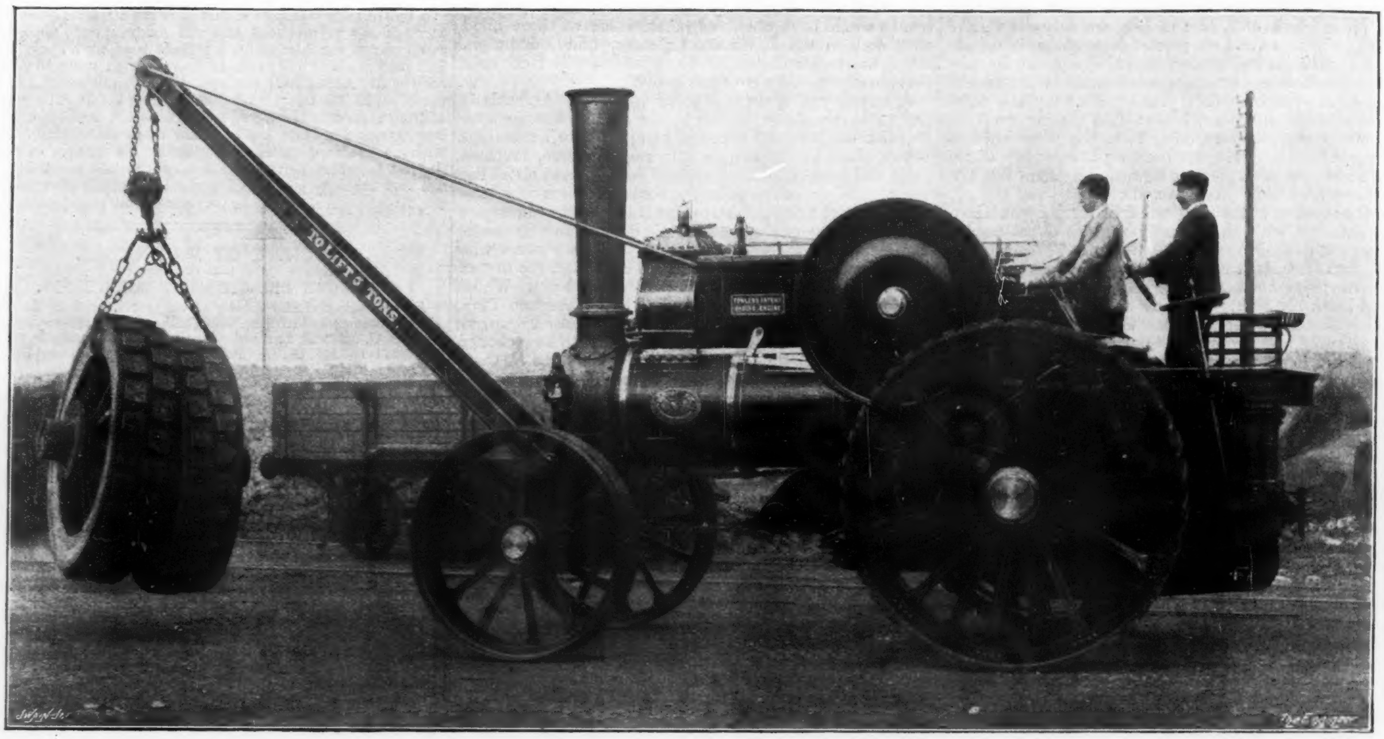
The author first referred to the number and variety of ordinary railway bridges everywhere erected, and proceeded to consider which type was most suitable, as combining economy with efficiency. He pointed out that small branch lines were what chiefly remained to be constructed in this country, and that the bridges under notice were mainly applicable to that class of line. He then drew a comparison between bridges with box wings and those with splayed wings, showing the saving effected by using the latter form. The author then proceeded to show the economy gained by using brick arches instead of girders for bridges carrying roads over the railway, but pointed out that this advantage was chiefly noticeable in single-line bridges, and to a great extent disappeared in double-line structures. The most suitable form of bridge under the railway was then described, and various forms of flooring were referred to. Some examples of bridges for occupation roads were then considered, the author pointing out that when only a small acreage was cut off from a farm, a timber bridge would be sufficient for the moderate traffic that would pass over it. He also alluded to the advantage of using trough girders to carry the railway over small spans, owing to the headway gained. Attention was then drawn to three types of bridges carrying a railway over water-courses, the cost of each of these structures and the time taken in erecting them being given. It was then pointed out that to effect economy, corners and pilasters should be avoided, and the bridge made as simple and easy to build as possible.

NEW INCANDESCENT LAMP.—A new filament for incandescent lamps has been described as made of hygroscopic asbestos paste, which, after being made in sheets ·3 mm. thick, is cut into strips 6 cm. wide, and impregnated with a 30 per cent. solution of platinum chloride. It is then passed through a saturated solution of sal-ammoniac, dried in hot air, and then heated in a Bunsen flame, which converts the platinum solution into a platinum sponge. It is then further impregnated with a 20 per cent. solution of magnesium chloride and heated, which process is repeated until the plate is covered with a uniform coating of magnesia, and it is finally dipped into a 10 per cent. solution of cerite nitrate. The magnesium coating protects the platinum, and as the light-radiating properties of the cerite metals are much greater than those of carbon, the *Electrical Engineer* says it is thought possible that such lamps will take less current.

THE INCORPORATED GAS INSTITUTE.—The thirty-third annual general meeting of the members will be held on Tuesday, Wednesday, and Thursday, June 9th, 10th, and 11th, at the Hall of the Society of Arts, Adelphi, W.C. The chair will be taken by the President, Mr. William R. Chester, M. Inst. C.E. The following programme has been issued:—On Tuesday, June 9th, the chair will be taken at eleven o'clock. Confirmation of minutes of last annual general meeting; appointment of scrutineers to examine the balloting lists for the election of officers, new members, &c.; presentation of annual report of Council; presentation of statement of accounts; presentation of premiums for papers; address by the President. Adjournment for luncheon. Reading and discussion of papers and communications as follows:—"New Details in Gasholder Construction," by E. Lloyd Pease, of Stockton; "Gas Engines as Economical Motors," by J. Holliday, of Scarborough; "A Season's Experience with Incandescent Public Lighting," by F. G. Dexter, of Winchester; "The Popularisation of Gas," by Andrew Dougall, of Tunbridge Wells; "Photometers and Standard Burners," by William Sugg, of Westminster; "Suggestions for a Standard Photometer," by W. J. Dibdin, of London; "The Principles of Transfer of Gas Undertakings from Companies to Local Authorities," by E. Herbert Stevenson, of Westminster; "Letting Gas Apparatus on Hire," by Norton H. Humphrys, of Salisbury. In addition to the above, Professor Frank Clowes, D.Sc., F.I.C., of University College, Nottingham, will on Wednesday, June 10th, deliver a lecture entitled, "Explosive Mixtures of Combustible Gases with Air, and Methods of Detecting and Measuring Minute and Dangerous or Explosive Proportions of such Gases." The annual general meeting of the donors and subscribers to the Benevolent Fund will take place at the close of the sitting, about 5 p.m. It is especially requested that contributors will endeavour to be present. Wednesday, June 10th, the chair will be taken at 10.30 a.m. Reading and discussion of papers and communications. Adjournment for luncheon. Reading and discussion of papers and communications. The sitting will close about 4.30 p.m. Evening: Reception of the members by the President, at the Westminster Town Hall, Caxton-street, Victoria-street, Westminster, at 8 p.m., to be followed by a Conversazione and Dance. Invitations are already in the hands of each member, and it is requested that intimation be sent to the offices, 13, Victoria-street, not later than Wednesday, June 3rd, stating whether it is intended to be present. Evening dress preferred. Thursday, June 11th, the chair will be taken at 10.30 a.m. Reading and discussion of papers and communications. Adjournment for luncheon. Report of the scrutineers; applications for transference; nomination of the President of the Société Technique du Gaz en France as an hon. member; place of next meeting; votes of thanks. Friday, June 12th, Excursion down the Thames, round the Nore Light into Sheerness, and back to London Bridge. 9.30 a m.: Leave Fresh Wharf on board the s.s. Clacton Belle. A tender will start from Westminster Pier at 9 o'clock sharp, calling at Temple Pier at 9.10, and convey the members to the steamer at Fresh Wharf. 12 o'clock: Luncheon on board the Clacton Belle, for all members holding pink tickets. 12.45 p.m.: Luncheon for all members holding white tickets. Members are particularly requested to observe this arrangement, in order that no confusion may arise. Luncheon tickets are transferable amongst those attending the trip, to allow of friends lunching together if desired. 1.30 p.m.: Arrive at Sheerness. Through the courtesy of the captain-superintendent, a pass has been furnished to the Chief Inspector of Police, which will allow members to view the Sheerness Dockyard and Flagship. The Clacton Belle will moor at the pier about 1.30, and members will be conducted round the Dockyard, which is situate about ten minutes' walk from the pier. 3 p.m.: Leave Sheerness. 5 p.m.: The Clacton Belle will call at Gravesend to disembark any members preferring to complete the journey by rail. 6.30 p.m.: Arrive at London Bridge.

COMPOUND ROAD LOCOMOTIVE WITH CRANE

MESSRS J. FOWLER AND CO., LEEDS, ENGINEERS



THE BATH AND WEST OF ENGLAND AGRICULTURAL SHOW.

As promised in the brief notice of this show which we gave last week, we are now enabled to place before our readers full particulars and an illustration—Fig. 1—of the 10-horse power compound road locomotive fitted with crane which Messrs. John Fowler and Co., Leeds, had on view. The leading dimensions of this engine are as follows:—Cylinders, 6¾in. and 11½in. diameter by 12in. stroke; fly-wheel, 4ft. 6in. diameter by 6in. wide; driving wheels, 7ft. diameter by 20in. wide; front wheels, 5ft. diameter by 16in. wide; capacity of water tank, 220 galls.; and capacity of coal bunker, 8 cwt. It is mounted on spring gear having strong locomotive type plate springs under the hind axle, with compensating levers, so arranged that they regulate the motion of the engine always at right angles to the axle, thus obviating any cross action on the spur gearing. The hind axle and third motion shaft-bearings slide in hornblocks, allowing a vertical movement of 2in. The road spur pinion is actuated by a driving frame from the third motion wheel in such a manner as to keep the pitch circles of the two wheels always in contact. The jib crane is designed to lift five tons. It is operated by bevel gear and worm and worm wheel, while the front road wheels of the engine are made of extra width to allow of the carriage of a load on the crane. The cylinders are steam jacketed, the valve chest being placed between them, while to allow of the cylinders being worked together for convenience at starting, a valve operated from the foot-plate, and designed to close automatically, is provided. The slide valve excentrics are cast together and secured on the crank shaft by one large key. The crank shaft and axles are of hammered steel, and carried in malleable iron brackets fitted with gun-metal brasses, the bearings being let into recesses formed in the fire-box shell side plates, which are extended to receive them. The gearing is of crucible cast steel, arranged as far as practicable to work inside the crank-box, and the road motion is designed for two speeds, while the crane gear is placed within convenient reach of the driver, who has thus the power to work the crane both hoisting and lowering. The boiler, made of mild steel plates having the rivet holes drilled *in situ*, is constructed to withstand a pressure of 180 lb. per square inch. The smoke-box is flanged inwards at the front end, and welded at the joint, square corners subject to corrosion being thus avoided. The road wheels are built up of strong tee-iron rings, wrought iron forged spokes, and cast iron bosses, the driving wheels being shod with diagonal cross bars, and having also a number of bolt holes drilled in the rim for affixing a wooden ring or blocks to give additional adhesion, while the front wheels are provided with steel lapping plates. The driving wheels are also fitted with a powerful hand brake, the blocks of which bear upon the inner surfaces of the rims. As will be seen from the illustration, this brake is operated by the driver by means of a hand-wheel and screw.

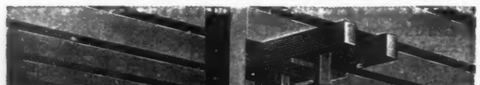


Fig. 2—CARTER'S PENDULUM SIFTER

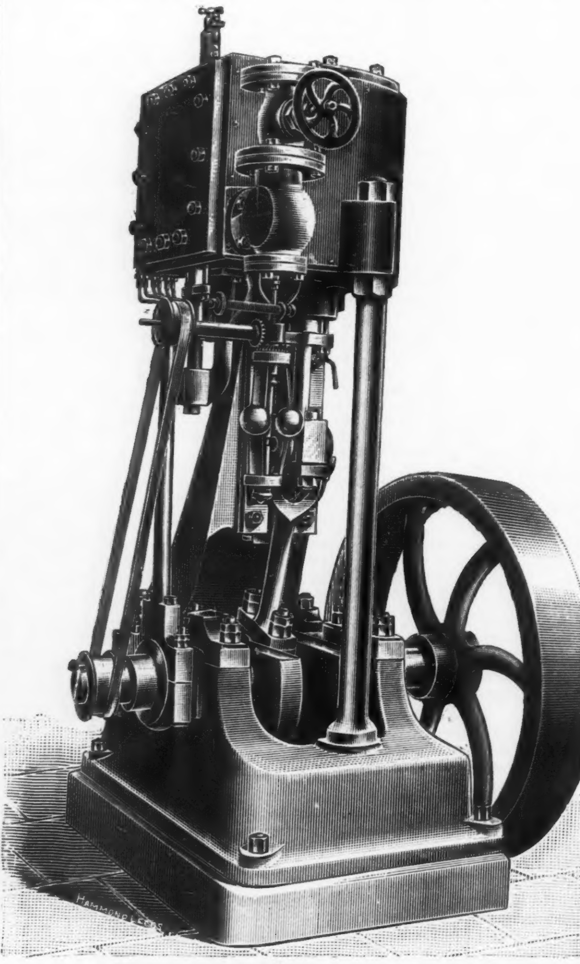

Fig. 4—EASTON AND BESSEMER'S HIGH-SPEED ENGINES

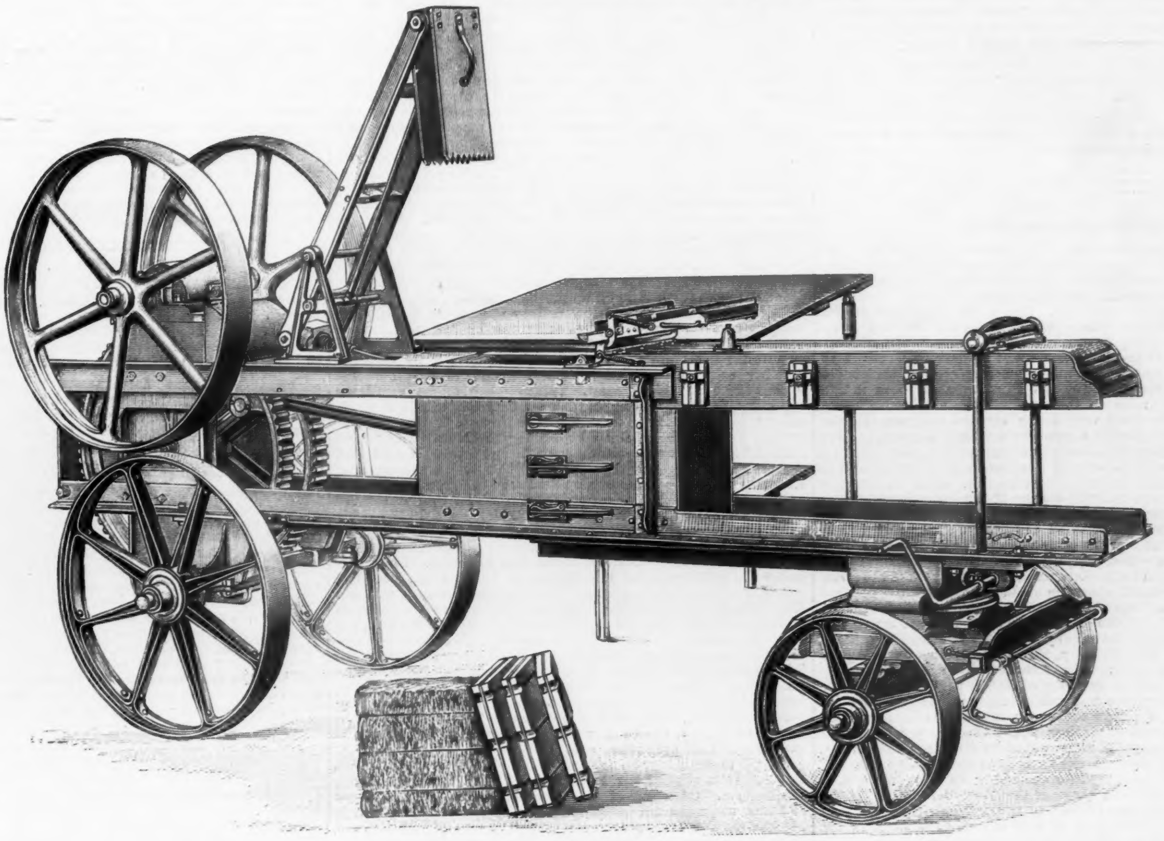
Fig. 2, this page, represents a device called a loose silk pendulum plane sifter, although the loose sifting material is not a plane—for scalping, grading, and dressing flour. This appliance was exhibited by Mr. J. Harrison Carter, of Dunstable, and is said to give better flour while occupying less floor space, and consuming less power than the ordinary centrifugal dressing machine. The pendulum, which is really the body of the machine, is composed of a series of sieves placed one above the other, and the feed entering at the top passes over each of the sieves till the overtails leave at the bottom. The flour—separated from each sieving—falls on to a canvas fixed tightly over the silk of the next lower sieve, and is then by the pendulum or gyratory movement conveyed to openings through which it falls to the tray at the bottom. Thus the flour at the bottom is taken off at the same sleeve. The pendulum is suspended from one point only, a universal ball bearing in the centre of the machine, by which the weight is taken. By the excentric motion of the crank from underneath, its axle moves in the mantle of a cone, and the sieves incline alternately in every direction, thus imitating the hand sieve movement. By securing the silks loosely over the frames, folds or undulatory waves of the fabric are produced by the gyratory movement, and the material being sifted keeps these undulations in constant movement. It is claimed that this feature obviates the necessity of a cleaning device for the silks. The floor space required by this machine is 3ft. 6in. by 3ft. 3in., and the head room 8ft. 6in., while the speed found to give the best results is 175 revolutions per minute. Mr. Carter also exhibits a new wheat heater and steamer for conditioning the grain before grinding. This apparatus consists of two wrought iron concentric cylinders with conical top. In the annular space between these cylinders numerous

SELF-FILLING PERPETUAL BALING PRESS

MESSRS. J. AND F. HOWARD, BEDFORD, ENGINEERS



coils of steam piping are arranged over which the grain passes, its speed being regulated by means of a valve. Steam cocks are fitted at the inlet and outlet ends of the coil, and a third cock fixed on the top of the machine allows the steam to be admitted in direct contact with the wheat. Messrs. Edward Humphries and Co., Atlas Works, Pershore, exhibited portable engines and thrashing machinery, all of which were of their well-known standard patterns.

Our illustration above, Fig. 3, represents a baling press for hay and straw with a new self-feeding arrangement and automatic hinged dropper, made by Messrs. J. and F. Howard, of Bedford. The general arrangement of the machine will be familiar to most readers, who will also be aware of the danger which the operator was formerly exposed to in the old-fashioned hand-fed apparatus. The feed arm, shown in an oblique position in the engraving, is elastically connected to the gearing which drives the ram, so that as the ram is being withdrawn to the end of its travel the feeder arm descends and carries with it the hay or straw into the baling chamber, and whilst the ram advances the feeding arm rises clear above the press. The workman standing at the side of the press has only to push the hay or straw over the open chamber and to place a follower in the dropper frame whilst turned back. The frame then being raised, the feeder arm in descending releases the follower and guides it into position ready for the ram to push it past the retainers. With a 4 or 5-horse power engine a pressure of 25 lb. per cubic foot can be obtained on the material being baled.

Messrs. Christy and Norris, Chelmsford, exhibited their disintegrators, in which improved corrugated sides have been provided. It is stated that these corrugations keep the material under treatment more in the path of the beaters than those formerly employed. This firm is also fitting self-lubricating bearings of the ring type, as successfully used on dynamos, on these machines. On Messrs. Clayton and Shuttleworth's stand a Hett centrifugal pump was at work, being driven by this firm's portable oil engine with a new ignition device. Mr. James Coultas, of Grantham, showed an improved corn drill, in which, by means of a worm and worm-wheel device on the coulter bar stay, the coulters can be moved to any desired angle. Amongst a miscellaneous exhibit Messrs. Easton and Bessemer, Limited, Taunton, showed a well-designed 20-brake horse-power vertical high-speed steam engine, Fig. 4, specially constructed for electric lighting purposes, in which special attention has been given to very accurate balancing of the moving parts. Being very compact, these engines are specially suitable for ship lighting, where space is limited. They are fitted with the well-known Pickering governor, which admits of the speed being altered whilst the engine is running. The lubrication of the working parts is automatic, the necessary quantity of oil being distributed from a common source to each working part through copper pipes. The engine is constructed for a working pressure of 80 lb., and its leading particulars are:—Cylinder, 8½in. diameter by 8in. stroke; diameter of fly-wheel, 3ft. 4in.; extreme height of engine, 5ft.; floor space occupied, 3ft. 11in. by 3ft. 1in.; revolutions per minute, 300; and weight, 1½ tons.

Messrs. Harrison, McGregor, and Co., Limited, Leigh, Lancashire, had a very important exhibit of mowers and reapers, including one of new design with changeable speed gear, which is so arranged that either a fast or slow movement of the knife can be effected by the driver from his seat to suit the material being cut. Messrs. F. C. Southwell and Co., Upper Thames-street, London, showed, amongst other implements, an improved two-horse binder manufactured by the well-known Deering Harvester Company of Chicago, U.S., fitted throughout with hard steel ball and roller bearings. Messrs. G. H. Innes and Co., Hitchin, had on view at their stand an improved lifting attachment for "Bedfordshire" seed drills, by which arrangement the laborious process of lifting the drill by manual labour when turning at the land's end is entirely avoided. The apparatus is extremely simple in action; by simply lifting a lever the drill is raised ready for turning, the lever automatically locking itself in an upright position, leaving the man free to guide the drill in turning, while by again pulling back the lever the drill is instantly lowered ready for work. This attachment is made so that it can be fixed to any existing drill of the "Bedfordshire" type.

Messrs. Sargeant and Co., Northampton, had on view an improved manure distributor, with new reciprocating scraper fitted inside the box, whereby the manure is prevented from "caking" on the chains and clogging up the exits. This scraper is actuated by a cam device from the hub of the wheel, and, being provided with raised bosses along its upper surface, raises and lowers the chains with the object above alluded to.

HORIZONTAL AND VERTICAL MILLING MACHINES.

THE universal horizontal milling machine illustrated on page 568, will in addition to all the ordinary forms of straight milling of which these machines are capable, form the teeth of milling cutters, wheels, reamers, &c., and the flutes of twist drills, taps, and other useful workshop tools. It is a strong and very powerful machine, especially suitable for marine engineering work, and will mill flat surfaces up to 6in. or 8in. wide and 2ft. 6in. long, and when working, a cutter 4in. diameter will admit a maximum depth between it and the table of 14in. Cuts may be taken exceeding ½in. in depth, and the speeds of the "feed" traverse are graduated from under ½in. per minute to a rate exceeding 2in. The fast headstock has double gearing — the wheels being all machine cut—and a four-speed cone pulley, the steps being respectively 13in., 11in. 9in., and 7in. diameter, and 3in. wide. The overhanging arm carrying the outer support for the cutter arbor is cast in one with the headstock, thereby affording great rigidity. The main spindle is of steel, 3in. diameter, carried in hard gun-metal adjustable bearings, so arranged that the "cutting" thrust is against the solid metal. The feed mechanism is carried directly through the centre, around which the table swivels, and serves without alteration for all the varying positions—vertically, angularly, or horizontally—in which the table may be placed. The accessories provided with the machine, which form a very complete set, are clearly shown in the engraving, and are accompanied by a printed tabular form setting forth at a glance the various angular positions and divisions required for the multiplicity of work this truly "universal" machine is destined to cope with.

Our second illustration shows a patent self-acting vertical milling and profiling machine, used chiefly for edge milling, but it is also very efficient for machining flat surfaces. The latter are operated upon by means of "face" cutters, which are made with inserted teeth, when dealing with large surfaces, and are specially applicable for marine engineering work. The machine is very rigidly constructed, with a hollow frame of the slotting machine type, as shown in the illustration, which is taken from a machine measuring 2ft. 2in. from the centre of the spindle to the frame, and 1ft. 9in. from spindle nose to table top—maximum. The spindle is of steel with conical bearings having a diameter of 3½in. at the main neck, and it runs within a 6½in. square bar forming a vertical slide, and rising and falling with it, so as to keep the bearing always close to its work, and give great solidity of action. This bar has a vertical motion of 12in., and is balanced. The table is rectangular, measuring 3ft. 6in. by 2ft. 3in., with tee grooves for securing work, and a trough all round for collecting the lubricant. It is provided with variable self-acting motions, longitudinally, transversely, and circularly, all being reversible; and the circular motion can be readily disengaged to facilitate the rapid concentric setting of the work on the table. When profiling, the longitudinal table slide is disengaged from the screw, and the "former" or model is fixed on the table, directly underneath or alongside the object to be formed, and is held against an adjustable roller, carried by a swinging bracket attached to the main frame of the machine. This attachment is not shown in the illustration. The traverse of the table is 2ft. longitudinally and 3ft. transversely. The rates of feed traverse range from about ½in. per minute to over 2in., and cutters up to 8in. or 10in. in length may be used, in such cases a special support being arranged for the cutter arbor at its lower extremity. A centrifugal pump and the requisite fittings for lubrication are provided, the supply being drawn from a suitable tank formed in the frame of the machine. The driving motions are transmitted from a cone pulley with ample belt surface, through powerful gearing, the teeth of which are all machine cut, and without the intervention of any sliding keys.

THE BLACKWALL TUNNEL.

THIS great undertaking was thrown open to the public on Whitsun Day and Monday for a temporary view. On November 2nd and 3rd it was also shown, and those who availed themselves of Messrs. Pearson and Son's liberality upon both occasions can judge pretty well of the great progress made towards completion. The portion under the river is now quite free from the huge bulkheads which formerly divided it into three sections, and is apparently ready to receive its lining of white glazed bricks. The loose timbers and movable plant of various kinds which made the passage through a matter requiring considerable care are mostly removed, and nothing obstructs the footway save the wooden rollers over which runs the rope for drawing out the earth-laden trucks. Although the portion now excavating is the northern approach, the spoil is led through the tunnel and taken up No. 3 shaft or caisson on the south side. On that side the tunnel itself, and the open part of the cutting leading to it, were bricked and virtually finished some months ago. The entrance is about a mile below Greenwich Hospital, in the flat and cheerless region known under the poetical name of Bugsby's Marshes. A large wooden shed about, over the tunnel, and close to the water's edge on the Greenwich or Kentish shore, contains the boilers and engines of the air-compressing and electric-lighting plant. Close to this shed a temporary steamboat pier was erected for the holidays, and the weather being extremely fine both days, a great many people availed themselves of it. The tunnel is very dry on the whole, though, of course, there are slight "weeps" here and there, which will disappear when the edges of the segments are finally caulked with iron borings and made right and tight. No damp feeling is perceptible in the air, and the atmosphere is remarkably clear and pleasant. Under the river, about 400 yards, the tunnel is quite straight, but going from south to north a slight turn to the left takes place just before going under the water. When we visited the works in November the great shield lay like a stranded whale at the bottom of No. 2 shaft, the one at the water's edge on the Middlesex side having just completed its journey through. Very curious it looked, too, festooned all over with small incandescent lights, and its dark sides glistening with the rain which fell steadily down the shaft. Now it is invisible to strangers, being well on its way up the gradual slope, which will be finished by "cut and cover" and finally come to the surface near the Poplar station of the Great Eastern Railway. Air pressure is still being used, the ground being shingle or Thames ballast full of water. In consequence of this there is a solid brickwork bulkhead just outside the

No. 2 shaft in the rear of the shield, provided with air locks opening into the shaft. Two or three small round windows or peep-holes of thick glass are provided that the proceedings within may be kept under observation. The shield itself is, as is well known, on the Greathead system, with several additions and improvements by Messrs. Pearson and Son, the contractors. It is 27ft. 9¼in. in external diameter, 19ft. 6in. long, and weighs 220 tons. There are twelve working cells in its face, and it is considerably the largest in diameter that has yet been used in such work. Not a single death or any case of serious injury from the use of compressed air has yet taken place, but in this respect, of course, the experience of similar works has been of much service. The tunnel will be quite finished and open to the public, both for foot and vehicular traffic, in a few months.

AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

Locomotive and cable traction.—The elevated railways and the electric tramways of Brooklyn have begun negotiations for running through cars and through trains over the Brooklyn Bridge to New York, to avoid the present inconvenient transfer from and to the cable railway trains of the bridge. One of the difficulties in the running of the elevated railway trains would be the very steep grades, which are nearly 4 per cent., and the present steam locomotives used with these trains would not be powerful enough to haul the five-car trains. It was at first suggested that more powerful locomotives, with the weight distributed so as not to impose too severe strains on the structure, should be built, but this would have involved very heavy expense and considerable delay. A more practicable suggestion was that a special power grip should be put on the elevated railway engines, to consist of a modification of the cable-car grip, adapted to train service and to the special features of the bridge construction. Such an arrangement would involve no material change of the cable-driving plant of the bridge as now established. With this grip in position, the engine coming from the elevated railway on either side of the bridge would run out over the cable at about the same speed with it—ten miles an hour—and gripping the cable firmly without injury to it, the train would be hauled over to the other side of the river, where the engine would release its hold on the cable and proceed under its own steam over either of the elevated roads. There has been some trouble with the present grip on the bridge because of the difficulty of setting it firmly by hand. The new grip, though, would present no such difficulty, since the power of the engine could be utilised to set it. It is estimated that with such a traffic arrangement, a carrying capacity of 50,000 passengers an hour over the bridge is within reasonable limits, provided the entire system of trains is placed under one management. Any overcrowding at the terminal stations would then be practically impossible, since the elevated railway stations on either side of the river would be somewhat removed from the bridge terminal stations, the latter being used for passengers reaching the bridge by other approaches than those of the elevated railway. If the electric railways are also allowed to run through cars, a single track will probably be laid on each of the carriage ways of the bridge. At present the cable trains of four cars—weighing 20 tons each, empty—are run at intervals of 1½ minutes, but are entirely unable to deal with the enormous crowds during the rush hours of the morning and evening.

New navy dry docks.—Two new dry docks have recently been completed for the United States Navy, one at Port Royal, on the Atlantic, and the other at Port Orchard, Washington, on the Pacific Coast. The latter dock is on Puget Sound, near Seattle, and was formally opened in April by the entrance of the monitor Monterey. The dock is 650ft. 5in. long between end copings and 573ft. 7in. long on the floor, while the width at the middle is 130ft. 1in. between copings and 67ft. 1in. on the floor. The entrance lock has a width of 92ft. 8in. between copings. The depth from coping to floor is 39ft. 3in., while the depth of water at high-water level is 30ft. on the entrance sill and 28ft. 2in. on the keel blocks. The construction is of timber, as used so successfully in the Simpson docks at other navy yards. The vertical and diagonal piles, sheet piling, and altar brace timbers and altars are heavily braced, and the floor is covered with 3ft. of concrete. The entrance lock is of sandstone and granite, and is closed by a steel caisson, 96ft. long, 25ft. wide, and 39ft. deep. In this caisson are a pumping engine, boiler, and steam capstan; while its sixteen valves, 20in. diameter, are operated by hand wheels on the main deck. The pumping plant for the dock consists of three 42in. centrifugal pumps, each with a capacity of 110,000 gallons per minute, driven by vertical engines with cylinders of 24in. stroke. Steam is supplied by six tubular boilers, externally fired, carrying 150 lb. steam pressure. As the dock contains 14,000,000 gallons when full, it can be emptied in about two hours if necessary. The Navy Department has now ten completed dry docks for large warships, as follows:—

Location.	Material.	Length, feet.	Width floor, feet.	Water, ft.	in.
Boston	Stone	391	30	27	0
Brooklyn	Stone	350	30	25	6
Brooklyn	Timber	530	50	25	6
League Island	Timber	530	50	25	6
Norfolk	Stone	360	30	24	0
Norfolk	Timber	530	50	25	6
Port Royal	Timber	600	50	26	0
Port Orchard	Timber	650	50	26	0
Mare Island	Stone	530	30	28	0

A great suspension bridge.—Work will soon be commenced on the new suspension bridge over the East River to connect New York and Brooklyn. The present bridge, opened in 1883, is greatly overtaxed, in spite of the numerous large steam ferries, and it is hoped to finish the new structure in about four years. It will have a clear span of 1605ft.—10ft. more than the present bridge—and a clear leadway of 135ft. at the middle, and 117ft. at the towers. The width will be 118ft., having two roadways, two foot walks, two tracks for the trains of the elevated railways—which will build connections to the bridge—and four tracks for electric tram cars. The foundations will be sunk by pneumatic caissons of timber, the depth to bed rock being about 60ft. below high water on the New York side, and 80ft. on the Brooklyn side. The masonry of the piers will extend to about 20ft. above the water, and on this will be steel towers rising to a height of 340ft. above the water. The stiffening trusses will be of considerable depth. The shore spans will be formed by continuations of these trusses, resting on the towers and anchorages, and supported by intermediate piers, forming a viaduct, but these spans will not be supported by vertical cables from the shore ends of the main cables. The new terminal stations of the cable railway over the existing bridge are approaching completion and are expected to relieve the overcrowding of the trains, while electric motors on one car of each train are to be used for switching the train at the terminals, thus doing away with the present steam switching or shunting engines. A third bridge over the river is now also under construction, this being some distance further up, where Blackwell's Island affords an opportunity for placing two piers of the great cantilever trusses, which will span the two navigable channels. This bridge is for the Long Island Railroad.

Railway ditching machine.—The Doddridge ditching machine, built for the St. Louis South-Western Railway, is intended specially for use on railways in damp and swampy districts where it is important to keep open good ditches to drain the ballast roadbed. It is a large flat car 46ft. long, carried on two four-wheeled trucks or bogies. It is constructed of longitudinal plate girder sills fastened and braced with angle irons of suitable sizes. To these are fastened the end sills, which are heavy steel castings, and have extended curved ends to receive the chains used in connection with the beams for pulling the plough, scraper, &c. All the machinery and tools used in connection with the ditcher are operated by compressed air, the reservoirs underneath the car carrying a pressure of 80 lb., which is supplied by the air pump on the locomotive used to move the machine. On the car is a steel derrick centrally located, 9ft. high, having a reach of 14ft., and being so arranged that it can describe a complete circle. The tools used in connection with the car are as follows:—A solid cast steel plough weighing 2500 lb., which cuts a furrow 20in. deep by 36in. wide; a triangular shaped scraper, an embankment former, and a scoop excavator of three cubic yards capacity. All of these tools when in use are operated by air from the platform of the car by cocks arranged on a switchboard. Underneath the car are located the air cylinders, which are as follows:—Three reservoirs 22in. in diameter and 10ft. long, which contain the air supply; one cylinder for the derrick hoist, which is 12in. in diameter by 14ft. 7in. long; one cylinder for swinging the derrick, which is 12in. in diameter by 9ft. 5in. long—the piston of this cylinder is arranged with a rack attachment for swinging the mast in a complete circle—four side guide cylinders 8in. in diameter, by 5ft. 4½in. long. All cylinder pistons are air cushioned, taking air from either end. Each tool when in use is slung from the derrick or jib, which regulates its height, chains are led from the corner of the car to the front of the plough, &c., while side braces and the guide cylinders regulate the lateral position. The plough loosens the earth, the scraper draws the loose earth in to fill up the embankment, and the template of the former trims off the earth to the proper slope. The scoop is used for digging and cleaning out the ditches.

Sand cement.—A plant has recently been put in operation for the manufacture of "sand cement," which is formed by grinding together to an impalpable powder a good grade of Portland cement and a clean sharp sand. This not only secures the advantages due to fine grinding of the cement, but effects a much closer and more uniform combination or mixture of the sand and cement than can be obtained by ordinary methods. The "sand cement" is used as a substitute for ordinary Portland cement, and is mixed with unground sand for use. The tensile and crushing strengths are very satisfactory, and material has been largely used in the massive monolithic concrete foundations for the Cathedral of St. John the Divine, in New York, including some 13,000 cubic yards of concrete. The sand and cement are thrown into hoppers with a spout, in which is a measuring device which can be regulated to pass any desired proportions of the two materials. From this meter the mixture is fed into horizontal boiler iron cylindrical grinding mills, which revolve on their longitudinal axes, and are filled with hard flint pebbles. The churning of the revolving mass by these pebbles grinds the sand fine and incorporates it completely with the cement. The cylinders are 4ft. 2in. diameter and 18ft. 9in. long, making twenty-six revolutions per minute. The interior is lined with special glazed bricks laid in cement. The proportions of the mixture are generally one of sand to one of cement, but for special purposes one to six is used. Plain sharp sea sand is used. The finished product, or "sand cement," is so fine as to leave a residuum of only 5 per cent. on a sieve of 180 meshes, or 32,000 per square inch.

United States Navy.—The first trial of the new battleship Massachusetts showed her to be at least equal to her sister-ship the Indiana. On a run of thirty-five hours she averaged over 13 knots, while the maximum speed under natural draught was 14¾ knots. The engines averaged 102 revolutions per minute, and their maximum was 111 revolutions. The Massachusetts averaged 13½ knots at 103¾ revolutions, and a slip of 18 per cent. for the screws. The Indiana on her first trial averaged 13 knots at 103 revolutions, and a slip of 24 per cent. The former made 15·6 knots average, and 15·9 knots maximum on the speed trial, while the contract speed was 15 knots; this was with 125 to 129 revolutions. The Secretary of the Navy has decided in favour of double or superimposed turrets for the two new battleships Kearsarge and Kentucky, which are soon to be contracted for. The plan was so warmly advocated, and so strongly opposed, that special investigations were made. After the Board of Construction had opposed it by a vote of four to one, the Secretary appointed a special board of seven officers, to each of whom were submitted the lengthy written arguments for and against the plan, including those of the chiefs of the Bureaus of Construction and Ordnance, who had respectively opposed and favoured the plan. Five of these officers reported favourably and two adversely, and after due consideration the Secretary decided to adopt the double turret plan for the following reasons:—(1) It permits a better horizontal range of fire. (2) It gives much better protection to the 8in. guns in the upper turret. (3) It permits the establishment of a superior rapid-fire battery. (4) It gives a heavier fire in every direction. (5) It saves the cost and weight of four 8in. gun turrets, with armour, substructures, turning engines, &c., the saving being about 248,000 dols., while the total weight of the double turret emplacement is about 200 tons less than is that of a single emplacement for a 13in. gun. (6) The one valid objection is that if the turning gear of the large turret is disabled it will stop the rotation of four guns, but as this gear is protected by the best armour in the ship, the chances of its injury are reduced to a minimum.

A large railway terminal and port.—The great terminal establishment of the Chesapeake and Ohio Railway at Newport News, near Norfolk, includes a passenger pier, two coal piers, four freight and merchandise piers, a grain elevator of 1,500,000 bushels capacity, and several storage warehouses, located on land owned by the company, with water frontage of 4500ft., extending back 3000ft. The depth of water at piers averages 25ft. to 30ft., and each pier is equipped with well arranged yards, the tracks aggregating 30 miles in length, and having storage capacity for 3000 cars. The eastern entrance extensive receiving yards are located for the reception of incoming trains, and from these the freight cars are drilled to the pier to which they are consigned without interfering with the operations of the main line or of any of the other auxiliary yards. Double passenger tracks enter the yard at the westerly side of the freight yards and piers, extending to the end of the passenger pier No. 1, enabling passengers to remain under cover in passing to and from the company's steamer for Norfolk. The passenger pier and double-deck merchandise pier were built within the last four years. The others have been overhauled, painted, and otherwise put in first-class condition. All are lighted by electricity, and thoroughly equipped with apparatus for fire protection. The passenger station is a three-storey structure located at the shore end of the pier, and has comfortable and convenient arrangements for passengers, with separate provisions for emigrants. The upper floors are used as offices for the Superintendent of Terminals and other local officers of the railway. Piers Nos. 2 and 3 are coal piers, and are 700ft. and 1000ft. long respectively, equipped with two dumping tracks and one return track each. The tracks are arranged on the "gravity" plan, making it unnecessary for locomotives to go upon the piers. The receiving tracks for the loaded cars are on a plane about 20ft. above the lower or empty car tracks. Loaded cars are moved over the upper deck by gravity, passing over the scales, and, when unloaded, run by gravity to the end of the pier, operating trick switches, and return on the lower track to the "empty" car yard, where they are inspected, repairs made, and air-brakes tested before sent out in trains. The two piers have a capacity of about 8000 tons per day. Pier No. 4 is a double-deck merchandise pier, 160ft. wide by 600ft. long having a floor area on the upper deck of 79,000 square feet, and on the lower of 65,000 square feet, with two tracks connected with the yard assigned to it. Vessels can be loaded from either of the decks. The pier is equipped with six automatic elevators, with a capacity of handling from 600 to 700 packages per hour each; two are large enough to take up hogsheads of tobacco. Pier No. 5 is a single deck merchandise pier, 150ft. by 800ft., having a floor area of 82,000 square feet, with two tracks connected with the yard assigned to it. This pier supports on each side an overhead belt way, along which the grain from the elevator is moved, and deposits in the vessel by adjustable down chutes spaced 50ft. apart on each side of the pier. Pier No. 6 is a single-deck merchandise pier 140ft. by 700ft., having a floor area of 61,000 square feet; two tracks connected with the yard assigned to it. Pier No. 7 is a smaller merchandise pier, used for handling staves, ice, &c., and for loading schooners and other small craft. The substructure of all the piers at the port consists of piles creosoted with 16 lb. of dead oil to the cubic foot of timber, to protect them against the ravages of the teredo. A transfer bridge for the transferring of freight cars to and from car floats plying between the port and Norfolk or Portsmouth is located between piers Nos. 6 and 7. The grain elevator stands inland to the rear of pier No. 5. Two unloading tracks, the entire length of the elevator, connect it with the yard assigned to this business. The grain is conveyed to pier No. 5 by belts. The capacity is 300 cars in and out per day. The water is supplied from the city waterworks. These works are some sixteen miles from Newport News, and the main leading to the town is laid along the right-of-way of the Chesapeake and Ohio Railway. A branch railway ten miles in length extends from Newport News to Old Point Comfort—at Fort Monroe—which is the passenger terminus of the line.

A MILLION DOLLARS FOR NEW WATER MAINS IN NEW YORK CITY is authorised by a legislative statute just signed by Governor Morton. It is said that the Bill provides for two mains down Fifth Avenue. At present eight 48in. mains lead down into the city from the new aqueduct, four going to the Central Park reservoir and four connecting with the distributing mains.

THE INCORPORATED ASSOCIATION OF MUNICIPAL AND COUNTY ENGINEERS.—The Midland Counties District Meeting will be held at Hanley on Saturday, June 13th, 1896. The following programme has been issued:—11.30 a.m., meet at Town Hall; reception by the Mayor (Mr. Councillor Tunnicliffe); paper by Joseph Lobley, M. Inst. C.E., borough engineer and surveyor of Hanley, entitled, "Some of the Public Works carried out in Hanley during the last Ten Years;" discussion. 12.15 p.m., inspect Quarter Sessions Court and Victoria Hall, where light refreshments will be provided by his Worship the Mayor, the Chairman of General Purposes Committee (Mr. Alderman Shirley) and the Chairman of the Works Committee (Mr. Alderman Ridgway). 12.30 p.m., short organ recital by Mr. G. Barlow, borough accountant; after which the members will proceed to view:—12.45 p.m., free library and boys' reading room, technical museum; 1.10 p.m., markets and sub-stations; 1.30 p.m., higher grade school; 2 p.m., the electricity works; 3 p.m., Hanley Park—in course of formation—bridges, lodges, pavilion, terraces, lake, conservatory, &c.; 3.30 p.m., sewage works: inspect sludge presses and Bacillite Sewage Purification Syndicate's experimental works; 4 p.m., Stoke-road electric light cable laying, sub-stations and street improvement; 5 p.m., tea at North Stafford Hotel, near Stoke Station, 2s. each.

THE SECOND BAVARIAN NATIONAL EXHIBITION IN NURNBERG.—For the second time an exhibition of the products of manufacturing industry and the fine arts has been organised by a committee of the Gewerbe Museum—which may probably be rendered as the Bavarian equivalent of South Kensington—to be held in the Municipal Park at Nürnberg. Following the example of its predecessor, the present exhibition is confined to objects originating in Bavaria, and therefore affords a very favourable opportunity for studying the industrial condition of that very active little country. To some extent the division is geographical, the objects being classed according to provinces, but this arrangement does not, of course, apply to the large exhibits and those requiring motive power, which are brought together in a single building. The total area covered by buildings is nearly forty acres; and although a large part of this is devoted to accessory purposes, the main buildings, including those of the railway and education departments and the machinery hall, take up about a quarter of the whole. Among the special features may be mentioned a full display of the supply of the smaller industries for which Nürnberg and the surrounding district are famous—such as toys, optical goods, bronze and tinsel, steatite burners, &c, which are shown in connection with electrical and other small motors. In the larger subjects brewing is well represented, as is also high-speed printing machines, both being Bavarian specialities. In the machinery hall, a three-aisled building, measuring 500ft. by 200ft., and 60ft. high, the leading steam engine makers of the country, including the Nürnberg Joint Stock Company, Messrs. Sulzer, Durgler, and others, contribute examples, both for dynamo and ordinary mill driving, to a total of nearly 3000-horse power. The exhibition will be open from May 15th to October 15th. Those who remember the extremely high quality of the display of 1882 will no doubt be glad to revive their recollections by a comparison with that made on the present occasion should the opportunity occur, and such an opportunity will be readily found by those who intend to visit Buda Pesth, when Nürnberg may be taken as an agreeable break on the road, either coming or going.

ADDITION TO THE AUSTRIA-HUNGARY NAVY.—The principal dimensions of the new coast defence battleship Buda-Pest, launched recently from the Stabilimento Tecnico Triestino at San Rocco, near Trieste, are as follows:—Length, 303ft. 6in.; beam, 55ft. 3in.; displacement, 5550 tons; mean draught, 20ft. 6in. The hull of the ship is constructed of Siemens-Martin steel; divided into the usual cellular and water-tight compartments, while the pumps will be sufficiently powerful to discharge 1500 tons of water hourly in case of necessity. Protection is afforded by an armour belt of 10·8in. nickel steel, made by the Austrian firm of Witkowitz and Co., tapering to 8in. aft and 5in. forward, which runs from the ram for five-sixths the length of the ship, extending from 3ft. 6in. below to 3ft. 6in. above the water-line at normal draught; the after ends being joined by an 8in. armoured-athwartships bulkhead. On the top of the belt runs fore and aft the whole length of the ship a 1·8in. armoured deck, rising above which, and extending from the after end of the armoured belt for about two-thirds of the ship forward, is a citadel protected with 3·3in. armour, with transverse bulkheads of the same thickness of plating. Above, again on the upper deck, is a smaller citadel, also protected with 3·3in. armour, fore and abaft which, but with their bases protected by the armoured lower citadel, are the two barbettes for the heavy guns, plated with 8in. armour, and fitted with 2·5in. steel hoods for the guns. There are further two conning towers, the foremost with 8in. plating, the after with 2·5in. The whole weight of the armour amounts to 1700 tons. The armament consists of four 24 cm. (9·4in.) 40 calibre long Krupp guns, mounted in pairs in the barbettes. Each gun weighs 26 tons, and the mountings for each pair of guns, including the hood, 123 tons. The armour-piercing projectile, which weighs 474 lb., has an initial velocity of 2275ft., and, with an elevation of 25 deg., has a range of 16 kiloms. (10 miles). The secondary battery consists of six 15 cm. (5·8in) quick-firing guns, two 7 cm. Uchatius guns for boat and landing purposes, sixteen 3-pounder quick-firing guns, and two mitrailleuses with two broadside torpedo tubes. The six 15 cm. quick-firing guns are mounted in the citadel on the upper deck, two firing from right ahead to 70 deg. abaft the beam and two from right aft to 70 deg. before the beam; the other two are on the broadside. The guns are separated from each other by steel splinter-proof bulkheads. Ten of the 3-pounder quick-firing guns are mounted on the superstructure over the upper deck citadel. The guns, barbettes, and ammunition hoists are all to be worked by electricity, the ammunition for the heavy guns and secondary battery being provided through separate armoured tubes. The engines are intended to develope 6000 indicated horse-power under natural draught, giving a speed of 16 knots, and 8500 indicated horse-power under forced draught, the corresponding speed being 17·5 knots. The coal capacity is 500 tons, giving a cruising radius of 3000 miles at 10 knots.—*Journal of the Royal United Service Institution.*

INSTITUTION OF ELECTRICAL ENGINEERS.

THE UTILISATION OF WATER POWER, ESPECIALLY WITH A SMALL FALL, WITH SOME EXAMPLES OF PLANTS FOR THE GENERATION OF ELECTRICAL ENERGY.

(*Concluded from page* 549.)

Assuming that the water power available at Brantham Mills were applied for the generation of electric energy, it would, in the first instance, be necessary to obtain a conveniently high speed to drive an electrical generator without much intermediate gearing.

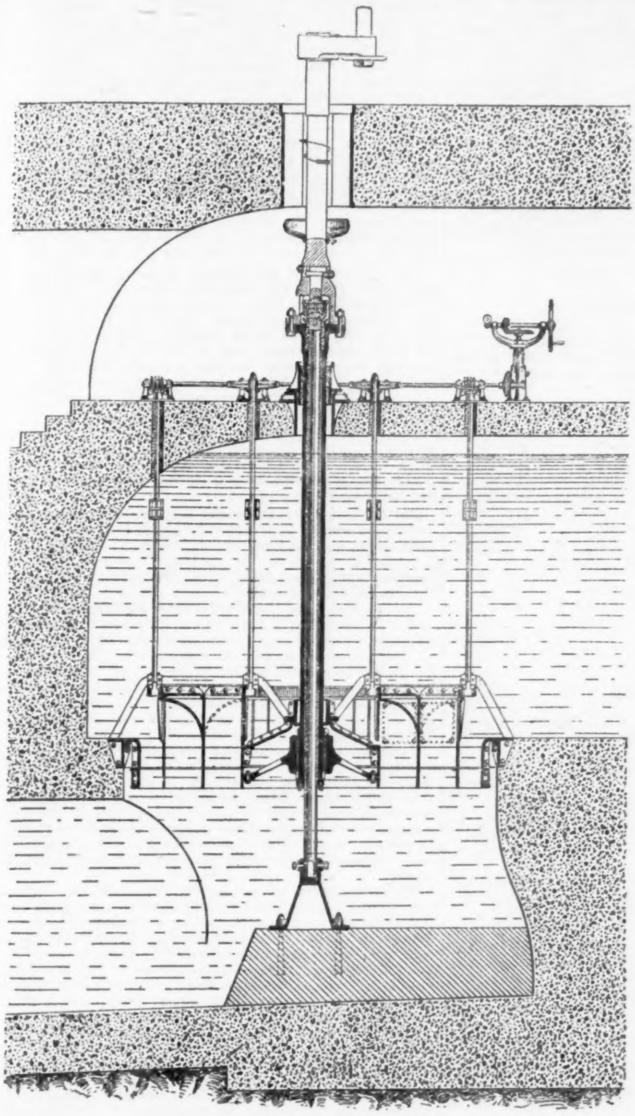


Fig. 6—Turbines of the Waterworks, Geneva

A turbine similar to the one actually working could be made for exactly these conditions, running at 30 revolutions per minute, and a pair of bevel wheels put in of such proportions as to give the first motion shaft a speed of 150 revolutions per minute. This speed would be very suitable to drive a dynamo of 40-horse power by means of a belt or ropes. A higher speed of the turbine than 30 revolutions would, for such a low fall, only be obtainable at the expense of efficiency. As in this special case the fall, and consequently the power, varies with the rise and fall of the tide, the full power of the turbine can, of course, only be relied on during fifteen or sixteen hours every day. The power produced during the time when the fall is diminished beyond the limit at which it is 40-horse power, and at less than the normal speed, could probably be applied to charge electrical accumulators. The construction of the turbine shaft deserves some notice. The space underneath the turbine being always filled with water, and, therefore, inaccessible, the plan for the footstep is placed on top of a column round which the hollow cast iron shaft revolves. The upper part of the turbine shaft is widened, and contains an adjustable steel pin which revolves in the pan or cup, filled with oil. Although a well-constructed footstep will last for years without requiring repairs, an easy access to it is of great advantage.

Similar turbines were erected by me in other mills near Norwich, Reading, and Lewes. In all cases the fall varies between—23in.—2ft. 6in. and 6ft., the reduction of the fall being caused by floods, while the water supply varies in the proportion of about 1 to 4. In each case the local conditions were carefully investigated and the turbine constructed accordingly. The good results obtained in each case are due to the careful adaptation of the turbine to the conditions. The importance of a careful consideration of local conditions is evidenced by several failures which were recently brought under my notice. In one of these instances, the turbine—which in itself is a very good motor—gives very poor results owing to the disregard of the actual conditions of the locality. Even the construction of some details of a turbine depends sometimes on these conditions, and in several cases now under consideration I have had to depart from the general practice of designs of turbines, in order to secure the highest results when most required.

How varied the construction of a Jonval turbine may be, will be shown by the following examples. The turbines of the Geneva Waterworks, built by Messrs. Escher, Wyss, and Co., of Zurich, work under a maximum fall of 12ft. during the winter season, when the water supply is shortest, while during the summer season the water supply stored up in the mountains in the shape of snow and ice is abundant. The large summer supply reduces the fall, however, to 5ft. 7in. The power of each turbine, of which there are now seventeen at work, is 210 actual horse-power, and they run at a uniform speed of thirty-six revolutions per minute, whether the fall is 5ft. 7in. or 12ft. The cost in this case was a secondary question; the turbines have, therefore, been provided with the best possible arrangements to suit the large variations of the fall and quantity of water. The drawing shows three concentric rows of buckets. The outer row alone will develope 210-horse power under the maximum fall of 12ft.—its outside diameter is 14ft. Each of the two inner rows of buckets is provided with a revolving gate, working separately. Each turbine drives a pair of double-acting plunger pumps direct, the crank common to both pumps being fixed on the vertical turbine shaft.

An interesting turbine installation, under a fall varying from 10ft. 9in. to 8ft. 10in., in connection with electrical generators, is that at Baden, in Switzerland. It was described in *Engineering*, November 1st, 1895. This plant was erected to supply the town of Baden with electric light, and the necessary driving power to the new works of Messrs. Brown, Boveri, and Co., the well-known electrical engineering firm. The fall had to be created by a weir, and a canal about 2500ft. long, which added considerably to the cost of the plant. Each of the three turbines is of the Jonval type, giving off 200 brake horse-power. It is impossible to build a turbine of that power for the fall available in this case, which would run with a speed high enough to drive a generator direct. The turbines run at 40 revolutions per minute, which speed is maintained under the varying fall by means of gates for the inner row of buckets. The generators—two-phase dynamos of the horizontal type, made by Messrs. Brown, Boveri, and Co.—run at 200 revolutions per minute, and are driven direct off the turbine shaft by means of a pair of bevel wheels. The exciter dynamos, of which there are three of 10-horse power each, are driven each by a separate turbine. These small-power turbines naturally run at a higher speed—namely, 180 revolutions per minute—and drive, therefore, the exciter dynamos without any intermediate gearing.

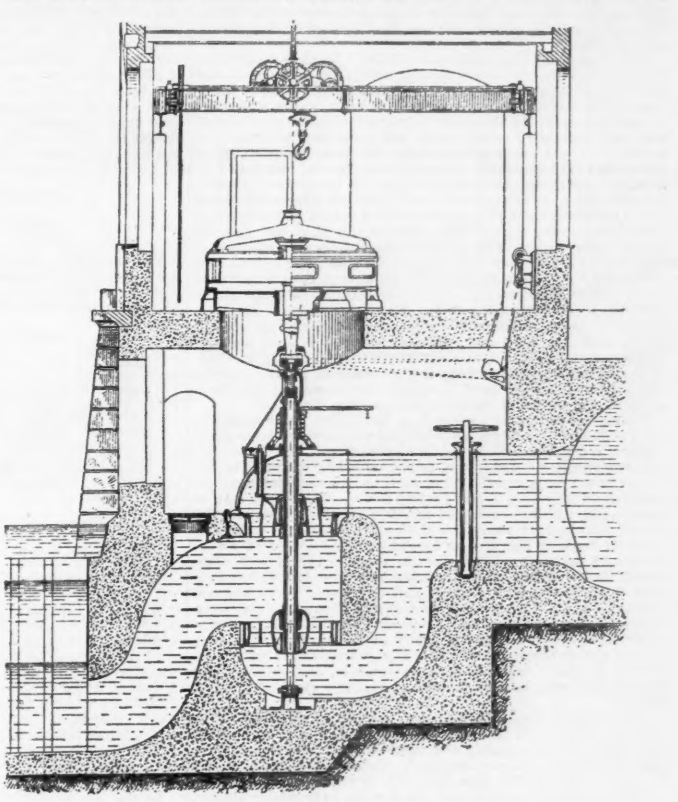

Fig. 8—Turbines at Zufikon-Bremgarten, Switzerland

In most cases in this country where a good water supply is available, the fall will be rather lower than 10ft. or 12ft.; it will, therefore, require intermediate gearing to drive a high-power generator, and it will even not often be possible to connect it direct with the first main shaft driven off the turbine by bevel wheels. Belt drives are very convenient to get up the necessary speed of dynamos, but for large power they are very expensive, and absorb a considerable amount of the power in friction. The ordinary round hemp and cotton rope is objectionable, on account of requiring frequent repairs and re-splicing. During an inspecting tour in Switzerland last summer, I came across a new kind of hemp rope, which seems to supply just what is wanted to drive large power dynamos. A piece of this patent rope is here for inspection. It is a plaited rope of extreme pliability, which does not stretch. I found this rope working at the generating station of Schaffhausen. The power at the generating station is transmitted from the countershafts, driven off two turbines of 300-horse power each by means of bevel wheels, on to the generators by means of ten such ropes, 1¾in. thick. The rope pulleys on the dynamos have a diameter of 5ft., running 300 revolutions per minute. The rope pulleys on the countershaft have a diameter of 13ft. 6in., and the distance between the centres of shafts is 51ft. The power is electrically transmitted to a spinning mill about half a mile distant from the generating station. The secondary station consists of an electro-motor of 200-horse power, coupled directly to a main line shaft, and two electro-motors of 190-horse power each, coupled together. The latter, running at 300 revolutions per minute, carry a rope pulley of 5ft. diameter with fourteen grooves; 100-horse power are transmitted by four such ropes to a shaft 21ft. above the electro-motor, at an angle of 51 deg., while the remaining 250-horse power are transmitted to another shaft on about the same level and 17ft. 8in. distant, running with 130 revolutions per minute. In spite of the unfavourable relative position of the shafts, these ropes work with extreme regularity and easiness, and their adaptation has, according to the manager of the spinning mill, put an end to the trouble and frequent stoppages caused by the breaking of the round ropes which were previously used.

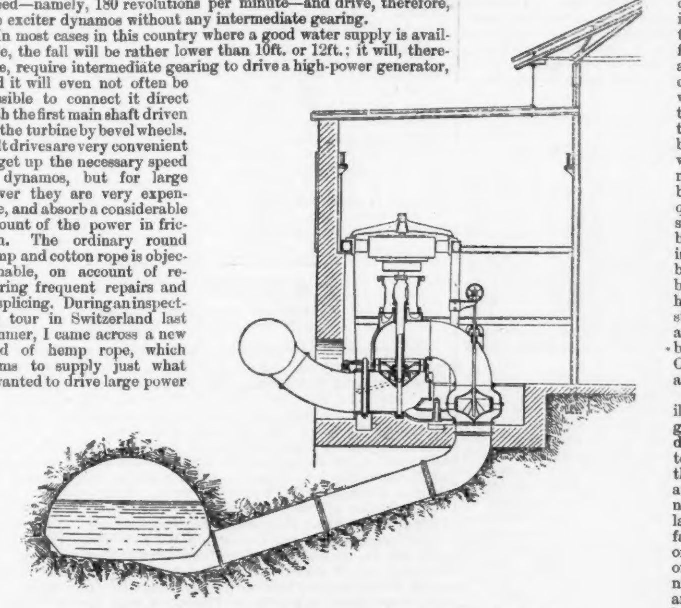

Fig. 7—Turbines at the Aluminium Works at Neuhausen, Switzerland

Returning to the description of water-power plants proper, two more examples in connection with the generation of electricity deserve to be mentioned, showing how certain objects can be attained by a special construction. One of these is the installation of five new turbines for the aluminium works at Neuhausen, on the Rhine Fall, in Switzerland. One of these turbines is here illustrated. Each of these turbines gives off 610 brake horse-power under a fall of 66ft., with a quantity of water of 6500 cubic feet per minute. With the high fall a high speed suitable for driving the dynamo direct is naturally obtained—an arrangement which has also been adopted in this case to economise space. On the other hand, the load on the footstep of a turbine of the power mentioned by the pressure of the water, in addition to the weight of the armature of a generator of corresponding dimensions, is so great that a special arrangement had to be adopted to release the footstep of at least a part of that load. In order to overcome this difficulty, the turbine has been reversed, the water passing through the turbine upwards, acting, therefore, in the opposite direction to the weight of the machinery. The boss of the turbine wheel is, moreover, formed into a piston, working in a cylinder, to which water under the pressure corresponding to the fall is admitted, thus counteracting again the weight of the moving parts of the turbine and dynamo. The water, after passing through the turbine, is conducted to the tail-race through a suction tube, the turbine being placed 15ft. 9in. above the tail water. It runs at 150 revolutions per minute, and is a single Jonval turbine. To regulate its speed, if required, a ring gate is inserted in the suction tube, while it can be stopped by a throttle valve in the wrought iron tube taking the water to the turbine. The total power now utilised by these aluminium works is 4550-horse power. The turbines were constructed by Messrs. Escher, Wyss, and Co., of Zurich, and the dynamos by the well-known electrical works at Oerlikon. Each dynamo is of 7500 ampères and 55 volts.

The last turbine installation here illustrated is that at Zufikon-Bremgarten, also in Switzerland. The drawing shows another arrangement to counteract the weight carried by the footstep, and at the same time an arrangement by means of which the necessary speed to drive a dynamo of large power direct under a medium fall is obtained. The plant consists of four sets of double Jonval turbines of 325 brake horse-power each, running at 115 revolutions per minute, and a smaller Jonval turbine of 34 brake horse-power, driving two exciter dynamos, running with 210 revolutions per minute, and was erected to supply electric light to the neighbouring town of Wohlen, and driving power to the new works of Messrs. Escher, Wyss, and Co., of Zurich, and a large flour mill close by these works. The distance over which this power is transmitted is about eleven miles. The fall is 17ft. 6in., and was obtained by building a dam across the river Reuss, and a tunnel about 1100ft. long across a hill round which the river flows at a rather high speed. The water is divided between two Jonval turbines fixed on one common shaft, so that it passes upwards through the lower wheel and downwards through the upper wheel. By distributing the water in this manner, the diameter of each turbine is reduced, and the speed consequently increased. At the same time the pressure of the water, which would otherwise act on the footstep, is entirely counterbalanced. The central part of the lower wheel is, moreover, formed into a disc, on which the water presses from below, releasing the footstep also partly by the weight of the revolving parts of the turbine and the dynamo. The space between the two turbines on each shaft is connected with the tail-race by a flume formed of concrete, which acts as a suction tube. This turbine plant was also erected by Messrs. Escher, Wyss, and Co., and the dynamos were built by the Oerlikon works. The examples given above of the utilisation of water power may be considered as representative types of successful installations under different conditions. They are sufficient in number and in variety to prove the necessity of a selection from motors which are different in principle, and of the careful adaptation of the turbine selected to the local conditions and requirements.

A turbine installation under a low fall will be more costly than one under a higher fall; it is, consequently, of special importance to obtain the highest possible efficiency, even at an extra expense, under a low fall. The cost of the turbine itself is only a fraction of the total outlay for the plant, including foundations, connection with the machinery to be driven, and sometimes a weir and a canal. The cost of these permanent structures exceeds that of the motor; it is, therefore, a penny wise and pound foolish policy, after putting in the permanent structure, to try and cut expenses by putting in a turbine of insufficient capacity or inferior efficiency. The commercial value of a water power depends rather more on the annual outlay on the same than on the first cost, and the annual outlay for the work obtained from the power is the smaller the higher the efficiency of the plant. The efficiency of a turbine which can be obtained and honestly guaranteed, even if the fall is low, is about 75 per cent. Eighty per cent. and a little over is sometimes obtained under favourable conditions, and has been proved by careful tests made by responsible experts; but an efficiency of 85 and 90 per cent., sometimes claimed, is never reached, if the quantity of water be accurately measured during the test. If the efficiency of the turbine is guaranteed at all, it should be stated not only for the most favourable conditions, but also for a reasonable minimum of the fall or the quantity of water.

In many instances within my own knowledge, water power, in itself sufficient to drive the machinery of a factory, but improperly utilised, is supplemented by artificial power, produced by steam, gas, or oil engines. The loss of money caused by the waste of the cheap power from a running stream in this manner amounts certainly to a big sum in this country alone. The annual cost of such auxiliary power, calculated for 3000 working hours, may be put at three to four times the cost of water power, and calculated for 6000 working hours, four to eight times the cost of water-power. A judicious utilisation of the water power in such cases would not only result in an enormous saving of money, but in a gain of a large amount of power now unutilised. Most factories are closed at night time, when the water is allowed to run away without being made use of. Assuming that the water power is insufficient to drive all the machinery in the daytime, while it is wasted during the night, electrical storage batteries in connection with a generator might very advantageously, and perhaps with greater economy, be used instead of auxiliary steam, gas, or oil engines.

It seems probable that in the near future the electrical transmission of power will take the place of shafting and belt drives in factories, when certainly the waste of water power would be prevented in the manner suggested. Owners of factories driven by water power might even find that by improving their water power they obtain spare power which could be profitably applied by the generation and distribution of electrical energy in the immediate neighbourhood. I may add that the majority of large-power central stations now being erected in Switzerland for the generation and distribution of electrical energy are mostly utilising small or medium falls varying between 10ft. to 30ft. The storage of water in the shape of snow and ice on our mountains provides us with a good water supply during the summer, but the low temperature in winter reduces that water supply very considerably. The water power there is just as variable as in other countries, and those falls which can be advantageously utilised on account of being situated in the inhabited and industrial districts are often not any higher, or much higher, than in this country; the only difference being that such small falls occur more frequently, rendering a concentration of large power in one place easier, and perhaps less costly. Still, it is my conviction that concentration of water power for the distribution of electrical energy, or for the generation of a large amount of electric current, as required for electro-chemical and electro-metallurgical processes, is possible in many places in this country without going into prohibitive expenditure for canals, &c.

In conclusion, I hope to have succeeded in my endeavour to show how water power under low falls can be, and is, very advantageously and economically utilised for the generation of electrical energy; and that a very large amount of water power is now running to waste which could, in conjunction with electrical machinery and apparatus, be turned to profitable account by such a hearty co-operation of the electrical and the water-power engineer as has resulted in such success of commercial enterprise in my native country.

LAUNCHES AND TRIAL TRIPS.

On Thursday, the 21st ult., the s.s. Veva, built by Messrs. Ropner and Son, of Stockton-on-Tees, to the order of Messrs. G. Pyman and Co., of West Hartlepool, made her official trial trip. The steamer proceeded down the river to the Tees Bay, where her compasses were duly adjusted, after which a very pleasant and satisfactory run was made at sea, the engines working very efficiently and steaming easily. The owners were represented by Captain Pyman, who has superintended the building and fitting out of the steamer, and who expressed himself as highly satisfied with the performance of the vessel. At the conclusion of the trial trip the steamer proceeded on her way to Hull, where she loads for the River Plate.

The saloon steamer Talisman, the most recent addition to the fleet of the North British Steam Packet Company, made a trial trip on the river on the 26th ult. The vessel, which is one of the most handsome passenger steamers on the Clyde, was built by Messrs. A. and J. Inglis, and was placed on the passage between Craigendoran and Rothesay. She has been specially designed with a view to rapid sailing and the comfort of her passengers. Her length is 215ft., and she is 23ft. in breadth, by 8ft. in depth, her tonnage being 290 tons. Her engines, which are also by Messrs. Inglis, are of the single diagonal surface condensing type, with a 52in. cylinder and a 6ft. stroke. She has been built to meet the Board of Trade requirements, and is certified to carry 1254 persons. Leaving Craigendoran, in delightful weather, shortly after noon, the ship, which was under the command of Captain M'Kinlay, crossed to the Cloch Lighthouse for the purpose of making a speed trial to the Cumbrae Light. The speed attained was 18·5 knots, equal to 21·3 statute miles an hour, a result which was regarded as highly satisfactory. The Talisman is the fastest steamer of her size ever built at the price.

On the 27th ult. a further addition was made to the fleet owned by Messrs. Houlder Brothers and Co., of London, by the launch of a large screw steamer by Messrs. Workman, Clark, and Co. The vessel was named the Denton Grange by Mrs. Alfred Houlder, of Holmewood, Purley, Surrey, in the presence of a large assemblage. A party, at the invitation of the builders, then proceeded on board the Langton Grange, which proceeded down Belfast Lough on her trial trip. This vessel has been specially designed to suit the requirements of Messrs. Houlder's trade to Australia, South America, and the Cape. The leading dimensions are: Length, 420ft.; breadth, 54ft.; depth, 32ft. 5in.; with a gross tonnage of 5850, and built to Lloyd's highest class, with Board of Trade requirements complied with for carrying passengers. The vessel is divided into eight compartments, and several of the holds are insulated, and the refrigerating machinery fitted up by Messrs. Hall, of Dartford, on the carbonic gas system. Eleven powerful steam winches of a special design, having extended shafts with large barrels and frictional brakes, are provided for working cargo, the derricks being suspended from steel derrick posts. Exceptional good stowage has been secured by dispensing with hold beams and substituting continuous side stringers with a minimum projection. The upper deck is covered with erections for over three-quarters of the length, having on the bridge deck a large deck-house for the passengers and officers. A complete installation of electric lighting has been fitted throughout, including arc lamps. Arrangements have been made for conveying cattle, and upwards of 700 can be carried on the upper decks. During the day the vessel was run on the measured mile, and an average speed of 13½ knots was, we are informed, attained. The machinery has also been constructed at the builders' works, and is capable of developing about 3200 indicated horse-power, with steam supplied from three boilers with Howden's forced draught, the superintendence of this department being carried out by Messrs. Esplen, Son, and Swainston, and the supervision of the ship under Mr. Copeland K. Etheridge, Messrs. Houlder's marine superintendent.

AUSTRALIAN NOTES.

The quarterly report of the Railway Commissioners for New South Wales for the quarter ending 31st March last, together with the particulars for the corresponding period of the previous year, is summarised as under:—

Railways.	Quarter ending 31st Mar., '95.	Quarter ending 31st Mar., '96.
Miles open	2531	2531
Revenue	£647,875	£648,982
Expenditure	£368,959	£372,832
Train miles run	1,867,262	1,890,021
Earnings, per train mile	6s. 11¼d.	6s. 10¼d.
Expenditure, per train mile	3s. 11¼d.	3s. 11¼d.
Percentage, expenditure to earnings	56·95	57·45
Number of passengers	4,846,193	5,236,431
Tonnage of goods traffic	917,152	1,015,538
Tonnage of live stock traffic	40,285	40,790
Tramways.		
Miles open	61	61
Revenue	£73,366	£75,143
Expenditure	£54,221	£53,781
Train miles run	638,930	681,619
Earnings, per train mile	2s. 3¼d.	2s. 2½d
Expenditure, per train mile	1s. 8¼d.	1s. 7d.
Number of fares collected	17,343,232	17,735,940
Percentage, expenditure to earnings	73·90	71·57

The total revenue derived from goods traffic decreased by £11,642, general merchandise, minerals, hay, straw and chaff, and wool showing an aggregate decrease of £20,659, while live stock, coal, and miscellaneous show an increase of £9017. In the coaching traffic the increase of £12,749 was made up by £5188 in first-class, £5360 in second-class, and £2201 in parcels.

The expenditure for the quarter shows an increase of £3873, which is accounted for by the following special debits:—Workshop staff working full time. One day's extra wages included in consequence of leap year. Heavy exceptional expenditure for repairing damage caused by floods on the Bourke and Cobar lines in February last.

In the proposed Overhead Wire Electric Tramway now before the Public Works Committee, to be laid from Circular Quay, Sydney, to the Railway Station and Pyrmont, a length of 3 miles 12 chains of double line, the following shows the particulars of cost.—Cost of permanent way, including alterations of pipes and car shed, £72,000; overhead wires, bonding, telephones, &c., and power cables, £15,000; generating power at engine house, rolling stock, and motors, £36,000; total estimated cost of construction, £123,000. Annual cost:—Interest at 3¼ per cent. on capital cost, £3997; estimated cost of motive power and car repairs, including car drivers, £15,000; estimated cost of permanent way maintenance and repairs, £2500; estimated cost of conducting traffic and general expenses, £11,000; total estimated annual cost, £32,497. Annual revenue:—Estimated value of passenger traffic, £45,000; estimated annual profit, £12,503; or equal to over 10 per cent. on investment.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

Good attendance on 'Change. The holidays affected the shipments of steam coal during the past week; the demand is now good with prices steady. House coal shipments are moderate, with prices weaker. Tin-plates in fair demand, with prices steady. The iron and steel works are all fully employed. Pitwood firmer in price.

Coal: Best steam, 8s. 3d. to 8s. 6d.; seconds, 7s. 9d. to 8s.; house coal, best, 9s. 9d. to 10s.; dock screenings, 5s.; colliery small, 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 46s. 10d.; hematite warrants, 47s. 5½d. f.o.b. Cumberland; Middlesbrough No. 3, 37s. 6d. prompt; Middlesbrough hematite, 44s. 10d. Iron ore: Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel: Rails, heavy sections, £4 12s. 6d.; light ditto, £5 f.o.b.; Bessemer steel tin-plate bars, £4; Siemens tin-plate bars, best, £4 2s. 6d.; all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel, coke, 9s. 3d.; Siemens, coke finish, 9s. 6d. ternes, per double box, 28 by 20 C, 19s. to 20s. 6d. Pitwood: 16s. 6d. Freights firmer.

AMERICAN NOTES.

(From our own Correspondent.)

New York, May 27th.

Interim capital because of dulness is seeking temporary employment in this city on long time at 4½ per cent. Net earning on 168 railroads for first three months of the year are over 1 per cent. less than same time last year. Business is much depressed all over the Sates because of uncertainty, generated without cause, in the public mind that a political platform of an equivocal character will be formulated at St. Louis on June 18th. There will not be any appreciable expansion of the volume of business until after July 1st. The iron trade holds its own; furnace production averages 190,000 tons per week. Average weekly excess of production above requirements for several months 12,000 tons. Output is now less. Prospective requirements are increasing, and the consumption of pig during the last half of the current year will not be much, if any less, than 200,000 tons per week, and certainly not if construction is begun upon some 2800 miles of road, which railway authorities say must be done soon. The American people are bent on Protection, and the political party that does not "throw up both hands" at the command of eight million votes next November will be given a permanent vacation.

Trade and Business Announcements.—The senior partner, Mr. Stephen Pewtress, in the firm of E. Marlborough and Co., 51, Old Bailey, London, E.C., retires, and his son, Mr. S. Leslie Pewtress, who has long been associated in the management of the business, becomes a partner.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(From our own Correspondent.)

There was an average attendance on 'Change at Birmingham to-day—Thursday—and a healthy business tone prevailed. The trades showed a steadier tone, and orders were given out in many cases when they were postponed on account of the late holidays. Moreover, there was more disposition to do business, and operations in the works have been well resumed, with a good record of orders awaiting execution. The home trade is in a moderately healthy condition, and the foreign demands show a well sustained amount of business to be forthcoming. The general condition is encouraging, thought at present there is no inclination on the part of buyers to give more money. Manufacturers now hold sufficient orders to carry them on through the quarter, and steady inquiries are made for prompt supplies of material. The best marked bar iron houses report a moderate volume of business at £7, with the usual 12s. 6d. extra for the Earl of Dudley's L. W. R. O. brand, and the demand for merchant iron at £6 to £6 5s. keeps up. The common bar iron manufacturers are fairly well booked at £5 5s. to £5 10s. There is a more active trade moving in black sheets at £6 10s. to £6 15s. for doubles, and £7 15s. for lattens, and a fair business is doing in hoops and thin strip at £6 7s. 6d. The tube strip makers report fresh offers for renewing the expiring orders. Angles are £5 15s., stamping sheets £9 10s., and nail rod £6 10s. Galvanised sheets in Liverpool are £10 2s. 6d. to £10 5s. for 24 gauge.

The accountants to the Midland Iron and Steel Wages Board presented to the Sliding Scale Committee, this week at Dudley, their bi-monthly certificate of the average ruling price of manufactured iron for March and April. This was £5 15s. 4d. per ton, compared with £5 16s. 8d. in January and February, £5 15s. 3d. for November and December. It will be perceived that during the first two months of the year the value advanced by about 1s. 5d., nearly all of which is not taken off again. This reduction of 1s. 4d. is insufficient to alter wages, which remain at 7s. 3d. for puddlers, and millmen in proportion.

The steel makers are busy, and further orders are coming to hand at £4 5s. for Bessemer blooms and billets of Staffordshire make, £4 2s. 6d. for similar steel imported from the North, and £4 12s. 6d. for Siemens billets. Girders and angles are £5 10s., and boiler plates £6 5s.

For pig iron a steady record of contracts is announced, and makers are sending their output into consumption, while prices are sustained at cold-blast pig, £4 10s.; South Staffordshire all-mine, 55s.; part-mine, 40s. to 42s. 6d.; and cinder pig, 35s. Northampton forge is 39s. to 40s.; North Staffordshire and Derbyshire, 41s.; and Lincolnshire, 44s.

At a meeting of the Council of the Walsall Chamber of Commerce on the 1st inst., Mr. T. A. Smith announced that the result of the interview with the borough member was that he would take charge of the Council's suggested amendments to the Locomotives on Roads Bill in the House of Commons. The President read a further batch of communications from chambers of commerce, agricultural associations, and private gentlemen approving of the proposed amendments, but in some instances suggesting that the desired end could be better attained by regulations than by an embodiment of the proposed alterations in the Bill. Lord Dartmouth wrote that he considered the amendments fair and reasonable. Sir David Salomons considered them unnecessary, as did the "Self-propelled Traffic Association." The President suggested that, in deference to the views expressed in some of the communications, they might reconsider the question of speed; and on the proposition of Mr. Hill, seconded by Mr. Scott, it was agreed to name six miles as the speed in towns, and twelve miles in the country.

The recent offer by a Canadian Syndicate to purchase the system of the Birmingham Central Tramways Company is still in abeyance, and the Public Works Committee are preparing a report to be presented to the City Council on the matter. The offer made is equivalent to the par value of the shares, plus a bonus of £1 upon the ordinary stock. Some members of the Council favour an alternative suggestion to the effect that the Corporation of Birmingham should follow the example of Glasgow, Leeds, and Huddersfield, and embark itself upon working the tramway traffic.

The West Bromwich and District Miners' Association has been in existence for about thirty years, and during that period there has been paid £33,661 for death claims, £5800 to outside trades, and £22,348 for strikes—making a total of £61,809. At a meeting of that body a resolution has been passed pledging members to continue loyal to the South Staffordshire and East Worcestershire Coal Trade Wages Board, and declaring that its sliding scale system of regulating wages is the best ever instituted in the mining district of the Black Country.

The engines of the South Staffordshire Mines Drainage Commissioners have had to deal during the month with a rainfall of ·37 of an inch only. In the Old Hill district twenty-two of the fifty canal basins agreed to be tested in March last have been dealt with and found more or less defective; and a further number of forty basins are arranged for testing at early dates.

Dairy engineers are expressing satisfaction that this week the Warwickshire Chamber of Agriculture has adopted the following recommendations of a special committee:—"That the principle of combination and co-operation for the sale and distribution of farm produce is a good one. That it is desirable that companies be established at convenient centres, both for the formation of dairy factories and for opening shops for the sale of agricultural produce. That in forming companies it is desirable that preference be given in the allotment of shares to consumers as well as producers, and that all sales be conducted on a cash basis. That the practical details and results of Lord Winchilsea's scheme be carefully watched and considered, and that Lord Winchilsea's invitation to inspect the locality of its operations be accepted." The Chamber also resolved: "That the present commitee be asked to continue its investigations, with power to add to their number."

NOTES FROM LANCASHIRE.

(From our own Correspondents.)

Manchester.—Business in the iron trade here has been resumed after the holidays in a much more satisfactory manner than is usual following the protracted Whitsuntide stoppages. Prices for raw material have shown a hardening tendency, and there has been a considerable weight of buying which fully bears out the anticipations in my previous notes as to the temporary character of the weak depressed tone recently prevailing, and the general feeling of confidence with regard to the future. Operations have, of course, scarcely got into full swing again, the holidays in some of the engineering centres extending until Tuesday, whilst pits in the Manchester district did not make a full start until Wednesday. Although collieries are so short of orders that a protracted stoppage is perhaps rather welcome than otherwise, engineering establishments are in the position that except for the customary repairs, the whitewashing of shops, &c., that are put in hand at Whitsuntide, they could very well have dispensed with any stoppage at all, as in most cases they are pressed to get out in anything like reasonable time the orders they have already on the books, and with regard to new work, of which there is plenty, it is, as a rule, more a question of delivery than of securing orders.

For the opening market after the Whitsuntide holidays, the 'Change meeting at Manchester, on Tuesday, was well attended, and a strong, active tone characterised the market generally. Considerable sales were reported in Lincolnshire pig iron, and in one or two cases makers have put up their list rates 6d. per ton for forge numbers, bringing them back to 41s. net cash, delivered here, and this advance, it is expected, will, at the close of the week, be followed by other concerns, a meeting of the Lincolnshire makers being held to-day, Friday. This will tend materially to strengthen the position of local makers, who owing to the weakening tendency in Lincolnshire, have been doing little or nothing in forge qualities, and have had to regulate their quotations by the low prices ruling for forge numbers coming from the above district. Both local and district foundry qualities remain without quotable change, averaging 46s. 6d., less, 2½ for No. 3 foundry, Lancashire; 43s. net cash for foundry Lincolnshire, and 45s. 6d. to 46s. 6d. for Derbyshire foundry, delivered Manchester, although Derbyshire is, if anything, a trifle easier. As regards outside brands, prices have stiffened up somewhat; good foundry Middlesbrough is not quoted under 45s. 10d. to 46s. 4d. net cash, delivered by rail Manchester, and 44s. delivered Manchester Docks. Scotch iron is still rather irregular so far as immediate delivery is concerned. Eglinton has been offered as low as 46s., delivered ports; and 48s. 3d., dock quays, Manchester; but this is nearly 1s. under makers' quotations and about 6d. under the average market prices. Glengarnock is also irregular, ranging from 46s. 9d. upwards, delivered Lancashire ports. In some special brands of Scotch iron, however, business has been done at much better prices relatively.

A rather unsettled tone prevails in the finished iron trade owing to the continued low cutting of one of the large manufacturing firms, to which I have previously referred, and whose bars, it is reported, are being offered at more than half-a-crown per ton under the general quoted rates. This is naturally being very strongly resented by the other Lancashire makers, who have still sufficient orders on their books to keep them fully going for some time to come, and although just at present they are not booking much new business, they are not attempting to compete with the reduced prices which the firm above referred to are prepared to accept, as they believe that by waiting there will be a strong, steady improvement in the market with the turn of the half-year. For delivery in the Manchester district they consequently remain firm in quoting £5 10s. as the minimum, whilst North Staffordshire bars average £5 10s. to £5 15s., delivered here. Sheets are stronger, and now range from £7 to £7 5s.; hoops remain at £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths, delivered Manchester district, with 2s. 6d. less for shipment.

In the steel trade a steady tone is maintained, and there is no quotable change in prices. For good foundry hematites makers are firm at 58s. to 58s. 6d. less 2½; steel billets are obtainable at £4 7s. 6d. net cash; bars at a trifle under £6, whilst for boiler plates, £6 5s. to £6 7s. 6d. remain about the average figures for delivery in this district.

All descriptions of manufactured metal goods are in brisk demand, and local makers have quite a pressure of orders. The railway companies have been placing a large quantity of work; requirements of general engineers are also heavy, and there has been a considerable demand for the various fittings required in connection with the Government work recently given out. This pressure of work has caused another advance in prices of ¼d. per pound, and delivered Manchester district quotations are now as below:—Solid drawn brass tubes, 6¾d.; brazed copper tubes, 7¾d.; solid drawn copper tubes, 8d.; brass condenser tubes, 8¾d.; brass wire, 6d.; copper wire, 7d. to 7¼d.; and rolled brass 6d. per pound. Yellow metal plates, which were not at first included in the general advance, have since also been put up ¼d. per pound.

Messrs. Nasmyth, Wilson, Limited, of the Bridgwater Foundry, Patricroft, have in hand several special orders for exceptionally powerful presses. One of these, which is being sent out to India, and is constructed for dealing with special material, is to work at a pressure of five tons per square inch. Another order they have in hand is for a very large hydraulic press for Egyptian cotton, the total weight of which, when complete, will be about 180 tons. This press is so arranged that steam is utilised for part of the action, and by means of this combination the press can turn out sixty bales of cotton per hour. The firm are also exceptionally busy with orders for their special steam stamps, which have been largely in demand for bicycle forgings, and in their locomotive department they are also well engaged, the orders including a number of locomotives for the Japanese railways.

Some time back I referred to Mr. Benjamin Goodfellow, of Hyde, having secured the contract from the Manchester Corporation for the engines required for the extension of the electric lighting installation. This contract, which includes eight engines, each of 400-horse power, is now approaching completion, several of the engines having already been put down, and given, I understand, every satisfaction. Six of these engines are of the inverted vertical type, and the two others horizontal, and the whole of them are fitted with Corliss valves, which, I am informed, have been found an improvement upon the slide valves supplied with the engines put down in the section of the electric works first completed.

The only change to notice in the coal trade is, perhaps, a steady weakening in prices. Notwithstanding the protracted stoppages of the pits, all descriptions of round coal hang upon the market. Better qualities, suitable for house-fire purposes, met with only the slowest possible demand, and, apart from small retail orders, list rates are to a large extent little more than nominal. In the lower descriptions of round coal for steam and forge requirements there is continued excessively keen competition, with all sorts of prices taken for contracts or to secure orders for anything like quantities, 5s. 6d. to 6s. being the full average figures at the pit mouth for ordinary qualities. Tenders are now being sent in for the gas coal contracts, and to secure these prices are being cut a shade lower than even last year, especially in the commoner qualities. It is too early as yet to give any definite idea as to the actual prices, as none of the important contracts are yet settled, but from what I can gather they are not likely to be more than about 6s. to 6s. 3d. for ordinary Wigan four-feet, and about 7s. for best screened Wigan Arley gas coals. At the pit mouth, engine fuel, if anything, is rather more plentiful in some quarters, especially where pits have not been closed over so long a period for the Whitsuntide holidays, whilst the mill stoppages in the manufacturing centres have necessarily for the time being restricted requirements for engine purposes. Prices, however, are firm at fully late rates, averaging 3s. to 3s. 6d. for common slack to 4s. 6d. and 5s. for better qualities, at the pit mouth.

No improvement can be reported as regards the shipping trade, and 7s. per ton, delivered Garston Docks or High Level, Liverpool, remains about the average figure for ordinary steam coal.

Barrow.—There is a distinct improvement to note in the hematite pig iron trade this week, and since the holidays business has not only improved but prices as well, and users are in the market for big forward deliveries. The furnaces in blast number 39, and an increase is expected, as makers are more fully sold forward than they have been for some time past. The production is all for immediate consumption, and the stocks are held very firmly. Bessemer qualities of iron are in liberal demand on home as well as on general account, but some assurance of the continuance of activity can be obtained from the fact that local makers of steel are likely from present appearances to remain very good customers for Bessemer qualities of pig iron. Prices are better at 47s. 6½d. net cash sellers, and 47s. 6d. buyers of warrant iron, while makers quote 49s. to 50s. nominally for parcels of mixed Bessemer Nos. net f.o.b.

There is a corresponding improvement in the iron ore trade, and the demand for native qualities has appreciably increased. Prices remain steady, however, at late rates, 10s. for ordinary sorts net at mines. Imports of Spanish ores are still very largely maintained.

Steelmakers are busy on all classes of goods, but more especially on rails and on ship and boiler plates, orders for which are numerous. There is also a good trade doing in all other sorts of steel usually produced in this district, except tin bars, which remain quiet.

Shipbuilders and marine engineers have a fair number of orders on and, but new work is expected and required if the works are to be kept regularly employed. Some good commercial orders are in the market, and some important Admiralty contracts have yet to be given out.

The coal and coke trades are heavier, but while the price of coal remains easy that of coke is firmer, and higher prices are expected.

Stocks of warrant iron have increased 1195 tons during the week. There is now in stock, 309,842 tons, an increase since the beginning of the year of 20,667 tons.

Shipping is fairly employed, 7957 tons pig iron and 7823 tons of steel were shipped from West Coast ports during the week, as compared with 3931 tons of pig iron and 8058 tons of steel in the corresponding week of last year, an increase of 4026 tons of pig iron, and a decrease of 235 tons of steel. The shipments this year so far have been—Pig iron, 131,162 tons; steel, 197,574 tons; as compared with pig iron, 109,553 tons; and steel, 152,627 tons in the corresponding period of last year, an increase of 21,609 tons of pig iron, and 44,947 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

WORK has been resumed in the South Yorkshire and adjoining coalfields after the Whitsuntide holidays, although the fine weather caused "play" to be somewhat unduly prolonged. Those engaged upon the steam coal quality were the first to get back to the pits, the others delaying their return until last Monday and Tuesday. Notwithstanding the comparatively slight quantity of coal produced, scarcely any inconvenience has been caused, as the stocks in hand were quite equal to the demand. London agents report very little business. Quotations have remained very much the same, but buyers have had a little advantage during the latter part of the week. Silkstone coal is at 8s. to 8s. 3d., and secondary sorts 7s. 3d. to 7s. 6d. Barnsley house coal in plentiful supply at 7s. to 7s. 3d. per ton.

The keen competition at present existing is having effect more severely on the thin seam coal. Best qualities can only realise 6s. to 6s. 3d. per ton, and even these prices are hard to obtain, many customers preferring to pay a little more for thick seam. There is an active request at present for steam coal. The placing of the Midland Railway's contract at 7s. for South Yorkshire, and 6s. 3d. for Parkgate for a year, indicates that there will be no disturbance in August. The Manchester, Sheffield, and Lincolnshire Railway Company have also been giving out contracts on much the same lines. A large amount of the best steam coal is being forwarded to Hull, mainly from the South Yorkshire districts. Gas coal is in good request for stacking purposes.

At several of the principal works the large stocks on hand show very clearly that the directors view the future with apprehension. The demand for small coal and slack is animated. Coke is also making satisfactory advance. Prices rule as follows:—Best slack, 3s. 6d. to 3s. 9d.; and ordinary pit slack, 2s. 6d. to 3s. Smudge makes 1s. 6d. to 1s. 9d. per ton. Coke is produced in very large quantities, and the smelting furnaces have been fully employed during the holidays. Satisfactory reports are coming in from the new ovens at the Barrow collieries, and a similar remark applies to Silkstone common. Prices range from 8s. to 12s. per ton.

The heavy industries continue in a very satisfactory condition. Armour-plate firms are full of work on Government account. Boiler makers and engineers report a steady trade. Crucible steel, best brands, are easily sold, while the output of both Bessemer and Siemens-Martin has rather increased of late. Values are firm as follow:—Hematites, 55s. to 57s. 6d. per ton, delivered in Sheffield; Bessemer billets, £5 12s. 6d. to £6; bar iron, £5 10s. at makers' works and £6 in warehouse; Lincolnshire pig iron, 39s.; Siemen-Martin steel, £7 10s. per ton, average quality. Reports from the rolling mills are most encouraging.

The values of the various descriptions of wire remain about the same. Common realises £4 15s.; guaranteed carbon, £7 6s.; and Siemens-Martin, special, £9. Old rails are rather scarcer at present, and the price has therefore advanced. Belgium has competed very keenly with English mills this year. Rather less business in cycle sections is being done in the rolling mills, although the manufacturers of material for bicycle work are exceptionally well employed.

The prosperity in the shipyards is having a beneficial effect on the demand for marine castings, heavy crank-shafts, &c. Messrs. Charles Cammell and Co. have just received an order from the Palmer Shipbuilding Company for two crank shafts for the two cruisers ordered by the Admiralty, and now building at Jarrow.

In the building trades some difficulty is reported in getting English girders. One large building for carriage and omnibus proprietors has been delayed on that account. It is understood that Northern girder firms are very busy at present, both on foreign orders and home requirements.

The lighter industries are waking up a little. The dispute in the file trade has been satisfactorily settled, and the men have resumed work at the higher wages. The demand for cutlery has again advanced, more being done in the best classes of pen, pocket, and table cutlery, but there is no diminution in the keenness of competition from Germany. The use of xylonite as a substitute for ivory—and it is wonderfully akin to it in the touch as well as the sight—is rapidly increasing. The silver and electro-plating firms in a large way of business are well employed, but the smaller establishments do not report quite so favourably. The silver, electro-plate, and Britannia metal trades are being added to the long roll of existing trade unions. The chasers, engravers, and etchers were formally organised on Tuesday evening. A determination was expressed to bring every man who is engaged in these branches into the society.

Local manufacturers are watching the motor car movement very closely. With the removal of the present restrictions on street locomotion, a rush of trade is expected, and Sheffield means to be in it, and not let the motor cars pass them as they foolishly allowed the bicycle business to do.

The drought, which ended with the beginning of gentle showers on Wednesday night, has considerably reduced the stocks of water in the Sheffield reservoirs, but not to an extent to cause misgivings. It is understood that in spite of May being so dry a month, the reservoirs contained up to Wednesday sufficient water to give five months' supply to the city. The falling of the rain will not merely swell the stores, but cut off the great quantity required for garden watering and kindred purposes, in which gross waste takes place.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

AN upward movement has been in progress in local trade this week, business has been fully resumed after the holidays, and consumers are evidently going earnestly into business, as they are recovering confidence, and having done little buying since Easter, the time is approaching when they must make arrangements for securing further supplies, and they do not think that by waiting they will be able to purchase on easier terms than those now ruling. Almost everything favours the improvement, prospects are encouraging, the stock markets are becoming stronger and more animated, railway traffic receipts increase, and political matters no longer exert a detrimental influence on trade generally. Consumers are rather anxious to buy iron for forward delivery, but sellers are not prepared to commit themselves in the face of a rising market. Exports are well kept up; indeed, Monday's pig iron shipment from the Cleveland district was the largest on record, reaching 10,750 tons, whereas in June a slackening of oversea deliveries is usual.

Prices of Cleveland pig iron this week have been advanced 3d. per ton, and a good deal of business is said to have been done at the higher figures. No. 3 Cleveland pig iron could on Monday have been bought at 37s. 3d. per ton for prompt delivery, but 37s. 6d. has been the general price since, and nothing less than that will be accepted, either by makers or merchants, and the cheap iron that was offering last week has been withdrawn. Cleveland warrants are improving in value, they were at 37s. 3d. cash when the week opened, but rose to 37s. 7d. on Tuesday, and on Wednesday closed at that. Last month Connal's stock of Cleveland pig iron was increased 4694 tons, the quantity held by them at May 31st being 198,450 tons. Of hematite pig iron Messrs. Connal held 159,524 tons, the increase for the month being 5290 tons. No. 1 Cleveland pig iron is at 38s. 9d.; No. 4 foundry is advanced to 37s.; No. 4 forge to 36s. 6d.; and white is at 36s.

The upward movement is least conspicuous in the hematite pig iron trade, for the opinion is that the output is in excess of the requirements, and the increase in Connal's stores favours that idea. Of course no reliable figures can be given as to the stocks of hematite pig in makers' hands as no returns are officially collected. It is thought, however, that the market would be strengthened if two or three furnaces making hematite were blown out, instead of more being put in. Russia, which for the last few years has been a large buyer of Cleveland hematite pig iron—taking last year between 60,000 and 70,000 tons—this year is importing very little, as more is being made at home, additional furnaces having been erected in South-East Russia. As the Russians levy such a heavy duty on imported pig iron, Cleveland makers find it difficult now to compete with native producers. The quotation for M. Nos. of Cleveland hematite pig is 46s. per ton for early delivery, but 45s. 9d. is generally accepted.

The May statistics of the Cleveland Ironmasters' Association are regarded as rather unsatisfactory, because in spite of good shipments, and practically a decrease in the production of Cleveland pig iron, the stocks show an increase of 3308 tons, while the estimate was that the consumption would be at least equal to the production. The total quantity of Cleveland pig iron held at the close of the month was 353,305 tons. The increase was not in makers' hands, however, for their unsold stocks were reduced 505 tons, and the stock in their stores 2146 tons. The accumulation was in the public stores, the North-Eastern reporting 1265 tons, and Connal's 4694 tons. The increase of 10,624 tons can be accounted for by the extra day in May over April, but actually the rate of production in Cleveland iron was lessened, seeing that the rate of increase should have been 4300 tons, if the output had been kept up at the April rate, whereas it is only 2218 tons. The production of hematite, &c., pig is again in excess of that of Cleveland iron. Of the 96 furnaces in operation, 49 were producing Cleveland iron at the close of the month, and 47 hematite, &c., there being a decrease of 2 making Cleveland iron and an increase of 3 producing hematite, &c. The Carlton Iron Company blew in a furnace during the month. What caused the estimates to be wide of the mark was that more hematite pig iron was exported than had been counted upon. The following summary of the statistics of make and stocks is interesting:—

Make of Pig Iron.

	1896.		Increase
	May	April	
	Tons	Tons	Tons
Cleveland pig iron, Middlesbrough..	115,725	114,012	1,713
Do., outside Middlesbrough	20,249	19,744	505
Do., whole district	135,974	133,756	2,218
Other kinds of pig (including hematite, spiegel, and basic pig iron), whole district	140,746	132,340	8,406
Total of all kinds, whole district	276,720	266,096	10,624

Stocks of Cleveland Pig Iron.

	1896.		Increase	Decrease
	May 31	April 30		
	Tons	Tons	Tons	Tons
Makers' stocks Middlesbrough ..	86,401	87,320	—	919
Do., outside Middlesbrough	11,235	10,821	414	—
Do., whole district	97,636	98,141	—	505
Makers' stores, whole district ..	29,684	31,830	—	2,146
Public stores:—				
N.E. Railway Company's	27,535	26,270	1265	—
Connal's	198,450	193,756	4694	—
Total	353,305	349,997	3308	—

Altogether 96 furnaces were at work, against 89 a year ago.

The pig iron shipments from the Cleveland district during May, though not the largest on record were excellent, more especially when they came after such heavy exports as those in March and April. For three consecutive months the export of pig iron from Cleveland has exceeded 100,000 tons per month, a circumstance quite unprecedented in the history of the trade. Previous to last year it was a rare occurrence to see 100,000 tons reached; indeed, it was reached only four or five times since the trade was established. Last month's shipment of pig iron was 104,191 tons—1279 tons less than in April, but 2086 tons more than in May, 1895, and 12,157 tons more than in May, 1894. The exports for the five months elapsed of this year have amounted to 451,575 tons, exceeding by 42,000 tons the previous best returns—that of 1889, when 409,592 tons were shipped. This year's figures have been 63,442 tons better than those of last year, and the deliveries, both foreign and coastwise, were the best on record. To Italy the quantity sent has never been exceeded, and it is some years since Germany, Holland, Belgium, and Canada had more than is reported for this year. The tonnage sent to Scotland has only once before been exceeded.

The finished iron and steel trades are exhibiting better features, except the steel sleeper department. The demand for steel sleepers appears to be falling off very materially, just when extensive plant at several works has been put down to manufacture the material. Engineers seem to be abandoning the use of such sleepers, especially in India, on account of their extra liability to corrosion, and the companies are returning to the use of the old cast iron pot. The ironfounders benefit by this; they had in many cases come to look upon this trade as a decaying one, but it has become active lately, while at the same time the steel sleeper trade has fallen off. Heavy steel rails are at £4 10s. net per ton at works, but it is difficult to secure this price, and transactions in other districts at a considerably lower price have been reported. Common iron bars are quoted at £4 17s. 6d.; best bars at £5 7s. 6d.; steel ship plates at £5; steel ship angles at £4 17s. 6d.; iron ship plates at £4 17s. 6d.; and iron ship angles at £4 15s., all less 2½ per cent. f.o.t.

Sir Christopher Furness, and the gentlemen interested with him in the purchase of the property of the Teesside Iron and Engine Works Company, Middlesbrough, intend very shortly to issue the prospectuses of the new companies which are being formed to carry on the works. The liquidator of the old company, Mr. Wm. B. Peat, has informed the preference shareholders that he will send them copies, so that they may individually elect whether they will in respect of their present holding take 10s. per share in preference shares in the new companies, or accept 7s. 6d. in cash.

The shareholders of the Darlington Steel and Iron Company, at their annual meeting, were averse to finding £55,000 to bring the works up to date and re-start them. They appear to have no hope of their being carried on successfully as a rail manufactory, and decided that it is advisable to wind up the company under voluntary liquidation. A meeting of shareholders is to be called to pass a resolution to this effect.

The Tees Conservancy Commissioners have had a communication from the Admiralty asking for particulars as to the dimensions, depth, &c., of the Commissioners' Graving Dock. The Commissioners have decided to memorialise the Admiralty, asking whether they would be prepared to subsidise by a money grant the Commission, in the event of that body determining to construct a large dry dock on the Tees, for the purpose of meeting all modern shipping requirements, including vessels of war. There is no graving dock on the North-East Coast large enough to accommodate a man-of-war.

The Tees Conservancy Commission are moving in regard to the tipping of blast furnace slag in Tees Bay, viz., to systematise the tipping so that it may come in useful as a foundation in case a harbour of refuge should be constructed there. Thousands of tons are tipped weekly into the bay, and other ironmasters, who are short of land, are proposing to send their slag to sea. The chairman of the Commission has had an interview with Mr. Goschen on the subject, and told him that if the Commissioners received from the Admiralty any encouragement to believe that when the proper quantity of slag had been tipped below the water the concrete works would be undertaken by the State, they would have the slag tipped in the direction indicated in Sir A. Rendel's plans, and furnish the necessary lightships. Mr. Goschen is to look into the matter.

The coal trade is brisker so far as regards the steam coal branch, and the price of best steam coal is fully 8s. 3d. per ton f.o.b. The Earl of Durham's fourteen collieries are to pass into the hands of Sir James Joicey and Co. on July 1st, and the officials have received notice to that effect.

The steel lighters which have been built by Sir Raylton Dixon and Co., Middlesbrough, for the Rotterdam Coal Shipping Syndicate, have made their first trips this week, each carrying 1000 tons of coal from the Wear to Rotterdam, and being towed by Dutch tugs. They will perform weekly voyages.

Mr. Charles Fenwick, M.P., has been nominated for the presidency of the Northumberland Miners' Association, vacant by the death of Mr. John Dixon.

The Gas Committee of the Stockton Corporation have recommended the adoption of a carburetted water gas plant and buildings at a cost of £5000.

The death is announced of Mr. Donald Fraser, for many years goods manager for the Northern District of the North-Eastern Railway. He retired in 1892 after being fifty years in the company's service.

Messrs. Wm. Doxford and Sons, at Pallion-on-the-Wear, have just launched the twenty-fifth and largest steamer of the turret deck type yet built. She is for Messrs. A. R. Hansen and Co., Copenhagen, and her gross register is 3400 tons, net about 2190, and deadweight 5600 tons on 21ft. 8in. draught. Messrs. Doxford and Sons will supply the engines also, and they have adopted two of Babcock and Wilcox's patent water-tube boilers. It is believed that this is the first cargo steamer built for a foreign flag in which this type of boiler has been introduced.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE has been a rather better feeling in the pig iron market, although the amount of business done was not very large. Two weeks ago there was an impression that the market was about to go back owing to threatened labour troubles, and increasing stocks. The bears took advantage of this feeling to some extent, and prices fell away considerably, consumers having for the time evidently been well supplied with iron. A more hopeful view is now taken of business. Scotch warrants opened for the week at 46s. 7d., advancing to 46s. 9½d. The price was easier at 46s. 8d. afterwards, but evidences of a marked improvement in the finished iron trade sent up the price subsequently to 47s. 1d. cash. The demand for Scotch warrants was mainly for cash, and the price for one month was relatively lower than usual. Business was limited in Cleveland warrants, which was done at 37s. 5½d. to 37s. 6½d. cash. In Cumberland hematite there was a moderate business, mainly for one month, at 47s. 6d to 47s. 9d. The cash price was about 47s. 5d., and one lot was done for delivery in nine days at 47s. 6d.

The production of Scotch pig iron is maintained at the rate of last week. One furnace has been taken off ordinary iron, but an additional one has been placed on hematite. There are now 39 furnaces making ordinary, 39 hematite, and 3 basic iron, total 81, compared with 77 at this time last year.

Stocks of pig iron are on the increase, although there is as yet no reason to anticipate that the additions will in the meantime be inconveniently large. The increase in the past week to the stock in Glasgow warrant stores was 2340 tons, bringing up the total to 358,348 tons, compared with 282,361 at the end of May last year, thus showing an increase compared with that time of 76,000 tons. There is no certain means of ascertaining the condition of the stocks in makers' yards, as these are only reported at the end of the year, but the movement in the public stores is generally accepted as a fair indication as to what is taking place with regard to makers' stocks.

The prices of makers' pig iron have been steady, and are as follows:—Govan, Monkland, and Carnbroe, f.o.b. at Glasgow, Nos. 1, 47s. 6d.; Nos. 3, 46s.; Clyde, No. 1, 50s.; No. 3, 47s.; Summerlee, Calder, and Gartsherrie, Nos. 1, 50s. 6d.; Nos. 3, 48s.; Coltness, No. 1, 53s.; No. 3, 48s. 6d.; Glengarnock at Ardrossan, No. 1, 50s.; No. 3, 45s. 6d.; Eglinton, No. 1, 47s.; No. 3, 45s.; Dalmellington at Ayr, No. 1, 46s. 6d.; No. 3, 45s.; Shotts at Leith, No. 1, 52s.; No. 3, 48s. 6d.; Carron at Grangemouth, No. 1, 52s. 6d.; No. 3, 48s. 6d.

The shipments of pig iron from Scottish ports in the past week amounted to 5837 tons, compared with 7724 tons in the corresponding week of last year. There was shipped to Germany 440 tons, Holland 472, United States 10, Australia 75, India 316, Italy 170, Belgium 30, China and Japan 100, other countries 290, coastwise 3934, against 4704 in the same week of last year. For the first five months of the year the total shipments have been 126,153, compared with 133,644 in the same period of 1895. The foreign shipments during the five months have been 44,848 tons against 47,699 last year and the coastwise shipments 81,305, compared with 85,945 in the same time last year, there is thus a decrease both in the exports and in the coastwise shipments of Scotch pig iron. While the movement of ordinary Scotch pig iron has thus been rather falling off, there is reason to believe that the consumption of it at home has been well maintained, and there is no doubt that the quantity of hematite iron used by Scotch makers has materially increased. The imports of English iron at Grangemouth since the beginning of the year have been 187,912 tons, showing an increase of 33,873 tons over the quantity received the first five months of 1895.

The malleable iron trade is fairly busy, and the makers have at length seen their way to advance prices, establishing an increase of 5s. per ton. The steel works are very busy, chiefly with shipbuilding material. It is intimated that the Clydebridge Steel Company has received an order from the Government, and tenders for additional quantities of steel for the Admiralty are expected to be given out.

During May, 33 vessels with an aggregate tonnage of 22,470 were launched from the Clyde shipyards, with 27 vessels of 48,705 tons in May, 1895. The output of the five months now past comprises 101 vessels and 156,974 tons, against 92 vessels and 139,883 tons in the same period of last year. The month's output, as will have been noticed, is comparatively moderate, but that for the five months is larger than has been recorded for any corresponding period in the history of the trade.

A fair amount of new shipping has been placed in the past month, and a number of contracts are reported in the past few days. Messrs. Russell and Co., Port Glasgow, have received an order to build a steel twin-screw steamer for passenger and cargo service on the river Amazon. The Union Steamship Company of New Zealand has placed an order with Messrs. William Denny and Brothers, Dumbarton, for a fast steamer with extensive accommodation. The Fairfield Shipbuilding Company has contracted to build for the Isle of Man Steam Packet Company a paddle steamer which is intended to excel the best of the splendid vessels now running between Liverpool and the Isle of Man. This vessel will have accommodation for 2000 passengers. She will be 350ft. long and 42ft. wide, with engines of 10,000-horse power. Messrs. A. Stephen and Sons, of Glasgow, will build a screw steamer of 2800 tons gross for French owners.

The coal trade has not improved since last report, the total shipments from Scotch ports have been 152,779, against 167,647 in the preceding and 134,953 in the corresponding week last year. The five months' shipments, however, show an increase of 196,978 tons. While the current shipments are but moderate, it is gratifying to note that orders have been coming in rather more freely in Fifeshire, and business is fairly active in the West. Coal exports from the Clyde to the Mediterranean have fallen away, owing to a scarcity of ready tonnage; otherwise, there is no new feature in the trade. Main coal is quoted f.o.b. at Glasgow 5s. 9d.; splint, 6s. 3d. to 6s. 6d.; ell, 6s. 3d. to 6s. 9d.; steam, 7s. 6d. per ton.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THERE was a considerable falling off in coal shipments last week on account of the holidays, and in Cardiff especially coalowners, shippers, and the collective body interested on 'Change and elsewhere in the coal trade had to reflect on the important contrast between the week's totals and those of the preceding week. In round numbers the difference was 85,000 tons. One comment by a coalowner was pungent, "We pay heavily for the pleasure of our holidays." This is also very applicable to the monthly holiday of the colliers.

Newport totals were, of course, also affected, but Swansea recorded a despatch of 50,000 tons, or exactly 20,000 tons above the weekly average of coal and fuel. Amongst the Swansea items I note one—8260 tons anthracite for San Francisco.

This week the report from the Cardiff Exchange is on the whole favourable, though the old activity in business has not been quite regained. The inquiry for best and good seconds at last prices was fairly sustained, but drys are not selling well, and Monmouthshire coals are slack. Mid-week there was a little more buoyancy, and closing prices were as follows:—Best steam coal, Cardiff, 10s. 3d. to 10s. 6d.; best seconds, 9s. 9d. to 10s.; seconds, 9s. 3d. to 9s. 6d.; drys, 8s. 7½d. to 9s.; best Monmouthshire, 8s. 3d. to 8s. 6d.; seconds, 7s. 9d. to 8s.; best small, 4s. 9d.; seconds, 4s. to 4s. 6d.; drys from 3s. 6d.

The long prevalence of hot weather has not helped matters in the house coal trade, and only a moderate business is being done. Last prices, Cardiff, are:—Best house, 9s. 6d. to 10s.; No. 3 Rhondda, 9s. 6d.; brush, 7s. 6d. to 8s.; small, 6s. to 6s. 3d.; No. 2 Rhondda, 7s. 3d. to 7s. 9d.; through, 6s. to 6s. 3d.; small, 4s. to 4s. 3d. Swansea prices are:—Best anthracite, 11s. to 11s. 6d.; second quality, 9s. to 10s.; ordinary large, 8s. to 8s. 9d.; small rubble culm, 4s. to 4s. 6d.; steam, 9s. to 10s.; seconds, 8s. 3d. to 9s.; bunkers, 7s. 9d. to 9s., house coals, No. 3 Rhondda, 9s. 6d. to 10s.; No. 2 Rhondda, 8s. 6d. to 8s. 9d.; through, 6s. 6d. to 6s. 9d.; small, 5s. to 5s. 3d.; patent fuel, 9s. 9d. to 10s. 3d.; Cardiff quotations, 9s. 9d. to 10s. 3d.; coke, Cardiff, prices maintained; furnace, 13s. to 14s. 9d.; foundry, 15s. 6d. to 16s. 9d.; special, 19s. 6d. to 19s. 9d.; good demand.

The iron and steel reports of Swansea is encouraging. Pig iron has showed a slight advance upon the week, and the market continues firm, so that there is almost a certainty of better prices. One of the imports of the week took the form of 1550 tons of pig iron from Bilbao, while the consignments of ore have been unusually large. Dowlais received seven cargoes this week, Crawshay Bros. three, La Société Commerciale and Ebbw Vale one each. Reports from leading ironmasters are to the effect that rail orders in hand are sufficient to keep mills going for some time, and that an appreciable improvement is showing itself in bars.

One of the leading steel consignments of the week has been 800 steel billets from Newport for Riga.

The mid-week quotations, Swansea Exchange, were as follows:—Glasgow pig, 46s. 10½d., cash buyers; Middlesbrough, No. 3, 37s. 5½d.; hematites, 45s.; Welsh bars, £5 10s. to £5 12s. 6d.; iron plates, £6 to £6 17s. 6d.; steel plates, £6 to £6 17s. 6d.; Bessemer steel, bars, £3 17s. 6d.; Siemens, £3 18s. Steel rails, heavy sections, £4 10s. to £4 12s. 6d.; light, £5 10s. to £5 15s. Tin-plates, makers' quotations: Bessemer cokes, 9s. 3d. to 9s. 4½d.; Siemens' coke finish, 9s. 6d. to 10s.; ternes, 28 by 20, 16s. 6d., 17s. 6d., to 21s. 6d.; best charcoal, 12s. 9d. to 13s.; wasters, 6d. to 1s.; odd sizes, usual extras. Block tin, £59 17s. 6d. to £60 10s. Lead, English, £11 5s.; Spanish, £11 2s. 6d.

One of the excitements of the past week in the Cardiff district has been in the pitwood trade. Owing to the scarcity of tonnage, prices advanced from 15s. to 17s. per ton, and as contractors were unable to supply their mines, and had to look about in all quarters, those who held stocks did well. At the end of last week and the beginning of this cargoes began to put in an appearance—some heavy ones for Newport Pitwood Company—and the tendency now seems to be for prices to regain their normal condition. Present prices, 16s. 3d. Manganese ore is coming into Pyle from Coquimbo. North Walian tracts only feebly worked so far.

In tin plates there has been a little more doing, and last week's shipments being heavier than usual helped to lessen stocks. Makers are looking at the situation thoughtfully, for, as remarked on 'Change, Swansea, this week, only a hand-to-mouth business is being done, and prices are such that there is little or no profit to be made. Yet, in various quarters, movements show that mills which have been laid by are going to start, and the result must soon be critical again.

Distress prevails in the Cwmfelin district on account of stoppage, and a fund is to be opened.

At Ely Tin-plate Mills, Llantrissant, men have agreed to accept a reduction of 25 per cent., and two mills will be started.

Swansea works are fairly well employed, but there is a scarcity of orders for forward delivery.

In the Briton Ferry district last week eighteen mills were at work, and business in that quarter is tolerably brisk, both in tinplate and steel bar. Cyfarthfa is also turning out more tin bar of late.

Cardiff prices for ore, which is in good demand, is as follows:—Best Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d.; Garucha, 10s. 9d. to 11s.

A visitor from Wales to Bilbao reports favourably of the condition of things there. In the North there is still ample supply, but the question is will quality depreciate in further working? As regards the South, yield is practically inexhaustible.

The drought of to-day over the mining districts began this week to awaken apprehension in more than one quarter, and local authorities have been closely investigating at the chief towns, and calculating possibilities. At Aberdare, the Rhondda Valley, Swansea, Merthyr, and Cardiff, water is the prominent theme, and I shall fully expect that the outcome will be strenuous efforts in the future to get different reservoir requirements where the investigation has found them lacking. Cardiff is well placed, but there has been a scare on account of insufficient ventilation in some of the storages. Newport is fairly well off. Aberdare is on a very short supply. Ogmore Valley is well supplied. Given ample engineering outlay in the hill districts, and the last report should be made to apply to all.

As anticipated, the Bute Dock new issue was applied for more than three times over. A large request was made by Cardiff alone, so that many are disappointed. Probably more ventures are in the near future.

I see that the new issue of Davis and Sons, Ferndale, is the subject of a good deal of speculation. The addition of Tylerstown collieries probably causes this, as a much longer duration of output is certain; but authorities state that in all probability the new issue will be taken up by the present shareholders of the company.

Taff Vale ordinary shares have advanced to 95¾. Port Talbot a fraction less than last quotation.

I much regret to announce the death of Inspector Cunningham, of the Brecon Railway, an able railway official, for more than thirty years connected with this well-managed line.

I see that the Brecon and Cambrian Railway authorities are arranging the royal programme, necessary by the visit of the Prince of Wales to Aberystwith and Cardiff. The locomotives are to be, from what I hear, marvels of decorative art, as well as of excellence.

The Cambrian Railways, and Brecon and Merthyr, are to make a record season, if prospects hold good. It is opening well.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

OWING to the holidays few large purchases have been made during the past week, and business on the iron market has consequently been a shade quieter.

A healthy tone characterises the Silesian iron trade, and there is good reason to expect a further increase in the employment of the different branches, the general movement being decidedly in an upward direction.

In Austria-Hungary the blast furnace works, as well as the rolling mills, have continued in fair activity. Heavy contracts are comparatively scarce, but small orders, especially for home consumption, are plentiful. Nearly all the branches of the building and engineering line are very busy, and in the railway department good employment is secured till September. It appears that since the beginning of last year the locomotive factories have been uncommonly active. In 1895 no less than 180 locomotives were built, against 100 in the year before; among these thirteen were small truck locomotives.

In France the iron and steel producing establishments have been, on the whole, in satisfactory occupation. The works of Alais have secured an order for 31,000 steel rails for the Paris-Lyons Railway at 140f. p.t., while the steel works in Longwy have booked a contract for 2000 steel rails at the same price for the East Railway. Both makers and manufacturers are entertaining fair hopes with regard to future employment, as June promises to be a very busy month.

There is not much of interest to be related this week in connection with the iron trade in Belgium, holiday influences having naturally been felt in nearly all departments. Satisfactory reports are, on the whole, given with regard to the business that is done on home account, both demand and prices being good, but foreign orders, though willingly accepted at quotations that are often considerably lower than those officially quoted, continue to be very scarce. Especially plates remain extremely dull. Belgium import and export during the first quarter of the present year has been as under:

	Import.		Export.	
	1896. Tons.	1895. Tons.	1896. Tons.	1895. Tons.
Iron ore	468,467	441,252	80,447	54,862
Raw cast steel	3,048	—	46	—
Ingots	2,822	—	—	—
Billets and plates	1,363	—	—	—
Steel wire	1,612	1,048	502	154
Steel girders	98	115	10,105	8,472
Steel rails	196	37	19,239	11,365
Sheets	22	—	2,303	—
Bars	2,702	2,106	6,894	5,400
Nails	—	2	2,303	1,012
Steel manufactured goods	226	492	4,885	5,564
Raw cast iron	94,092	—	3,999	—
Manufactured cast iron	832	186	5,087	8,473
Scrap iron	13,857	3,668	6,502	2,063
Iron rails	797	—	13	—

Hardware	1,259	1,003	7,182	6,3 7
Tin sheets	933	—	118	—
Rolling material	61	360	6,268	6,588
Machines	5,521	4,132	7,971	5,151

On the Rhenish-Westphalian iron market general demand has been good, and prices are very firm all round. The pig iron trade is briskly employed in almost all departments, and most satisfactory reports are received with regard to the number of contracts that have been booked, many works having already disposed of their output till the end of the present year. The malleable iron industry maintains a very firm appearance; it is generally felt that as the year advances business increases also. This is particularly the case with bars, which have been improving slowly but steadily ever since the upward movement in trade began. There is likewise a considerable weight of business doing in girders, as well as in plates and sheets. The wire trade is also progressing favourably, and rivets have been fetching decidedly better prices of late. The engineering industries have been fully engaged, and new work continues to come in freely.

Total output of pig iron in Germany, including Luxemburg, was, for April of present year, 538,396 t.; of which 148,241 t. were forge pig and spiegeleisen, 44,259 t. Bessemer, 264,805 t. basic, and 81,091 t. foundry pig. Production in April, 1895, amounted to 470,420 t.; in March, 1896, it was 551,157 t. From January 1st to April 30th, 1896, no less than 2,058,751 t. were produced, against 1,875,843 t. during the corresponding period the year before.

According to statements published by one of the leading Belgian iron and steel companies, the average pay of their men amounts to M. 776 per head per annum, while the Rhenish-Westphalian machine and hardware industries report the yearly wages of their men to be M. 921 per head. The average pay of a French miner has been officially stated to amount to 1181f. per annum, daily wages being about 4·14f. per head.

Very satisfactory reports have recently been received with regard to the iron business in Sweden; shipments for March and April have been uncommonly large, owing to a specially brisk trade in manufactured iron. As the majority of the works have sold their summer output, contracts for autumn deliveries can only be accepted at advanced prices. During the first three months of the present year there were exported from Sweden 5895 t. pig iron, against 3791 t. in the year before; 568 t. castings, against 174 t.; 2601 t. raw bars, against 1262 t.; 27,239 t. finished bars, against 19,600 t.; 188 t. scrap iron, against 185 t.; 390 t. iron wire rods, against 356 t.; 609 t. iron plates, against 534 t.; 52 t. wire, against 49 t.; 561 t. nails, against 521 t.; totals amounting to 38,067 t., against 26,382 t. for the corresponding period the year before. Exports in iron ore were 73,322 t., or 53,000 t. more than during the same period last year.

A FLEET of steel canal boats of the Cleveland Steel Canal-boat Company arrived in New York on May 13th. It consisted of one steam barge with five consorts, all loaded to a draught of 5ft., which is the maximum now practicable in the Erie Canal. The fleet left Cleveland on May 3rd at 1 a.m., arrived at Buffalo May 4th at 8 a.m., left Buffalo May 4th at 6 p.m., arrived at New York May 13th at 8 a.m.; lost 10 hours at Buffalo on account of ice in the harbour, 4 hours at Brockport cleaning fires, 4 hours at Troy waiting for teams through single locks; total, 18 hours lost time. Actual running time from Cleveland to New York, 9 days 13 hours; Cleveland to Buffalo, 31 hours; Buffalo to Troy, 5 days 20 hours; Buffalo to New York, 7 days 12 hours. The cargo included 653,000 lb. of nails for export to Japan; 375,000ft. of lumber for New York; 10 tons paraffin wax for Germany, and a miscellaneous cargo for New York. *Engineering News* says the west-bound cargo will consist chiefly of sugar for Detroit, Toledo, Cleveland, and the south-west.

11,227. Stop Valves for Gas and Steam, C. Wehner, London.
11,228. Velocipedes, W. Welford, London.
11,229. Actuating Stamping Machines, W. E. Downs and H. J. Scott, London.
11,230. Electrical Regulating Apparatus, H. Pieper fils, London.
11,231. Tool Bag or Wallet for Cycles, E. Labenz, London.
11,232. Current Conducting Apparatus, C. F. P. Stendebach and O. H. Linker, London.

23rd May, 1896.

11,233. Working Signals, Hurst, Nelson, and Co., Ld., and G. T. Wheatley, Glasgow.
11,234. Apparatus for Carrying Glass, J. J. Spear, Portsmouth.
11,235. Driving Mechanism for Vehicles, E. B. Fenby, Birmingham.
11,236. System of Sewer Ventilation, S. S. Allin, London.
11,237. Portable Poultry Houses, H. J. F. Rose, Dunstable.
11,238. Mud Scraper for Brushes, R. T. Hewlett, London.
11,239. Governing Engines, J. Maxton and A. L. Jones, Belfast.
11,240. Controlling the Legs of Step Ladders, E. Hart, Bristol.
11,241. Rust Preventer, W. Preston and F. D. Docker, Birmingham.
11,242. Cement, J. Walker, Derby.
11,243. Purifying Sewage, E. W. T. Jones and J. Garfield, Wolverhampton.
11,244. Weight Indicators for Carts, J. H. Butler, Wolverhampton.
11,245. Galvanising Metal Sheets, Davies Brothers and Co., E. A. Davies, and S. T. Thomas, Wolverhampton.
11,246. Tumbler Glasses, A. Walker, Halifax.
11,247. Traction Engines and Motor Cars, O. Thom, Manchester.
11,248. Pipe Flanges, F. A. Jones and J. Constabie, Birmingham.
11,249. Electric Car Driving Apparatus, W. Griffin, Halifax.
11,250. Pipe Vices, F. Bosshardt.—(*Blau and Co., Austria.*)
11,251. Cycle Tire, R. N. Redmayne, Newcastle-on-Tyne.
11,252. Tires, R. R. Gubbins, London.
11,253. Mud Guards for Cycles and Vehicles, T. Ellis, Nottingham.
11,254. Sounding Board, C. F. and K. Stahlecker, London.
11,255. Cycle, &c., Tires, T. Chappell and H. Smith, Sheffield.
11,256. Brakes for Bicycles and Tricycles, W. Tapp, Bristol.
11,257. Driving Fibres into the Pins of Circular Combs, H. R. Wickins, F. L. Speight, and J. H. Exley, Bradford.
11,258. Stacking Hay, C. Grieves and J. H. Davies, Bristol.
11,259. Ball-bearing Nest for Axles, R. F. Hall, Birmingham.
11,260. Machinery for Manufacturing Seamless Steel Tubes, R. F. Hall, F. Warwick, and T. Smith, Birmingham.
11,261. Distributor for Agricultural Purposes, T. C. Sargeant, Northampton.
11,262. Artificial Light Photography, C. E. Elliott, London.
11,263. Applying and Removing Tires, A. A. Vérel, Glasgow.
11,264. Ball Pneumatic Tire for Cycles, A. Pardon, London.
11,265. Fasteners for Ladies' Waist Belts, W. Pearce, Birmingham.
11,266. Tires for Cycles and Vehicles, A. A. Vérel, Glasgow.
11,267. Producing Acetylene Gas, T. Thorp and T. G. Marsh, Manchester.
11,268. Producing Acetylene Gas, T. Thorp and T. G. Marsh, Birmingham.
11,269. Charging Gas Generators, T. Thorp and T. G. Marsh, Manchester.
11,270. Cycle Handle, J. F. Phillips and A. E. Pennington, Leigh.
11,271. Pneumatic Tires, W. Turner, London.
11,272. Unicycles, C. T. Craig, London.
11,273. Pneumatic Tires, A. Norreys, London.
11,274. Knitting Machines, W. Buckler, D. Routledge and Co., and O. Kerr, London.
11,275. Smokeless Gunpowder, T. Hawkins, J. W. Carr, and A. Wellby, London.
11,276. Pedal Cranks for Velocipedes, M. Ryan, London.
11,277. Forced Draught Apparatus, J. K. Broadbent, Manchester.
11,278. Lawn Tennis, &c., Nets, T. P. Howard, Manchester.
11,279. Heating Boilers and Furnaces, S. Pointon, Manchester.
11,280. Register, &c., Fire-grates, S. Pointon, Manchester.
11,281. Looms, R. L. Hattersley and S. Jackson, Bradford.
11,282. Cotton Carding Machinery, T. R. Marsden, Manchester.
11,283. Cotton Carding Machinery, T. R. Marsden, Manchester.
11,284. Instantaneous Steam Generators, J. H. Knight, Farnham.
11,285. Cycle Gear Cleaner, J. Wilcock and A. Bradley, Manchester.
11,286. Excavating Machinery, E. B. Butler and J. Pearson, London.
11,287. Puncture Proof Shield, I. Hayes, Runcorn, Cheshire.
11,288. Method of Advertising in Railway Lavatories, F. J. Caygill and J. Stephenson, Newcastle-on-Tyne.
11,289. Inflating Tires, W. and J. R. Brocklebank, Manchester.
11,290. Making Tires for Cycles, &c., J. C. B. Taylor, Bath.
11,291. Boat Propelling Apparatus, A. G. Ramage, Leith.
11,292. Valves, J. H. Carruthers and H. Brier, Glasgow.
11,293. Feed-water Heaters, Babcock and Wilcox, Ld., and W. Reavell, Glasgow.
11,294. Adjustable Wrench, T. Armstrong and J. Frankling, London.
11,295. Joint for Pipes and Tubes, G. M. Bowen, Birmingham.
11,296. Artificial Limbs, S. D. Leeper, Liverpool.
11,297. Block for Manipulaling Butter, E. Jones, Birmingham.
11,298. Wheels for Cycles and Carriages, J. Hamblet, London.
11,299. Rims and Tires of Cycles, &c., J. Barclay, London.
11,300. Brush for Fastening Revoluble Brushes to their Spindles, L. Bradshaw and C. Whitfield, London.
1 ,301. Coiled Tubular Boilers, E. N. Beszant and The Swiftsure Safety Kitchen Boiler Company, Liverpool.
11,302. Drains and Sewers and Pipes, A. Whittaker, London.
11,303. Linoleum and Floor Covering, W. Oppenheimer, London.
11,304. Wheels, J. Favets, London.
11,305. Tires, S. Pattisson, London.
11,306. Photograph Developing Solution, J. Hauff, London.
11,307. Gas Engines, J. Doy, London.
11,308. Finishing Type, T. W. Smith and R. Chitson, London.
11,309. Colouring Matters, Read, Holliday, and Sons, Ld., and H. Dean, London.
11,310. Brakes, W. C. and J. H. Punchard, and W. and I. Darby, London.
11,311. Pads for Polishing Purposes, &c., D. Scott, London.
11,312. Night Light Cases, G. C. and M. B. Fowler, London.
11,313. Vaporising Burners, A. J. Boult.—(*G. Bartel, Germany.*)
11,314. Steering Gear for Bicycles, J. Monteith, London.
11,315. Bogies for Railway Vehicles, I. A. Timmis, London.
11,316. Window and Skylight Blind, A. J. B. Squire, London.
11,317. Tins for Preserved Milk, &c., J. W. Palmer, London.
11,318. Locks, R. Friberg, London.
11,319. Studs, Links, &c., G. Caryl and T. H. Hooper, London.
11,320. Electric Railway Signals, W. M. Klees, London.
11,321. Cooling Water, D. Halpin, J. B. Alliott, and L. Sterne, London.
11,322. Mattresses, &c., O. Imray.—(*C. S. Hurd, France.*)
11,323. Apparatus for Serrating Materials, E. C. Blackett, London.
11,324. Velocipede and other Saddles, J. F. Rees, London.
11,325. Machine for Pointing Pencils, K. Pintz, London.
11,326. Manufacture of Cyanides, E. A. and J. F. C. Williams, London.
11,327. Heating Retort, E. A. and J. F. C. Williams, London.
11,328. White Lead, D. Urquhart and J. M. Small.—(*L. H. Despeissis, France.*)
11,329. Surgical Needles, W. D Calvert and W. C. Weight, London.
11,330. Tires, A. A. Furst, London.
11,331. Improved Pneumatic Tires, H. A. Couchman, London.
11,332. Inflatable Tire for Cycles, M. A. Wier, London.
11,333. Chains, M. A. Weir, London.
11,334. Inflatable Horse Collars, W. J. Coupland, London.
11,335. Appliances for Driving Cycles, J. J. Rathbone, London.
11,336. Ball Bearings, W. R. Smith, London.
11,337. Musical Instruments, W. Heilbrunn and S. Blüth, London.
11,338. Electrodes for Electrolytic Purposes, E. A. G. Street, London.
11,339. Gas Lamps, T. Gordon and W. R. Swift, London.
11,340. Clutches, I. Björnstad and E. Anderson and Goolden, Ltd., London.
11,341. Vehicles, C. A. Faure, London.
11,342. Vehicles, C. A. Faure, London.
11,343. Fasteners for Belts, H. T. How and W. Pearce, Birmingham.
11,344. Elastic Tires for Wheels, W. H. Trimble, London.
11,345. Apparatus for Mixing Liquids, A. Gates, London.
11,346. Stacking Apparatus, O. E. Adolph, London.
11,347. Hydrocarbon Motors, E. Wiseman and J. Holroyd, London.
11,348. Spring Hooks, H. W. Ley and A. G. Bagot, London.
11,349. Cyclometers, R. M. Marples.—(*Seth Thomas Clock Company, United States.*)
11,350. Incandescent Mantles for Gas Lamps, J. H. H. Duncan and D. W. Sugg, London.

26th May, 1896.

11,351. Rotary Engines, W. Hayward, London.
11,352. Non-collapsible Tires for Cycles, W. Pennington, Belfast.
11,353. Supplying Cotton to Scutchers, W. J. Orr and S. Walmsley, Manchester.
11,354. Automatic Game and Pheasant Stop, R. T. H. Somerset, Monmouthshire.
11,355. Pneumatic Tires of Cycles, F. Richmond, Burnley.
11,356. Brake Mechanism for Velocipedes, A. Munro, Glasgow.
11,357. Manufacture of Drive Chain, J. C. Rollason, Birmingham.
11,358 Flexible Tires, M. J. Adams, Leeds.
11,359. Garden Tent, W. S. Coppin, London.
11,360. Construction of Pneumatic Tires, I. Lenehan, Dublin.
11,361. Mowing and Reaping Machines, T. Eddleston, Blackburn.
11,362. Cycles, W. A. Comber, Ilfracombe.
11,363. Appliances for Lubricating Axles, T. Cook, Sheffield.
11,364. Purification of Syrups, J. D. Scott and A. Smith, Glasgow.
11,365. Combined Envelope and Blank Letter, E. W. Margetts, Stourbridge.
11,366. Direct Acting Steam Pumps, &c., J. Weir, Glasgow.
11,367. Springs for Wheeled Vehicles, G. Johnston, Glasgow.
11,368. Chairs, J. Davies, London.
11,369. Boring Holes, J. and W. Jones, Halifax.
11,370. Production of Colouring Matters, Read, Holliday, and Sons, and J. and J. Turner, London.
11,371. Scouring Wool, W. R. Jones.—(*T. A. Jones and D. Gibb, Australia.*)
11,372. Water-closets, J. Shanks.—(*T. van Heemstede Obelt, Holland.*)
11,373. Bracket for Lamps, W. J. Ward, Newcastle-on-Tyne.
11,374. Tires for Cycles, J. N. Peake, Longport, Staffordshire.
11,375. Rims of Wheels of Cycles, J. A. Williamson, Glasgow.
11,376. Driving Mechanism for Cycles, A. M. Arter, London.
11,377. Shape of Pneumatic Tires, J. A. Hennessy, Limerick.
11,378. Wheel Rim for Cycles, W. D. Mastaglio, Newcastle-on-Tyne.
11,379. Head Lock for Cycles, A. T. Blood, Huntingdonshire.
11,380. Securing the Cords of Window Sashes, J. Gibson, Glasgow.
11,381. Machine for Basting Meat, A. C. Hall and J. Malcolm, Glasgow.
11,382. Keyless Money Box, R. Hird and J. Underwood, Barrow-in-Furness.
11,383. Construction of Cycles, P. Bendall, Cheltenham.
11,384. Chimney Pots, G. W. Taylor, Rawtenstall, Lancs.
11,385. Cocks for Regulating Gas Lights, J. E. Rogers, Birmingham.
11,386. Sectional Water-tube Boilers, H. McIntyre, Glasgow.
11,387. Railway Signal Apparatus, A. G. Horne, Glasgow.
11,388. Covers for Books and Albums, A. Martyn, London.
11,389. Process of Beating, &c., Syrup, J. Werner, London.
11,390. Marking Sheep, H. W. Potter and S. Frankel, London.
11,391. Cut-outs for Electrical Uses, J. C. Reynolds, Wolverhampton.
11,392. Fastening for Down-spouts, E. T., L., and E. Fletcher, Wigan.
11,393. Road Locomotives, &c., J. G. Inshaw, Birmingham.
11,394. Lasting Clog Uppers, E. Lee, London.
11,395. Pneumatic Tires, P. A. Horrocks, London.
11,396. Ore Crushing Machinery, G. Bowman, London.
11,397. Finishing Inlaid Linoleums, W. G. Thomson, London.
11,398. Lifting Jacks, W. C. Crawford, London.
11,399. Tramcar Fenders, P. Jones, London.
11,400. Two-wheeled Vehicle Brake, M. J. Oliver, Cornwall.
11,401. Valve for Pneumatic Tires, T. J. Harris, Birmingham.
11,402. Sprocket Wheel, H. L. Todd and F. W. McClellan, London.
11,403. India-rubber Mats, &c., W. C. Cunningham, Preston.
11,404. Gear Cases, W. H. Corker and S. J. and E Fellows, Ld., Birmingham.
11,405. Handle Bars for Bicycles, G. A. Phillips Birmingham.
11,406. Securing Tires to Rims of Wheels, J. Adair, Waterford.
11,407. Toy, J. Savreux, Brussels.
11,408. Lubricating Stuffing-boxes, J. B. Davis, London.
11,409. Rotary Boot Trimming Machine, A. S. Vose, London.
11,410. Trimming and Randing Boots, A. S. Vose, London.
11,411. Construction of Gas Pendants, G. F. Ostins, London.
11,412. Scarves, I. Boyd, Lanark.
11,413. Telephones, J. C. Chalmers, Glasgow.
11,414. Signalling Apparatus, J. F. Barker, Glasgow.
11,415. Apparatus for Cleaning Ships, P. Reilly, London.
11,416. Lubricators, J. J. Kennedy, London.
11,417. Connecting Rails, R. C. Brown and F. E. Huntress, London.
11,418. Stop Valve for Gases, &c., O. Brunler, Berlin.
11,419. Lighting Lamps, H. D. Fitzpatrick.—(*The Empire Self-Lighting Oil Lamp Company, United States.*)
11,420. Motive Power Engines, J. Lewthwaite, London.
11,421. Dynamos and Electromotors, J. D. F. Andrews, London.
11,422. Propelling Boats, &c., J. and J. B. Swallow, London.
11,423. Elastic Tires for Velocipedes, W. Carter, London.
11,424. Aerial Machines, R. Wesch, London.
11,425. Adjustable Partitions for Drawers, L. Conant, London.
11,426. Saddles for Bicycles and Tricycles, P. Turner, London.
11,427. Twisting and Winding Yarns, Count C. de Rossetti, London.
11,428. Cooking Eggs, F. E. V. Baines, London.
11,429. Electric Brakes, The British Thomson-Houston Company, Ltd.—(*W. B. Potter, United States.*)
11,430 Pumps for Pneumatic Tires, &c., W. Cross, London.
11,431. Tires for Velocipedes, &c., H. W. Tyler, London.
11,432 Steering Handle for Velocipedes, C. Farmer, London.
11,433 Regenerative Gas Furnaces, F. Siemens, London.
11,434. Automatically Closing Door, A. B. von der Ropp, London.
11,435. Springs for Saddles, &c., F. J. Esmond, London.
11,436 Cycles, T. Watson, London
11,437. Gasogenes, J. C. Mewburn.—(*H. Carrière and A. Vazou, France*.)
11,438. Prismatic Piston Valve, J. J. Campbell, London.
11,439. Portable Apparatus for Writing, J. Pool, London.
11,440. Antiseptic Cleansing Device, M. Frisch, London.
11,441. Electric Arc Lamps, T. E. Adams, London.
11,442. Steam Engines, A. Hoe, London.
11,443. Cocks, Faucets, and other Valves, W. Heston, London.
11,444. Combined Weight and Cost Indicating Apparatus for Spring Balance Scales, &c., The Combined Weight and Cost Indicating Scale Company, Limited, H. J. Wood, and W. Thomson, London.
11,445. Toy Pumps, J. T. Lawrence, London.
11,446. Boxes for Transporting Butter, &c., G. Pontin and Pontin's Patent Butter Box Company, London.
11,447. Lambs' Wool or Slipper Sole, S. Borchardt, London.
11,448. Barrel Machine, W. T. Vale and A. Buntin, London.
11,449. Producing Lithographs, W. G. Rochester and S. E. la Ronde, London.

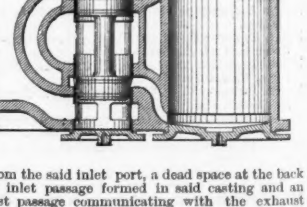
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

555,508. Steam Locomotive, *W. P. Henszey, Philadelphia, Pa.—Filed November 15th*, 1895.

Claim.—The combination in a locomotive cylinder, of the casting having a cylindrical valve chest, a central inlet port for live steam, exhaust ports at each end of the valve chest and ports leading to the cylinder mid-way between the inlet port and exhaust ports, a central inlet passage formed in said casting and extending from the said inlet port, a dead space at the back of the inlet passage formed in said casting and an exhaust passage communicating with the exhaust ports and situated back of the dead space so that the steam inlet passage is separated from the exhaust passage, substantially as described.

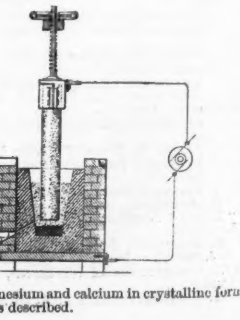
555.508



555,796. Compound of Magnesium, Calcium, and Carbide, *C. Whitehead, Washington, D.C.—Filed December 30th*, 1895.

Claim.—(1) The double carbide of magnesium and calcium, substantially as described. (2) The double carbide of magnesium and calcium in crystalline form substantially as described.

555.796



THE NATIONAL ELECTRICAL EXHIBITION AT NEW YORK.

The Electrical Exhibition held at New York during the month of May, 1896, under the auspices of the National Electric Light Association, was large and successful. More than this, it included some of the latest important applications of electricity, and was fairly representative of the various scientific and commercial applications of electricity, with one important exception. This exception was the electric railway, the exhibits in this department being confined to a couple of truck frames for electric cars, one or two electric rail bonds, and some line fittings. This deficiency of the Exhibition was particularly surprising and regrettable, in view of the great extent of electric railways and the great amount of money and inventive skill expended in their equipment and improvement. There was a very complete historical exhibit, and the popular interest was catered for by the exhibits of Roentgen ray phenomena, vacuum tube lighting, &c., and by conveying the "roar of Niagara" by telephone. To persons who have heard the steady pulsating roar of the great cataract this was very interesting. The receiver was placed at the foot of the American fall, being shielded from the flying spray.

The display of lamps was very large, ranging from the tiny bulbs used in dentistry and surgical work for illuminating the interior of the mouth, throat, or other organs, to the various sizes and styles of incandescent lamps for ordinary lighting and decorative purposes, and the large arc lamps for street lighting. Many of these latter had opal or clouded globes entirely enclosing the carbon and apparatus, preventing the unpleasant and dazzling effect of the arc, and burning very steadily. The Brush Electric Company showed three of its old machines as matter of interest. The first was the first Brush arc dynamo which was sold in 1877, and used steadily for twelve years. The second was a 16-light 2000-candle power arc dynamo, which was run by the Fulton Worsted Mills from September 1st, 1879, to April 10th, 1892; and the third was a 40-light dynamo operated by the Berkeley Mill Company from December 1st, 1881, to May 19th, 1893. These two latter machines were bought from the users by the Brush Company to be exhibited at the Chicago Exhibition of 1893, and they were exhibited at New York just as they left the factory. This company's working exhibit included arc dynamos of 80, 100, and 125-light dynamos, and double arc lamps. The 80-light dynamo was connected direct to a 60-kilowatt 220-volt motor, the machine running with its load of eighty lights—of 2000-candle power—with a difference of potential not exceeding 1500 volts between any part of the machine or circuits, the machine maintaining its automatic regulation. In other words, it is a division of an internal and an external circuit of an arc dynamo into three circuits, with a difference of potential not exceeding one-third of the total load on the dynamo. These three circuits were run direct from the terminals of the dynamo, and on any one of these circuits the voltage will not exceed 1500 volts, or on which there will not be more than twenty-seven lights. The circuits may be run from the switchboard, and can be thrown together in any combination if desired. The greatest potential around the dynamo or circuit will be that of the greatest circuit. The dynamo will run its full capacity with any distribution of load on the different circuits. Three-fourths of the load may be run on any one circuit, and one-fourth divided up between the other two, or all the load may be run on any one circuit. The advantages claimed are the flexibility of handling the circuits, the reduction of high voltages on circuits run from large dynamos, and the use of large units with corresponding increase in efficiency, saving in floor space, belting, &c.

The Edison Electric Illuminating Company showed the Van Vleek edgewise regulating system, with dynamo switches, regulators, ampère meters, volt meters, and controlling apparatus feeder. Current for this exhibit was supplied to the feeder switchboard from the company's street mains and from a storage battery, illustrating the use of such batteries in Edison stations. From the switchboard the current passed through a feeder tube—as used in the streets—to a feeder box, thence to a distributing box and a street main to a service box such as placed on a consumer's premises. Next to the feeder box was a new controllable box by which a tie-feeder can be divided from the station into distributing feeders. From the service box the current was carried through on Edison chemical meter—as usually placed on the consumer's premises—and a Thomson-Watt meter, and was then distributed as it would be in a house, showing its practical application for heating rooms, lighting, cooking, running sewing machines and dental machinery, &c. This company has now six stations in New York—one of which has generators of 800 kilowatts—supplying 6000 customers, with about 300,000 incandescent lamps, 3700 arc lamps, and 15,000-horse power for power and miscellaneous purposes. The company also showed two of its double-light ornamental poles, with Edison-Bowker lamps, as used in Fifth Avenue.

The General Electric Company exhibited, among other things, the Thomson constant potential arc lamps for direct current incandescent, power and railway, and alternating current incandescent circuits. The direct current lamps for incandescent circuits are run two in series on nominal 110-volt circuits. The standard current is 9 ampères with 44 volts at the arc. The extra voltage is taken up by a resistance which is placed in series with the arcs. Lamps are made for 4, 5, or 7 ampères, or any current up to 20 ampères. The railway lamp is intended for use on direct current power and railway circuits, and the number of lamps to be placed in series depends on the minimum potential of the line for any considerable time at the point where branch is taken off. With the carbons furnished, each lamp with its proportional part of resistance takes 50 volts; therefore, ten lamps can be run from a circuit whose minimum potential is 500 volts, and four lamps from a 220-volt circuit. An adjustable rheostat is placed in each series of lamps. Each railway lamp is provided with an automatic cut-out to prevent breaking the 500-volt current, should the carbons be burned short or the arc extinguished from any cause. The cut-out, in operating, substitutes for the arc a resistance which is carried on the chimney, and which assists in preventing an excess of current. Not more than two lamps out of ten, however, should be out at the same time, for in this case the current will unduly increase and the waste energy become excessive. A prominent feature claimed for this lamp is its ability to operate satisfactorily during considerable changes of potential on the line.

The alternating current lamp is placed directly on the transformer or compensator circuit, and under normal conditions no extra resistance is included in the circuit. The feeding mechanism is regulated wholly by the main current, and there are no potential coils. All of these lamps are made either plain or ornamental in various styles and sizes.

The applications of power were numerous and varied. including pumps, fans, heavy machine tools, passenger elevators—or lifts—printing presses, &c. The Niles Tool Works showed drilling and planing machines, and special machine tools for street railway repair and construction shops, all operated by electric motors mounted on frames. The Crocker-Wheeler Electric Company, which employs electric motors for driving all its tools and machinery—as described in The Engineer—included an electric hoisting engine in its exhibit. Pumps driven by electric motors were shown by the General Electric Company—using a Knowles pump—and by the Worthington and Goulds Pump Manufacturing Companies. The Goulds Pump Manufacturing Company has at Canandargna two triplex pumps of 1,000,000 gallons daily capacity, each driven by an induction motor of 100-horse power, using the three-phase system over a transmission of 3½ miles. It has also supplied an electric pumping plant for the waterworks of De Kalb and Memphis, the latter having a daily capacity of 500,000 gallons. Smaller pumps are used in mines, office buildings, &c.

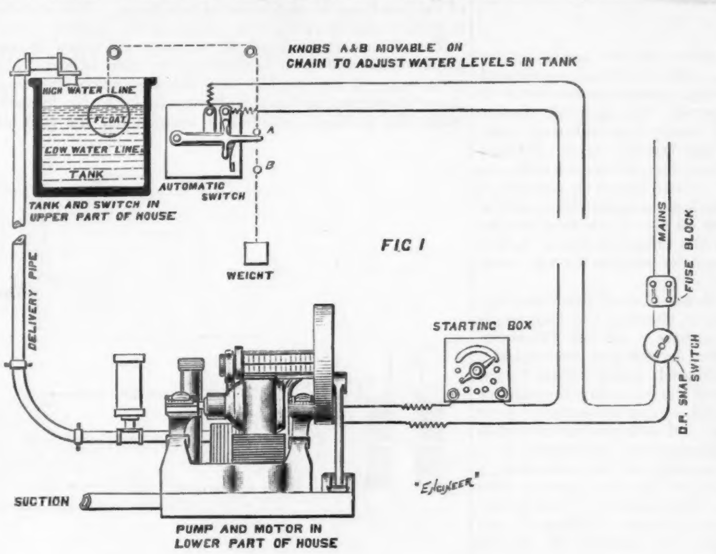


FIG I

The Worthington electric pump is specially intended to supply the reservoir tanks of high office buildings or residences, where the pressure carried on the city main is not sufficient to elevate water above the lower stories. It is made in two sizes of 250 and 500 gallons capacity per hour respectively, has a limited number of working parts, and requires little or no attention when once installed. A special feature is the absence of gears, the motor being connected to the pump entirely by belt, thus avoiding the noise usually caused by gearing. The plunger is differential, displacing equal quantities of water on both the up and the down stroke; and as the normal speed of the pump shaft is 200 revolutions per minute, the result is an even and regular flow of water through the discharge pipe. Another advantage of the differential plunger is that it equalises the work, throwing a constant load on the motor. The actual amount of power consumed varies between ½-horse power and 1-horse power, depending upon the head pumped against. The diagram—Fig. 1—shows the method of wiring the motor, and an automatic controlling device for stopping and starting the pump. This arrangement insures a supply of water always ready for immediate use. The operation, briefly described, is as follows. A regular hand rheostat is placed in the main circuit, one wire being first led through a snap switch located in some convenient place near the tank. Suppose the pump to be running delivering water into the tank, the float rises until the knob A comes in contact with the lever of the switch, when the suspended weight snaps it open, breaking the circuit and stopping the pump; when the float descends, owing to water being drawn from the tank, the knob B comes in contact with the lever, closing the switch and again starting the pump. By adjusting A and B, any desired water level may be maintained. Worthington pumps suitable for all services are built to be driven by electric motors; and special designs have been made to cover the requirements of hydraulic elevator service, mine service, waterworks supply, irrigation purposes, fire protection, or, in short, any service where electric motive power can be used to advantage.

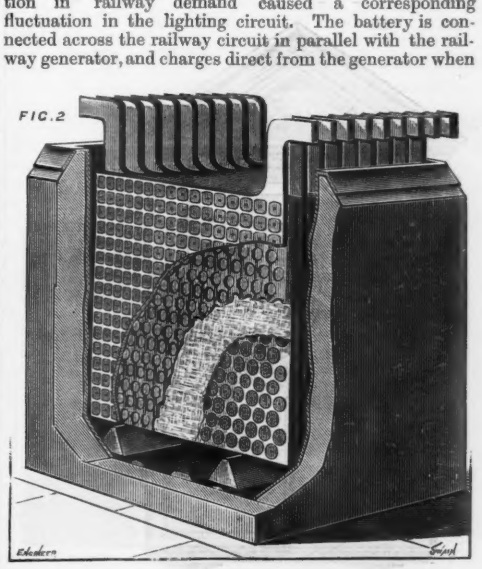
The development and introduction of storage batteries has been greatly hindered by litigation over the various patents, but within the past few years the Electric Storage Battery Company has acquired the patents and patent rights formerly owned and controlled by some twelve companies, and now has the sole right to supply in the United States storage batteries of all the important types, which enables it to supply the type of battery best suited to individual cases. This company is the sole manufacturer of the chloride accumulator, which has been largely introduced for large installations in power plants, and has also been applied for motor carriages and yachts. The company exhibited a handsome launch fitted with batteries supplying current for a little motor under the floor, which drives the screw. It also exhibited a four-wheel carriage on the Morris and Salom system, which has been described by The Engineer in connection with the Chicago competitive runs last year.

In regard to the application of storage batteries at central power stations, it may be noted that the Twelfth-street station of the Edison Electric Illuminating Company has a battery of 150 cells of 4000 ampère hours capacity, installed 75 on each side of the three-wire system, giving a total capacity of 8000 ampère hours at 130 to 150 volts. It is capable of being discharged at a very rapid rate, viz., 4000 ampères. The battery is installed just about the centre of the network of mains, and is also in direct communication with the principal generating stations. This enables it to be used for a variety of purposes, namely: (1) To assist during the hours of heavy load after being changed from any station which is working on a light load; (2) to act as a regulator all the time—in fact, never being cut off the system; (3) to supply the entire output during hours of light load from one or more stations, thus enabling them to be shut down and operated with two shifts of labour instead of three.

In the Edison station at Lawrence a storage battery of 140 cells of 800 ampère hours capacity is installed on the three-wire system, giving a total capacity of 1600 ampère hours. This battery is chiefly used to carry the peak of the load for two hours daily, and has saved the installation of more generating machinery to meet an increased output, and at the same time has not increased the coal consumption perceptibly. It is also used continuously as a regulator, and to carry the entire load during the greater part of Sunday. At the Germantown Electric Light Station the entire day load is carried by a storage battery, which is charged during the hours of light load after midnight. Before the battery was used the generating plant was run for twenty-four hours continuously, the day load being carried at a loss. After the battery was installed this loss was entirely wiped out and a profit obtained.

Some time ago the Electric Light and Railway Company, at Merrill, installed a plant of 240-type eleven "F" chloride accumulators — capacity 500 ampère hours at 50 ampère rate—in order to increase the lighting capacity and also to regulate the voltage on the railway circuit, as the light and railway dynamos are connected to the same system of shafting and water-wheels, so that every fluctuation in railway demand caused a corresponding fluctuation in the lighting circuit. The battery is connected across the railway circuit in parallel with the railway generator, and charges direct from the generator when current is not required for running the cars, and discharges on the railway circuit when the demand is greater than the generator can supply. So instantaneous is this action, that the power required to operate the generator is practically constant, and thus the light voltage, which, before the battery was installed, varied constantly—sometimes as much as nine volts on each side the three-wire system—is now perfectly steady. This battery has sometimes been called upon to operate the railway for a day at a time, without assistance from the generator. It has capacity for supplying 400 incandescent lamps of 16-candle power for ten hours, or 600 lamps for a shorter

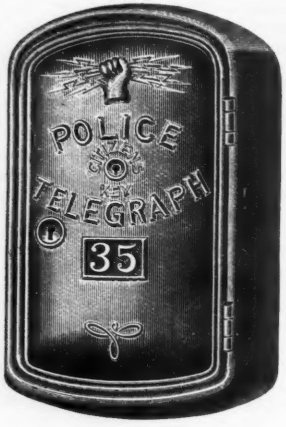
FIG.2



period, and can be utilised for part of the lighting load, thus relieving one of the water-wheels at the power house of lighting duty, so that it can be disconnected from the lighting shaft and solely used for the railway generator. One of the large type "G" batteries, as used in station work, is shown in Fig. 2. It has forty-one plates, 15½in. square, and the cell is 28in. high, the weight with 260 lb. of acid, lead lined tank &c., being 1220 lb. The tank is 21½in. long and 37¾in. wide.

The Electric Storage Battery Company has recently equipped storage battery cars, which are now being operated with success in New York. Instead of placing the batteries under the seats, they are carried on the truck frame, supported on a tray placed between the two axles. With this arrangement the car bodies may be made lighter than was formerly possible. The electrical equipment consists of sixty cells of battery, grouped in two series of thirty cells each, which operate two general electric motors wound for a speed of twenty-four miles an hour. The cells are of the nine-plate traction type. When a car returns for fresh batteries, the discharged cells are removed by means of an electric elevator, carrying a small four-wheeled truck, which rises under the centre of the car. When the cells are on the truck this can be lowered and wheeled off to the charging-room. A new set of batteries is then placed in position by the same machinery.

FIG. 3



A highly interesting exhibit was that of the Gamewell Fire Alarm Telegraph Company, showing the company's system of police and fire alarms. In the fire-alarm system the alarm is given from an iron box attached to a lamp-post, each box being numbered. At the central station a loud gong rings the number of the box, while the number is at the same time displayed by an annunciator over the case containing the gong. Of still greater interest is the company's police telegraph system. An iron box is attached to a building, lamp-post, &c., or placed in a patrol box—resembling a locked sentry box—at convenient points of the city. The exterior of the police box used on lamp-posts, &c., is shown in Figs. 3 and 4, which show the outside and interior of a box used in the patrol box, the door of this police box having no keyhole for the citizen's key, as the door of the patrol box is locked. The interior fittings are alike in both cases. When a policeman goes out on his beat he has orders to report periodically at a certain box, say No. 35. At the required times he reaches the box, unlocks it, pulls the spring lever, shuts the box, and goes off again. His action registers the number of the box and the time of the call on a tape at the central office, and causes the gong to strike three and then five strokes. If the officer at the central station wishes to communicate with the policeman, he can by pressing a button cause a bell to ring in the police box, and when the policeman passes a box or opens it to send in his call, and hears this bell, he takes up the telephone and notifies the office that he is ready to receive a message. Should the policeman have a drunken or dead person to dispose of, he sends in his call, with a special signal calling the officer to the telephone, and notifies him to send a patrol wagon or ambulance. In case of a fight, riot, &c., and help being needed, he turns on an emergency call, which keeps an alarm gong ringing in the central office, a special signal or telephone message being used to indicate what is needed. The central office man has nothing to do but to signal on to the stable for ambulance, reserves, &c., and in a few minutes or seconds the horses of the police wagon will be galloping through the streets to the location of the box from which the signal was given. This system is used in nearly all the large cities, and is of great value.

FIG 4

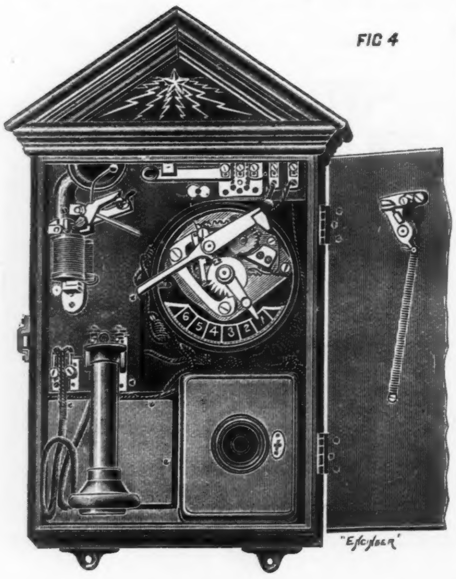


FIG. 5.

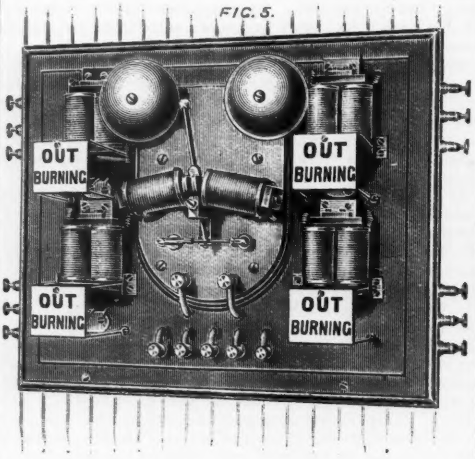
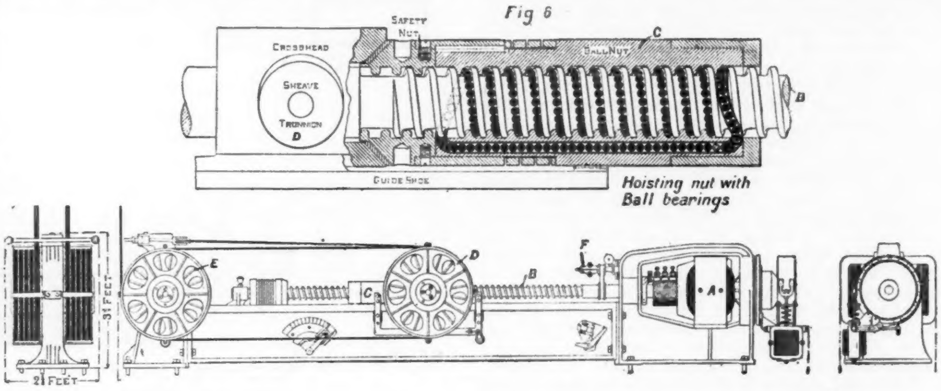


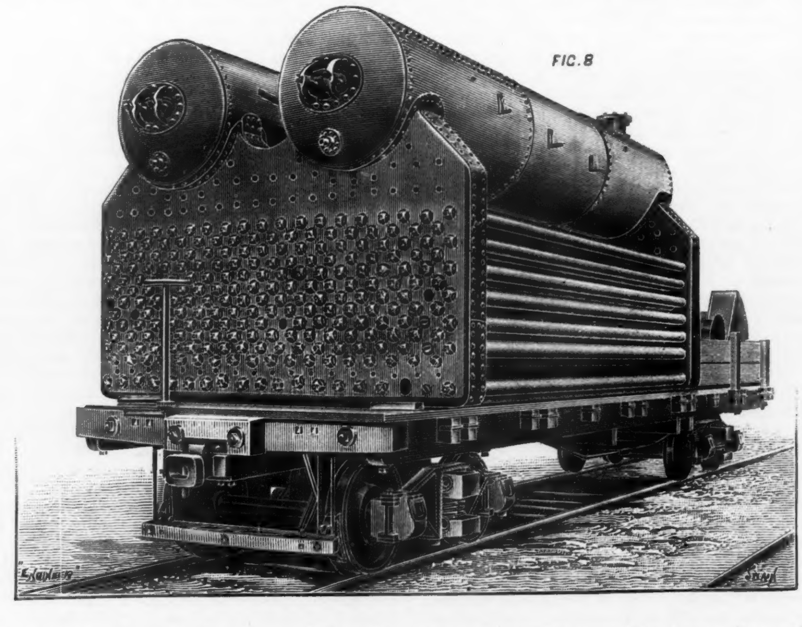
The Russell-See electrical indicator for ships' lights gives visible and audible warnings in case of any light going out. It may also be so fitted that when one lamp goes out another in the same lamp case is at once lighted, while the warning continues to sound until the first or main lamp is relighted. This is shown in Fig. 5, and is applicable to railway signals, &c.

Fig 6



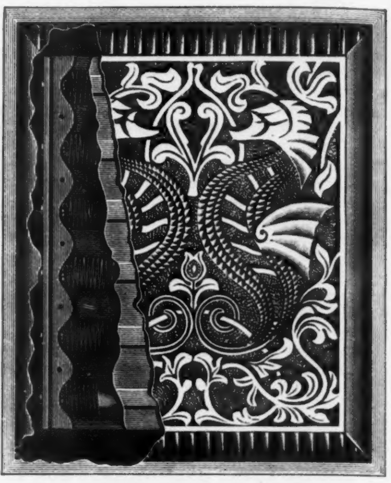
The Sprague electric elevator—Fig. 6—has a motor A, driving the screw B, upon which runs a nut C, carrying the travelling sheave D. The peculiar feature of this is in the use of a ball bearing thread in the nut, the balls returning through the horizontal chamber or passage. The sheave E is journalled in fixed standards on the bed-plate, and F is a speed governor. These are in use in a number of office buildings of five to twenty-one stories in height.

FIC. 8



The Gold Car Heating Company exhibited Gold's electric heater, Fig. 7. The resistance coils are usually 1¼in. diameter, three coils high, the coils being held in position by grooves in the asbestos boards, so that a broken wire could not get out of position and cause a short circuit or burning out of wires or fuses. Three gradations of temperature are obtainable by the use of a special switch. Various forms of ventilating fans are shown. A large exhaust fan is driven by a Lundell motor, from ¼-horse power for an 18in. fan at 1000 revolutions, to 15-horse power for a 6ft. fan at 350 revolutions, the voltage being 115 in all cases, and the ampères from 1·5 to 50. Vertical desk fans and horizontal ceiling fans were shown in great numbers, all operated by individual motors. The desk fan has an alternating current motor, for alternations of 7200 to 16,000, and a voltage of 52 to 104. To the female visitors the exhibit of the American Electric Heating Corporation was a great attraction, as the baking of pastry, the making of coffee, the boiling of water and the ironing of clothes was being carried on by electrically heated ovens, kettles, and laundry irons. Boiling, frying, &c., can be done in the same way, and glue pots, pitch kettles, stoves, portable heaters, &c., can all be heated by electricity.

FIG 7



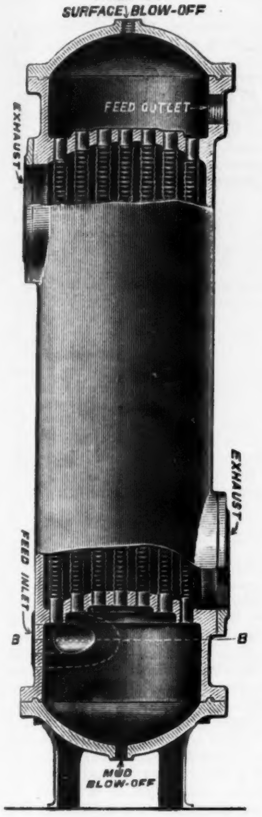
For underground conduits, iron, clay, and wooden pipes and connections were shown. The Interior Conduit and Insulation Company showed its iron and brass armoured conduits, using pipes from 1in. to 3½in. outside diameter, in 10ft. lengths, with screwed sleeve couplings. The Williamsport Wooden Pipe Company showed the Chesnut patent creosoted wooden conduit.

A 40ft. model of the Erie Canal showed the Lamb electric touring system, which has been experimentally installed on a length of four miles.

The power plant consisted of twelve horizontal engines, ten of which were directly connected to the dynamos, while two drove their dynamos by belting. All were horizontal engines, and their smoothness and noiselessness of running were very notable. The "Ideal" engine had its bed mounted on three blocks on the floor to show the freedom from vibration, and another engine had its bed merely resting on the floor, and not secured by any holding-down bolts. Only one of the engines was a compound, but all of them were high-speed engines. Steam was furnished by two Abendroth and Root water-tube boilers of 250-horse power each, carrying 125 lb. steam pressure. The anthracite coal delivered from the street was conveyed by a Hunt noiseless conveyor to a hopper, with spouts leading to the hoppers of the Wilkinson mechanical stokers, which fed it to the inclined grates. The ashes and cinders were carried away by a Hunt ash conveyor. The feed-water was supplied by a Worthington steeple pump, driven by a Crocker-Wheeler electric motor; two Root water-level regulators started the motor automatically when the water fell below the normal level, and stopped the motor as soon as the normal level had again been reached. The Locke automatic damper regulator was used. The first engine—a Phœnix compound—took steam at 125 lb. pressure, but a Foster reducing valve on the steam pipe beyond this engine reduced the pressure to 90 lb. for all the other engines. Two Edison recording gauges were fitted to show the steadiness of pressure maintained on the high-pressure and low-pressure sides of the reducing valve. A Foster automatic stop valve was also placed in the main steam pipe near the boiler, to close instantly in case of a break in the steam pipe or its connections. The exhaust from all the engines passed to a Goubert feed-water heater. The steam pipes were clothed with the Gilmour asbestos covering and the Keasbey magnesia sectional covering.

The arrangement of the engines and dynamos was as follows:—First, a Dick and Clunel — Phœnix — compound non-condensing engine of 125-horse power, with automatic cut-off, directly connected to a Walker generator of 75 kilowatts. Secondly, a Ball and Wood engine of 150-horse power, directly connected to a Siemens and Halske direct current compound wound dynamo of 100 kilowatts and 125 voltage, the speed being 250 revolutions per minute. Thirdly, a "straight-line" engine of 125-horse power, direct connected to a general electric dynamo of 75 kilowatts. Fourthly, a 75-horse power engine driven by compressed air, and directly connected to a Crocker-Wheeler dynamo of 50 kilowatts. Fifthly, an "Ideal" engine, directly connected to an Eddy multipolar generator of 40 kilowatts. Sixthly, a Watertown engine with cylinder 10in. by 12in., directly connected to an Eddy dynamo. Seventhly, a Payne engine of 50-horse power, directly connected to a Card dynamo. Eighthly, a McEwen engine with cylinder 10in. by 10in., directly connected to a Thompson-Ryan dynamo of 40 kilowatts. Ninthly, a single-cylinder Weston engine of 90-horse power, belted to a Warren alternating dynamo of the induction type, 60 kilowatts, having a stationary armature and a field coil. Tenthly, a "safety" engine with cylinder 13in. by 12in., automatic cut-off, 100-horse power, belted to a Crocker-Wheeler dynamo. Eleventhly, a Woodbury engine 9in. by 12in., directly connected to a Fort Wayne direct current generator of 25 kilowatts. Twelfthly, a Shapland vertical engine 6in. by 6in., directly connected to an Eddy generator of 10 kilowatts.

FIG. 9.



In addition to the power plant, as above described, there were several exhibits in connection with power plants for electric stations. All the boilers shown were of the water-tube type, and in addition to the Root boilers in service there were exhibits of the Babcock and Wilcox, the Root, the Westinghouse, the Stirling, the Heine, and the Climax boilers. The two first-named use larger tubes than the others, the tubes being slightly inclined from the horizontal, as are those of the Heine boiler. The Stirling boiler has its rows of tubes nearly vertical, while the Climax boiler has a central vertical shell with interlaced loops of pipe projecting from it, the whole being encased in an outer sectional shell. With this outer shell removed the boiler resembles a pile of coils of wire rope, but in spite of this apparent complication of tubes the boilers are extensively used. Being vertical they occupy a small floor space in proportion to their area. A 500-horse power Heine boiler, mounted on a car for shipment, is shown in Fig. 8. Several forms of mechanical stokers were shown, and numerous steam appliances and fittings, including the Wainwright water-tube feed-water heater shown in Fig. 9. A device which is important enough to call for some attention, and which has been applied in several cases, is the Green's fuel economiser, which may almost be called an auxiliary boiler, always ready for service when emergencies arise, as, for instance, when a cloudy or dark afternoon causes a sudden increase of the demand on the lighting capacity of the electric light plant. It consists essentially of a series of vertical water tubes placed in the main flue between the boilers and the chimney, and absorbing a large amount of the waste heat. It is protected from radiation when the boilers are banked down during a period of small demand for electricity, and furnishes an immediate and ample supply of hot feed-water as soon as the boiler is put in active steaming work. At the power house of the Toronto Electric Railway Company in Canada there are six Scotch or marine boilers, 10ft. diameter and 14ft. long, each having grates 6ft. by 3ft. The Green's economiser consists of 960 tubes in two groups, with a heating surface of about 9600 square feet. A two days' test with and without the economiser showed that in the former case there was a saving of 18·3 per cent. in the quantity of fuel used. As an average the water enters the economiser at 111 deg. Fah., and leaves it at 231 deg., while under ordinary methods the temperature of the feed-water is only about 95 deg. Fig. 10 shows the apparatus as placed in one of the power houses of the Brooklyn City Electric Railway.

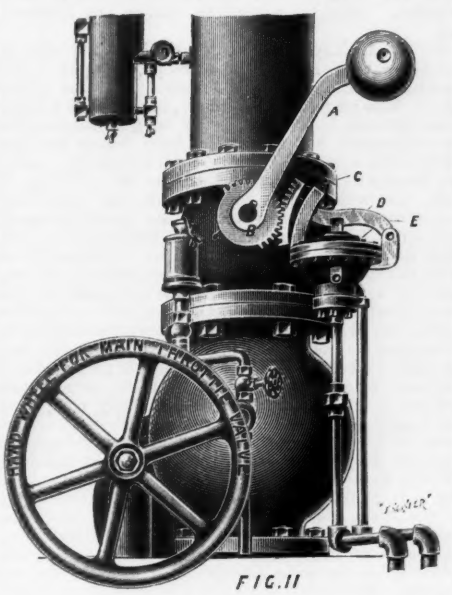


FIG. 11

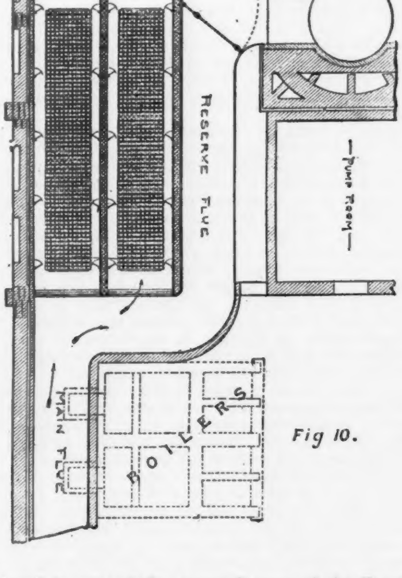

Fig 10.

The Bonta safety engine stop, used in the power house of the North Hudson County Electric Railway, has a system of piping, with sections of glass pipe so placed as to be broken by the governor balls if they rise above the proper level, or to be broken by a broken belt, &c. The pipes are charged with air to a pressure of 40 lb., the pump being automatically started as soon as leakage allows the pressure to fall. The throttle valve on the main steam pipe is a butterfly valve, with a weighted lever A—Fig. 11—and a circular rack B, gearing with the segmental rack C on the lever D. This latter lever is supported on the stem of a piston moved by a rubber diaphragm in the casing E, which is connected with the air pipes. As soon as air is allowed to escape from the pipes, purposely or by the fracture of one of the glass sections, the valve drops and the weighted lever closes the steam valve. Two pipes enter the casing below the diaphragm, one is $\frac{1}{32}$in. diameter, and supplies the air pressure, the other is $\frac{3}{4}$in. diameter, and serves as the exhaust, so that the exhaust being so much larger than the inlet, the air pressure cannot hold up the valve when the exhaust is open.

THE INSTITUTION OF NAVAL ARCHITECTS.

THE summer meeting this year, at Hamburg and Berlin, of the Institution of Naval Architects, promises to be a most memorable event in the annals of the society. When it was made known to the members that a cordial invitation had been issued to them by a select number of prominent officers and others in the Royal Prussian Ministry of State, in the Imperial Ministry of the Interior, of the Marine, of Public Works and of Education, and by representatives of the Chamber of Commerce and the other great industrial institutions of Hamburg, as well as by the city of Berlin, and the various societies of German shipbuilders and civil engineers, no sooner had Mr. Holmes, the indefatigable secretary to the Institute of Naval Architects, completed his capital programme, than applications to attend the meeting poured in so rapidly that it was found essential to limit the number of those to be present to about 450, including lady friends.

The actual muster of members, associates, and their lady friends, who assembled at St. Pancras Station, as a rendezvous, at a quarter to nine upon the evening of June 6th, was about 380; and after the countless Saratoga trunks, containing pretty summer frocks to captivate the hearts of the susceptible Teutons of Berlin and Hamburg, had been stowed away, together with portmanteaus and other gear appertaining to the masculine order, the entire party steamed away to Tilbury in two special trains, to embark upon the magnificent Hamburg American liner, Fürst Bismarck. This fine ocean greyhound, had been most generously and courteously placed at the disposal of the Institution of Naval Architects by the Hamburg American Company, to convey its members direct to Hamburg from the Thames, entirely free of all charge, most sumptuous entertainment being provided for them moreover on the voyage. In all, including the smallest details, the comfort of "the four hundred" was most thoughtfully arranged between the German Company and Mr. Holmes, even labels for luggage "wanted" and "not wanted" on board being forwarded to the intending travellers, who found their light *impedimenta* ready stowed in their cabins almost as soon as they arrived at the vessel.

The voyage across commenced at about four o'clock on Sunday morning, the 7th inst., and the sea, the sky, and the temperature seemed to conspire together to render the passage most delightful. The fine ship sped on her way across the North Sea so easily that even the most indifferent sailors amongst the fair sex seemed to forget that they were crossing the waters, and a delicious breeze carried us right into the mouth of the Elbe at a *very* early hour on Monday morning. So early indeed, that we do not think anyone was awake when we passed Cuxhaven.

Most of our old and well-known friends of previous summer meetings were amongst the party, and a strong contingent of the German members of the Institution, as well as Herr C. Ferd. Lacisz, Chairman of the Hamburg Chamber of Commerce, one of the Reception Committee, also the Naval Attachés of Germany and Austria. Passing up the Elbe to Brunshausen, where we bid farewell to the Fürst Bismarck and her courteous company, to embark in the fast tender Blankenese for conveyance to the city of Hamburg itself, it appeared very clearly, by the emerald look of the pasture fields on the river banks, that the rainless condition which our country has had to deplore during the month of May has not been the fate of our neighbours across the sea. At this point in our voyage, the heartiness of the reception that we were about to experience began to unfold itself. The tender came alongside with an excellent military band, and amidst the strains of the National Anthem, Rule Britannia, and other essentially English tunes, we quickly ran up the river amidst displays of bunting, cheers from the various ships as we passed along, and lastly, a salute of light guns from a signal station at Blankenese-on-the-Elbe, an exquisite spot, where the rounded hills, clothed with trees to the water's edge, stand out upon the right bank of the river, with beautiful villas and more pretentious-looking mansions appearing in the midst of the mass of foliage.

The landing arrangements were excellent, and it was quite a mystery how at least twelve or fourteen hundred packages could be distributed, popped away into conveyances, and rattled off to the various hotels with their owners in something less than twenty minutes. Lord Wolseley with half-a-dozen quartermasters-general could not have done it!

So soon as a light luncheon had been disposed of, our hospitable entertainers carried us off, through the broad and handsome streets of the ancient "Hanse Town," with its network of deep and wide canals penetrating everywhere into the blocks of warehouses and business residences, past elegant churches, two of them with spires rivalling that of Salisbury Cathedral or the dome of St. Paul's in height, which were peeping out from behind the great colonnades here and there — to the Baaken Hafen, which is a huge sheet of water leading out of the Elbe, surrounded with wharves, at which steamers were lying, and having rows of piles driven into the centre line of the Hafen throughout, thus forming an additional wharf, at which countless lines of sailing vessels of large size were moored. Hydraulic cranes were placed at short intervals right around this extensive basin, so that, by means of a continuous gantry upon which they were mounted, they could be made available at any spot where the steamer to be loaded or unloaded happened to be moored.

In order to inspect these basins and the banks of the Elbe itself, which was similarly provided with wharfage appliances, three steamers, handsomely dressed with bunting, and having on board members of the indefatigable Reception Committee, were waiting at the Grassbrook landing-stage, in readiness for our embarkation.

As we steamed up the Baaken Hafen, and then, after being turned round in the narrow waters in the deftest manner by an attendant tug-boat, we emerged upon the bosom of the Elbe, it was impossible to resist a sense of the deepest admiration for the vigour and industry of the Hamburgers, who could thus convert the entire river basin at this spot into one gigantic dock. Here, in the Elbe itself, were double sets of rows of the wharfage piles driven into its bed, and secured to them were steel-built clipper sailing vessels of the very largest size, lines of them one after another, extending for quite a mile. At all those places work was being vigorously carried on, and, although the appearance of the vast mass of shipping gave the idea of a fête day, as every vessel was dressed in bunting in rainbow fashion from stem to stern, this did not prevent the immense activity of the workers all along the lines of wharfage being very observable. In point of fact, one of the members of the Institution present remarked, and with considerable justice, that this was more an object lesson for the working men and artificers in our factories and shipbuilding yards than for naval architects.

Too soon we were swept past the busy scene upon the great waterways, and were landed at the works of Messrs. Blohm and Voss, a short description of which will be found on another page.

The heads of the firm, and many of their obliging employés, were waiting to receive us, and the gallant "four hundred," together with some seventy other members and friends who had not been able to obtain passages in the Fürst Bismarck, but who had meanwhile arrived in Hamburg—a fact omitted to be mentioned—were soon scattered throughout the workshops and building slips of this establishment.

Of the two great steamers upon the slips, the "liner" mentioned in the description presented most points of interest. The system of building differs in many respects from that noticeable in our yards. The various parts of the bracket-framed structure are not only put together, but their several features completed, shaft tunnels and other etceteras, before the framing proceeds. There was a very great difference between the two ships that we saw in course of construction, the frames and scantlings of the larger one being enormously stout and strong, whilst the smaller vessel appeared almost dangerously light in comparison.

The shops and machinery are of the latest and most approved description. The machine and lathe shop is exceptionally fine and lofty, and contains a boring mill for cylinders of very unusual dimensions. In point of fact, it is clear that this firm is prepared to undertake the construction of propelling machinery for the largest steamers either afloat on contemplated.

The boiler-making sheds of Messrs. Blohm and Voss are remarkably spacious, and contain the latest appliances for punching out manholes in one piece and riveting, all by hydraulic power. The shells of the largest sized boilers, weighing from 50 to 100 tons, were suspended from the piston-rod of an hydraulic cylinder attached to tke roof of the building, and power being introduced by a flexible pipe beneath or above the piston, the shell was lowered or raised, as required, with the greatest ease by a single artificer, so as to bring the rivets opposite the hydraulic ram of the riveting machine.

Later on upon Monday evening the members of the Institution were all embarked upon special launches for an extended tour on the Alster Lakes. The scene was most lively and interesting ten thousand electric lights sparkling amongst the trees which surround these beautiful sheets of water, and being reflected across their surfaces, whilst the towering spires of St. Nicholas, St. James, and many other churches, were graceful amongst the masses of buildings and splendid residences, whose gardens descended to the water's edge. In the evening the members and ladies were received by the Senate of the City of Hamburg in the new Rathhaus, a wondrous building replete with taste, though entirely modern. It is in the German renaissance style, and profusely decorated with painting, wood carving, and sculpture. A band dressed in the old mediæval burgher style discoursed excellent music during the evening, a sumptuous supper being also provided.

On Tuesday morning the whole of the 450 members and their lady friends were carried off in countless carriages, a large number of them being private vehicles kindly placed at the disposal of the reception committee, and taken to Luding's Concert House, a fine and well-decorated building, for the reading and discussion of papers.

In the first place, an address of welcome of the warmest and most cordial character was delivered in German by Bürgermeister Dr. Mönckeberg, President of the Senate of Hamburg. It was most ably rendered into English by Mr. George Holmes, and was to the following effect:—Dr. Mönckeberg, on behalf of the town of Hamburg, begged leave to express the satisfaction that all felt at the visit of the Naval Architects' Institute to their city. There always was and always had been the liveliest sympathy between the people of England and those of Hamburg. A community of interests has drawn them together. From mediæval times they had been connected by commercial ties. When circumstances attached to the revolution occasioned by the discovery of America had diverted the shipping interests of England into other interests than those of trade, cargoes were transferred by English merchants to be conveyed in Hamburg ships. Singularly enough, after a lapse of some three hundred years, this day is the anniversary of the first English cargo arriving at Hamburg. Since then British commerce has revived, and Hamburg, after a period of dulness, has been again reawakened to a peaceful competition with its neighbour, to which nothing lends a better aid than naval architecture. They wished the visitors every gratification during their visit, and made heartily welcome.

The Earl of Hopetoun replied in a few pithy and graceful words, acknowledging with warmth the cordiality of the Bürgermeister and people of Hamburg. He expressed his admiration of the vast improvements which had recently been made in the resources of the port of Hamburg, and believed that peaceful rivalry and competition in commerce were the elements of success as regards the countries on both sides of the water. Germans and Britons came from the same stock. The world was large enough for the commerce of both countries. There was no need to tread on one another's toes.

Mr. F. A. Meyer, engineer-in-chief of the city of Hamburg, then read a valuable paper upon "The Maritime Position and the Principal Features of the Port." This we publish elsewhere, but, as it is a paper of the greatest importance, being an able summary of the commercial history of Hamburg during the last thirty years, during which period the tonnage in vessels has increased from one million to six millions of tons, we will briefly touch upon it. Hamburg was always a thriving place as the great Hanseatic Free City, but its importance was threatened in 1881 when it resolved to enter into the Customs Union of the German Empire. At a cost of six millions sterling, however, a large part of which was subscribed by the merchants themselves, a district on both sides of the Elbe marked out on a map with a thick hatched line, supplied to all the guests—was retained in lieu of the old free city, and the splendid docks and basins—marked in grey colour in the map—commenced, together with new store-houses and quays. Now the scheme is practically completed, and a new Hanse town has virtually arisen. In all a space of 2500 acres was separated off, and 10·5 miles of quays for sea-going vessels with railroad tracks and sheds added to the resources of the port. These all remained free. It is the intention of the City of Hamburg to eventually remove the bar between Hamburg and Brunshausen, which prevents large vessels coming further up than the latter place, and to deepen the existing harbour basins so as to accommodate ships with the deepest draught. This is truly a colossal scheme, both as regards what has been carried out and what yet remains to be done.

The discussion on this paper, and the subsequent papers read on Tuesday, will be dealt with next week.

THE ROYAL SOCIETY.

THE ladies' conversazione of the Royal Society took place on Wednesday, 10th June, and in the spacious rooms of Burlington House were shown a large number of interesting exhibits. The Lords of the Committee of Council on Education have arranged for the public exhibition in the western galleries of the Science Museum at South Kensington of a number of the objects, and this exhibition will remain open to the public for about a fortnight. Space will, of course, not permit of a description of all the exhibits, which illustrated very numerous branches of science. We shall, therefore, merely allude to a few of the scientific apparatus which appeared to us of special interest to engineers.

The Cambridge Scientific Instrument Company showed a bifilar pendulum in action. This instrument was designed by Mr. Horace Darwin for observing and recording slow tilts and pulsations of the crust of the earth, by whatever cause they may be produced, and is a modification of that used by the Messrs. Darwin in 1881 at the suggestion of Lord Kelvin. It is possible with this pendulum to observe a tilt of less than $\frac{1}{300}$ of a second, an angle less than that subtended by a line an inch long placed at a distance of a thousand miles, as was shown by the experiments made at Birmingham by Dr. Charles Davison.

A small dynamo for measuring the permeability and hysteresis of iron was shown by Professor M. L. Ayrton, F.R.S., and Mr. T. Mather. This is a piece of apparatus intended for workshop experiments. The specimen to be tested may be in the form of a bar of a bundle of thin plates, and forms the yoke of the field magnet; it is cramped in position, and, through a coil surrounding it, is passed the magnetising current, the winding of the coil being so arranged that the current in ampères is numerically equal either to the magneto-motive force per centimetre of the bar or to one-tenth of that value. When the armature is run at a speed of 1150 revolutions per minute the induction per square centimetre in the bar is approximately equal to 10,000 times the E.M.F. in volts produced. The magnetising current and induction are, therefore, measured by a steady deflection, and not, as is usual, by the instantaneous swing of a ballistic galvanometer. When we examined the apparatus the E.M.F. being used was two volts, and an adjustable carbon resistance was employed. The current was five ampères, but currents up to twenty ampères can be used if desired.

Mr. J. Frith showed the different effects on superimposing a small alternating current on a direct current arc, according as cored carbons or solid carbons are employed. When a small alternating current is superimposed on a direct current arc formed with cored carbons, the oscillations of potential difference and current are in the same direction for all frequencies higher than one and a-half periods per second. On the contrary, if the carbons be solid, the oscillations of potential difference and current are in the opposite direction for all frequencies tried up to 256 periods per second. We were informed that the alternating current was one-fiftieth of the direct current. The lag of phase between the E.M.F and current curves is 180 deg. with solid carbons, while the two curves are in phase with cored carbons.

The Röntgen rays formed the subject of several exhibits. Professor S. P. Thompson, F.R.S., showed the production of electric dust shadows by this means. When the rays are allowed to fall upon an electrified sheet of aluminium placed above a plate of ebonite, they carry electric charges to the plate and electrify it. If objects of metal are laid on the ebonite sheet they intercept the Röntgen rays, and the part of the ebonite surface immediately shaded by them does not become electrified. On removing the ebonite plate and dusting upon it Lichtenberg's powders—mixed sulphur and red lead—the electric shadows become visible. A number of interesting experiments were shown with the apparatus.

Messrs. Siemens Bros. and Co. showed electric discharges in vacuum, a facsimile of Dr. Wm. Watson's vacuum tube of 1751, which was the first apparatus ever constructed for experiments on the electric discharge in a vacuum. The discharge of a Leyden jar passed through 10in., and that from a frictional machine through 3ft., the whole length of the tube. A facsimile of Lord Cavendish's double barometer of 1751; also a facsimile of Dr. Wm. Morgan's shortened barometer of 1785. Dr. Morgan, by long continued boiling of the mercury in a barometer tube, produced a vacuum of such excellence that no discharge would pass, and equal therefore to that in a Hittorf or Crookes' tube of the present day. It is probable that it would have sufficed for the production of Röntgen rays. This apparatus has been designed by Dr. Eugen Obach.

Mr. J. J. H. Teall showed a series of photographs of the electric discharge at various stages during the exhaustion of a Crookes bulb of the Jackson type. Mr. Herbert Jackson gave a demonstration of the use of phosphorescent materials in making *x* rays visible. The tube used to produce the rays is a slight modification—described in the "Proceedings" of the Chemical Society—of a tube originally introduced by Mr. Crookes to illustrate the heating effects of the cathode rays. These are brought to a focus at the centre of curvature of the concave cathode, whence they proceed in nearly a straight line to a platinum plate, from the surface of which they are apparently scattered in all directions. The rays penetrating the glass fall upon phosphorescent bodies and are rendered visible, thus showing the different extents of response of these bodies to such rays.

Mr. F. E. Ives showed a stereoscopic photo-chromoscope. This is an instrument which, with almost equal simplicity, records and reproduces colours more perfectly than the phonograph records and reproduces sounds. The photo-chromoscope camera makes at a single exposure on a commercial photographic sensitive plate three pairs of images, which, by differences in their light and shade, constitute a record of everything tnat excites vision in the two eyes. The stereoscopic photo-chromoscope translates this record to the eyes, so that the object photographed appears to be seen through it.

Professor Roberts-Austen, C.B., F.R.S., showed modifications of an experiment of Monsieur Charles Margot. A wire of aluminium is raised by a current of 30 ampères to a temperature far above the melting point of the metal, but a film of oxide on its surface prevents the wire from breaking. The molten wire through which a current is passing may then be attracted by a magnet.

Sir David L. Salomons, Bart., exhibited a new form of stereoscope; while Mr. T. Andrews, F.R.S., showed a series of accurate micrographs, taken at a high magnifying power, illustrative of the microscopically visible and tangible micro-flaws, almost invariably present in considerable number in steel railway axles, rails, tires, propeller shafts, &c. The presence of these germs of metallic disease in steel—mostly due to sulphur and other impurities—greatly influences the deterioration by fatigue of the metal, and they are a potent factor in inducing the sudden fracture of engineering constructions in steel.

THE BARRY DOCKS.

IN our impression of the 7th of February last we published a map and plan of the Barry Docks and railway connection, and of the site of the East Dock and Lock now under construction, together with some plans and sections of the great lock and photographic view showing the great lock and gates. These extension works are amongst the most remarkable dock works ever constructed, not only because of their size, but because of the unprecedented growth in the trade that has made them necessary. The original Barry Docks, and the first extensions, have been from the first most profitable undertakings, a fact which in itself is very remarkable with regard to works of the kind. Some idea of this may be gathered from the account of the docks which has appeared in the "Proceedings" of the Institution of Civil Engineers. On page 585 we give a few more engravings showing the approach viaduct to the coal tipping towers, which are also shown, and whose positions were shown on the plan, page 136 *ante*, of a steel bridge on the line of the same approach, sections of the pitched slopes and timber wharves of the junction cut between the docks, and of those on the north-western side of the new dock. Type sections of the walls of the same dock on the south-eastern side.

Between the new East Dock and the existing dock, which are connected by the junction cut shown on the plan already referred to and by the plan and three sections on page 585, there is a very large double-faced caisson for maintaining the level inthe new East Dock. This caisson is of the rolling type, and retires into a chamber as indicated. The clear width of opening covered by it is 81ft., which, with the great depth over the sill of 42ft. at the centre, affords accommodation for the largest ships afloat. The caissons and lock gate work generally present numerous features of interest, the gates being opened by direct-acting piston-rods in long cylinders, working on vertical trunnions. The gates and caissons have been made by Messrs. Robert Stephenson and Co., Newcastle-on-Tyne, and the hydraulic machinery by Sir W. G. Armstrong, Mitchell, and Co., of the same place. The contractors for the new dock are Messrs. Price and Wills, who commenced work in August, 1894. Mr. John Wolfe Barry, C.B., Pres. Inst. C.E., is the engineer of the new work, as he has been of the whole of the vast operations which have converted Barry Island in eleven years from an almost unknown land to one of the largest exporting ports in Great Britain, and he is to be congratulated on the success of his designs and on the excellence of the work carried out by the contractors under his superintendence. The works are of such an extensive character that we are at present unable to deal with them further at present.

COMMENTING on the recent explosion on board the French battleship Amiral Duperré, the *Temps* says that it now seems to be established that the explosion was caused by the spontaneous decomposition of the powder in a gun-cartridge under the influence of the heated atmosphere. Our contemporary repeats the statements that the powder magazines are in the Amiral Duperré contiguous to the engine-room, and are entered by a passage through which pass a number of steam pipes. It has often been noticed, adds the *Temps*, that the temperature was more than 104 deg. Fah. in this passage, and at this heat powder undergoes a partial decomposition, giving off inflammable gases. Moreover, it is declared that the recent explosion was the second which has occurred in the Amiral Duperré owing to the same cause. The first accident occurred some years ago and wounded several men. In order to avoid a similar occurrence a refrigerator was bought, but the *Temps* and *Army and Navy Gazette* say that, owing to the irrational manner in which it was fixed, it was of no service.

DEVELOPMENT IN DESIGN AND CONSTRUCTION OF GERMAN MEN-OF-WAR.[*]

By HERR A. DIETRICH, Wirklicher Geheimer Admiralitätsrath, Constructor in Chief of the Imperial German Navy.

THIRTY years ago only one shipyard in Germany was able to construct men-of-war adequate to the demands of the time, the Royal Prussian Dockyard at Danzig. At that time this yard was building the wooden screw frigate Elizabeth, and a short time later two ships for the newly-formed North German Confederation, the Undine, a sailing brig for training purposes, and the armoured screw covette Hanse of 3600 tons displacement; the last one was the first ironclad vessel ever built in Germany. The dockyard at Danzig was fitted out to build only wooden hulls, so the iron unarmoured superstructures of this ship were built up by the Vulcan private dockyard at Stettin, the armour plates were ordered from England. In the year 1869 the first iron armour-clad ever built in Germany, the turret ship Grosser Kurfürst, was commenced in Wilhelmshaven, where the new dockyard was not even nearly finished. The shipyard Vulcan in Stettin started shortly afterwards on the Preussen, a sister vessel of the Grosser Kurfürst. Work on these vessels could only be carried on very slowly during the time of the Franco-German war, so that the first iron armour-clad built in Germany, the Preussen, could not be launched before November, 1873. Her sister ship, the Friedrich der Grosse, was launched in 1874 from the new Imperial Dockyard at Kiel. Owing to the unfinished state of the dockyard at Wilhelmshaven, and the very unfavourable conditions, the Grosser Kurfürst was not ready for launch before September, 1875, six years after work was commenced.

After the Franco-German war the chief of the German Admiralty, General von Stosch, laid out a plan to build up the navy—Flottergründungsplan—according to which work was commenced, but is not quite finished at present, as not all types of ships have the intended number of vessels. To get armour-clads as quickly as possible, it was necessary to place orders abroad, since German shipyards were not efficient enough at that time. The two armoured frigates, Kaiser and Deutschland, were built at Samuda's dockyard from the designs of Sir Edward Reed, and were launched in the year 1874. These two ships form still part of the German battle fleet, after having been reconstructed, as well as it was possible, to suit modern requirements. Since that time no German man-of-war of any considerable size has been built abroad, the German shipyards were in the meantime well fitted to execute all orders. Then those vessels were commenced which suited best the formation of the German coast. According to the building plan, four coast defence armour-clads—Ausfall-Corvettan—of the Sachsen type were ordered, which, on a draught not exceeding 6 m.—19·68ft.—had to carry the heaviest armour of 16in. thickness—Sandwich system—and an armament of six guns of 26 cm. (10in.) calibre. These ships are nearly the first armour-clads ever constructed on the citadel type. The keel of the Sachsen was laid as early as 1874, and she was launched in 1877; the first citadel ships, the Inflexible and the Duilio, were launched in 1876. The last of the three sister ships of the Sachsen type, the Baden, was not launched till 1880.

Coast defence had to be considered before everything else, and, therefore, contemporaneously with the above-mentioned vessels, work was commenced, not on monitors as at first planned, but on ironclad gunboats of the Wespe type. These boats, of 1000 tons displacement, were plated 8in. (200 mm.) armour, carried one gun of 12in. (30·5 cm.) calibre, and drew only 3 m. (9·84ft.) Eleven of these boats were built. For a long time no armour-clad was built in Germany except the Oldenburg, which was started in March, 1883, and finished in November, 1886. She was intended to be the fifth vessel of the Sachsen type; but, owing to want of money, she had to be made smaller and of quite another type. With the armour-clad Siegfried a quite new type was started in 1887, also intended for coast defence only, and especially for the mouth of the river Elbe, on account of the construction of the Kaiser Wilhelm Canal. Eight vessels of this type were built, but the two last, the Aegir and Odin, are somewhat different from the sister ships, being constructed after the citadel type ships. The main condition for these vessels also is the low draught, only 5·5 m. (18ft.) They carry, on a displacement of 3500 tons, heavy ordnance, three 24 cm. guns, arranged especially for defending river estuaries, and are armoured with 240 mm. ($9\frac{7}{16}$in.) plates, and have a speed of 15 knots. Thus, since 1873, three different types of armour-clads, of 7400 tons, 3500 tons, and 1000 tons, were built for coast defence, each type designed and executed for this limited purpose.

The construction of seagoing armour-clad battleships, which have to advance farther out, in order to defend the coasts more effectually, was not commenced before 1889, after a lapse of sixteen years. Then, however, four vessels of the same design were started simultaneously; these are the Brandenburg, Weissenburg, Wörth, and Kurfürst Friedrich Wilhelm, of more than 10,000 tons displacement, a speed of 17 knots, 400 mm. (15·75in.) thickness of armour in the belt which surrounds the water-line, and, in addition to a reduced light armament, six guns of 28 cm. (11in.) calibre in three revolving turrets. Two still bigger ships, the Ersatz-Preussen and Ersatz-Friedrich der Grosse—to replace the before-mentioned ships—whose principal dimensions were materially affected and restricted by the small size of the existing German dry docks, are being built now at the Imperial Dockyard at Wilhelmshaven. The development of the unarmoured ships was strongly influenced by closely adhering to and imitating the types of screw frigates and corvettes existing in the year 1871 in the German Navy, the type of the full-rigged single screw frigates and corvettes with broadside guns without any armour protection. The vessels had full sailing capacity, and great stress was laid on the training of the crew in the rigging, but the fighting capacity of the vessels was neglected. Such vessels were constructed even as late as 1887—Charlotte, Arcona, Alexandrine.

Cruisers to suit modern requirements were not commenced before 1885. Three of those vessels of the second-class have been built up to now, the Irene, Princess Wilhelm, and the Kaiserin Augusta; the last of which is the first triple-screw ship which crossed the Atlantic. Up to 1895 only one moderately armed and protected cruiser of the third-class—Gefion—was built, together with a number of smaller cruisers of the fourth-class—Bussard type. By this time the want of cruisers was felt so severely that three second-class cruisers of more than 5600 tons—Ersatz-Freya, K and L—and one first-class armoured cruiser of 10,650 tons—Ersatz-Leipzig—were commenced. To these vessels were added this year two more cruisers of the second-class—M and N.

A special feature in the German Navy has always been the "avisos," speedy vessels of small fighting capacity, designed only to serve as scouts for the fleet. But soon these vessels were required to fight, especially after the introduction of the torpedo; in consequence, the vital parts had to be protected. Out of the last German vessel of any size built abroad, by the Thames Ironworks, 1875-76, viz., the Zieten, the modern German "avisos" were developed. These were first of all the Blitz and Pfeil, with under-water torpedo armament and of 16 knots speed, forerunners of the later-built English boats, Surprise and Alacrity. The Greif, of 19 knots speed, succeeded in 1885, and was followed by the Wacht and Jagd, of 19½ knots speed, and fitted with a protective deck. After these come two small "avisos" of the same speed, the Meteor and Comet, of 1000 tons, and then the "aviso" Hohenzollern, a splendid vessel fitted out as an Imperial yacht, with 21·5 knots speed, of about 4000 tons displacement. The last of the "avisos" is the Hela, of 2000 tons displacement, now beginning her trials. I will pass over the torpedo division boats and torpedo-boats, even though the development of these craft in Germany is very interesting.

This short review, perhaps, shows some of the difficulties which had to be dealt with to build up the Navy. But now the strong influence of his Majesty the Emperor, supported by the great efficiency of the German shipyards and steel works, and all those other trades which help to finish a modern man-of-war, opened up the way for the new development. In the years after 1870, as the material was needed for the naval vessels to be built in Germany, ironworks had first to prepare to fulfil the orders for material of the same quality as was required by the English rules, which were adhered to. Plates and angles were soon produced, just of the same good quality as in England; but it was difficult to forge heavy pieces, like stems, sternposts, and rudder frames for bigger ships, and for several years these had to be ordered from England. To-day in this respect, too, German works are equal to any

---

[*] Read at the summer meeting of the thirty-seventh session of the Institution of Naval Architects, June 9th.

demand; the stem and sternpost, with rudder frame of one of the armour-clads of the Brandenburg type made by Krupp was much admired at the Exhibition in Chicago. The production of armour plates for our armour-clad ships and vessels shows a rather slow development. The armour plates were first ordered in England from Charles Cammell and Co. and John Brown and Co., both in Sheffield. In 1876 the Dillinger Works on the Saar made preparations to produce iron armour, and furnished first the 203 mm. (8in.) plates for a number of armoured gunboats of the Wespe class, afterwards plates of 254 mm. and 305 mm. (10in. and 12in.) thick for two ships of the Sachsen type—the Baden and Würtemberg; and in 1879-80 plates 305 mm. (12in.) thick for the reconstruction of the König Wilhelm.

In 1880 the Dillinger works obtained the English "Wilson" patent for producing steel-faced armour plates—compound armour—and furnished those plates, first for the Oldenburg, and thereafter for all armour-plated German ships, until in 1890 steel-faced plates were superseded by nickel armour-plates, which are also produced by the Dillinger works. Since 1891 the works of Krupp, in Essen, also have made great preparations to manufacture armour plates. These two factories now work together, and not only can turn out all the armour-plates needed in Germany, but execute foreign orders also. The latest face-hardened armour-plates of these two works are perhaps the best plates produced anywhere. Germany has become perfectly independent in this respect also.

England has been Germany's teacher in the construction of hulls, engines, and boilers. Those ships which were bought from and built in England for the German Navy had to serve as standards from which to imitate the details. Our inspectors kept their eyes and ears open, and the many publications, as, for instance, Sir Edward Reed's and Sir William White's precious works, the "Transactions" of the Institution of Naval Architects, the instructive articles in the periodicals, THE ENGINEER and *Engineering*, offered an abundance of information to those who intended to learn, like the Germans of that time. The engines of the screw frigate Elizabeth had to be ordered, in 1867, from England—Maudslay—because they could not be designed and built in Germany. The first larger screw engines for navy ships were constructed in 1871, and in the following years at the works of Egells, in Berlin, for the corvettes Ariadne and Luise, and at the Vulcan works in Stettin, 1874, for the armour-clad Hansa. These engines were of English model in general design, and entirely so in all details. But since that time German industry has made such progress in the building of large marine engines that it now comes up to the highest standard, and has grown to be wholly independent. Already, nearly twenty years ago, German manufacturers went their own way in working out the plans and the details of engines and boilers, taking advantage of all the new inventions in England and France. To-day, the construction of navy vessels in Germany is worked out from original ideas, in order to fulfil the military requirements for each type. The new German men-of-war now in course of construction will, in many respects, be worthy of interest, since all modern improvements in science and technical knowledge has been taken advantage of to produce a most perfect tool for any war purpose.

I shall describe now, in a few words, some arrangements in which German men-of-war, in my opinion, differ from the English-built warships. I mention here, first of all, the divisions into water-tight compartments. The armour-clads, armoured cruisers, and protected cruisers are divided into as many water-tight compartments as it was deemed possible without interfering with the working of the vessel. Perhaps this is carried out already too far, and the service on board may be obstructed. The paper of Lord Charles Beresford read before the meeting of the Institution in March of this year mentions those considerations which prompted the constructor here to carry every athwartship-bulkhead above the waterline, without any door in it. Any door may be left open, therefore one has to accept the probability that it will be left open; and, consequently, it is better to have no door at all. Communication from one engine-room to the other, from one stokehold to the other, must be established only over the protective deck, above water, or may be carried on below by telegraphs and speaking tubes. Only in the athwartship bulkheads which are beneath the protective under-water deck of citadel ships, or in the foremost and aftermost parts of protected cruisers, doors are permitted. This circumstance speaks strongly against the construction of such vessels. The above-mentioned principle is strictly adhered to in all new German Navy vessels. It is difficult to ventilate a ship divided in this way. Air from above must directly lead into, and out of, each compartment between two athwartship bulkheads, which has direct access from above. Only for the forward and aft compartments underneath the protective under-water decks air ducts are carried through the athwartship bulkheads, and water-tight shutters have to be provided for, which are perhaps insufficient, but have to be made use of in vessels of the citadel type.

Modern vessels suffer a great deal from the heat which radiates from the steam piping belonging to the large number of auxiliary engines installed in all parts of the ship, and which supplies the ship with continuous steam heating. All attempts of engineers to cover these pipes with non-conducting materials, and to insulate them so as to prevent this radiating heat, have entirely failed, and every room through which a steam pipe is carried is heated very disagreeably. The best method of counteracting these effects of steam engines and steam pipes was found to be by omitting them, and by employing electricity, the conducting wire taking the place of the steam pipe. Only by driving the many fans made necessary for the water-tight compartments by electricity is the division into so many compartments rendered at all possible. All new German warships in course of construction have electricity as motive power, not only for those ventilating fans, but also for the turning gear of the 15 mc. gun-turrets, for ammunition hoists, for boat-hoisting, and coaling winches, and such like gear. For the turning gear and ammunition lifts of the heavy guns, hydraulic power has been retained, and steam is still used for the steering gear where it was especially difficult to install the electric motor, as well as for the anchor windlasses, which are only comparatively seldom used. Only one vessel in the German Navy, the nearly finished Aegir, is experimentally fitted throughout with electric appliances even for steering gear and windlasses. The results of these experimental installations will decide if, in the future, electricity can be used more extensively for motive power on board ships, and if the heat sources can be further dispensed with.

His Majesty's cruiser Kaiserin Augusta, of 6300 tons displacement, over 13,000 indicated horse-power, and with a speed at load draught of over 21½ knots, is the first German vessel with three screw propellers; she is also the first triple-screw steamer which ever crossed the Atlantic. [In 1893, in order to be present at the celebration of the four hundred years' jubilee of the discovery of America.] It is hardly necessary to discuss at any length the considerations which caused the adoption of a system accepted already some time before in Italy for the Tripoli, and decided on in France for the Dupuy de Lôme. By dividing the excessive motive power of the modern warships into three parts, the smaller engines could be more easily constructed, and, as they do not stand so high, it is less difficult to place the vertical engines underneath the protective deck. In a combat additional security of working is provided, as compared with the twin-screw ships, and, lastly, saving of fuel should result in using only one of the smaller engines when cruising at reduced speed. Although the engine-room staff has to be augmented, greater engine space is required, and the three engines themselves are to a small extent heavier, these disadvantages were not considered important enough to outweigh the advantages of the triple screw for all battleships, and for the first and second-class cruisers in the German Navy. Triple screws are provided for the new battleships Ersatz-Preussen and Ersatz-Friedrich der Grosse, the armoured cruiser Ersatz-Leipzig, and the second-class cruisers Ersatz-Freya, K, L, M, and N.

In all the new ships the armament and its protection, in accordance with the latest experience, requires so much of the weight which makes up the displacement, that somewhere else weight had to be saved, which would be available for armour and guns. Nowhere could weight be reduced, since more was asked for everywhere. Though, to facilitate work, more auxiliary machinery is installed, the number of the crew is not diminished; these engines require even more attendants. The weight of hull is, through rational construction and reduction of the scantlings, lessened as much as the strains will permit, in some cases even in excess of a sufficient margin of safety. Considerable reduction in the weight of the ships' hulls was effected by the restricted use of wood. The splinters of wood scattered by penetrating shells were always dreaded, the experiences drawn from the battle at Yalu have clearly shown how dangerous such combustible material as wood is for the construction of a ship and its fittings.

In the outfit and the construction of the new German ships wood is used only for a few minor parts. Wooden deck planks are no longer laid, steel deck plating is covered with linoleum, sometimes over a layer of cork. In the crews' quarters the sides of the ships are not ceiled; in the officers' rooms the ceiling is made of steel plates, 1½ mm. thick, and lined with cork. For cabin bulkheads the steel is covered with thin woollen cloth, and with cork lining underneath where it is desirable to exclude sound or lower the temperature. Where heat is radiated from engine or funnel casings cork lining is resorted to. All wood is removed from the ammunition rooms, save the racks for shells and powder charges, which are still made of wood. For all ladders and steps steel is used. The handrails on the conning bridges are no longer of wood, but of some other material which will not burn or splinter, and which is more agreeable to the touch of the hand than steel or brass. Chart-houses and captains' rooms on bridges are entirely made of steel, and fitted out with non-combustible materials. Since all such changes will be a little exaggerated, it seemed to be advisable to abandon wood for the interior fittings, and especially for the furniture, and to resort to fireproof material, which will not splinter. Many things were tried: furniture was made of steel and aluminium, lined with cork and covered with linoleum or canvas, but it was not equal to wood furniture. Only the bedsteads are constructed of iron, steel, or brass, which materials are also much in use ashore. The insignificant quantity of wood in the few pieces of furniture when ignited is not the dangerous source of smoke, but much more is the outfit of the state-rooms, the mattresses, blankets, clothing, books, &c. Therefore, for the present, wood cannot be abandoned entirely. Top and signal masts, flag poles, &c., will be made of steel, but there one cannot save weight.

The fighting capacity of the ships is without doubt increased through these innovations, since the ship is less apt to burn, the effects of splinters are restricted, and considerable weight is saved, which is available for ordnance and armour. But still greater reductions were needed, and though the power of the engines had to be raised their weight had to be kept as low as possible. In the engine department the condenser plant is now exceedingly complicated; also, the boilers are at present very heavy in consequence of the high pressure used; boiler feed-water, which was formerly not needed, has to be carried; and the weight of machinery has increased above that of the old engines with low pressure when the boilers were fed with sea water. Granted the modern engines consume less coal, might it not be better to save weight with a less complicated engine and carry more coal? I only refer here to engines of war vessels where quite other conditions prevail than in the mercantile marine, where the vessels always go at full power, while the man-of-war very seldom utilises the full power of her engines and boilers. This is a chapter by itself worth the investigation of a specialist, who could thoroughly clear up this question, but it is outside the scope of this paper.

The engine weights could not be reduced, so one had to look for reduction to the boilers, which represent such a considerable weight. Here a reduction could be had by adopting the water-tube boiler. This problem of the water-tube boilers is one of the most important and difficult ones in modern marine engineering, and is very actively discussed in the English, French, and German navies. Subsequently to the French and English navies, the German has also taken decided steps, accepting water-tube boilers for many vessels. Not less than four different kinds of water-tube boilers are adopted for the new German ships now in course of construction, viz.:—Aegir, armour-clad fourth-class, 4800 indicated horse-power, Thornycroft boilers; Ersatz-Freya, cruiser, second-class, 9000 indicated horse-power, Niclausse boilers; K, cruiser, second-class, 9000 indicated horse-power, Belleville boilers; L, cruiser, second-class, 9000 indicated horse-power, Dürr boilers. The two armour-clads of the first-class, as well as the armoured cruiser, Ersatz-Leipzig, will be fitted with two cylindrical boilers and one-third water-tube boilers of the system, which will be found best from the results of the trial trips soon to be commenced. The English Navy seems to prefer Belleville boilers for bigger ships, the French Navy provides for these ships, together with the Belleville boiler, those of D'Allest and of Niclausse; the Dürr boilers are very similar to those last mentioned. The trial trips of this and the next two years will show more clearly the value of the different types of the boilers. All the so-called theoretical discussions and contentions are useless; only practical experience can decide this question, but years may lapse before it is settled. In the future the use of water-tube boilers cannot be avoided in navies. By fitting them for one-third of the engine power—13,000 indicated horse-power—in first-class ironclads about 140 tons of weight are saved; and the reduction of weight for second-class cruisers of 9000 indicated horse-power where water-tube boilers are entirely used amounts to about 280 tons. The combined working of water-tube and cylindrical boilers was the subject of a paper at the meetings of the Institution last year, but no decided opinion was arrived at. In the Dutch Navy, too, the combined system is adopted for the three new large cruisers, but in a different form to ours, as the Dutch intend to generate two-thirds of the engine power with water-tube boilers, and one-third with cylindrical boilers. The leading idea in the German arrangement is that, as a rule, the vessel steams at reduced speed, and uses only one set of cylindrical boilers, keeping the other free for easy cleaning. The water-tube boilers are provided in order to get up, in the shortest time, steam for the highest engine power; at all other times fires are drawn from those boilers.

The greater coal consumption seems to be a drawback to the use of water-tube boilers; only actual trials of ships in service will decide the merits of each type of boiler. In the meantime we are in the dark. It is at any rate hazardous to proceed with the use of water-tube boilers, so long as we have only the experience acquired in the French Navy, and nowhere else; but the increased fighting power demanded, which cannot be provided otherwise, forces us to such action. What an engineer of note wrote a short time ago in the *Daily News* is certainly correct, viz., "In the next war the side which has the best boilers will win."

Some more characteristic features of German ships of war could be brought forward; for instance, the fact that the protective underwater deck is never cut through for ventilation or coaling purposes; then the peculiar construction of the cork-filled coffer-dams; the singular shape of the stern and rudder; the very high bow and low stern; but it would take too much time to thoroughly deal with them. The annexed table and three sheets of sketches contain the particulars of the German men-of-war of the latest type. I trust, though this paper is necessarily very incomplete on account of the very short time available for its preparation, the Institution will perceive from it how hard we had to work here in Germany to call into existence a navy in the short space of a quarter of a century; how we had to study and to test, in order to achieve the result that the vessels planned by German designers, and constructed out of German material in German dockyards, shall be fully equal to the vessels of the old English and French navies. I hope that this may be the case.

THE Belgian Conseil Supérieure de l'Industrie et Commerce, which was organised in accordance with a Royal Decree in 1890, has been reconstituted by another Royal Decree of 15th January last; and the elections to this arbitration board have just taken place. The members for the Province of Liège, returned without opposition, include for engine construction, M. Charles Beer, engineer, and M. Timmermans, general manager of the Atelier de la Meuse; for the iron industry, M. Greiner, general manager of the Cockerill Works, and M. A. Race, Administrateur Délégué of the Pugrée Company; for metalliferous mines, M. Taskin, director of the Angleur Company, M. C. Timmerhaus, engineer to the Vielle-Montagne Company; for collieries, M. Léon d'Andrimont, President of the Hasard Colliery, M. Joseph Dubois, general manager of the Marrihaye Colliery, and one of the inventors of the Dubois-François rock drill and *bosseyeuse*, and M. C. Petit, general manager of the Bois d'Avroy Colliery. The great questions now to be dealt with by this body are the labour contract, and compensation for injuries sustained during work.

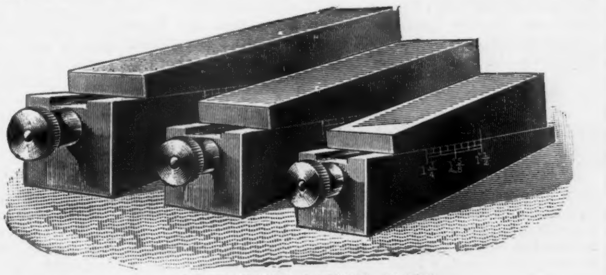
THE VULCAN WORKS, STETTIN.

In our last impression, on page 564, we gave a bird's-eye view of these celebrated works and a general description. We now give above and on page 588 a series of reduced photographic pictures, which will serve to convey an idea of the magnitude and importance of the place. Fig. 1 possesses special interest, as it shows the ways prepared for laying the keel of what will be the largest ship in the world—a great liner of 20,000 tons displacement and 28,000 indicated horse-power. Figs. 2, 3, and 4 explain themselves. In the engravings above, Fig. 5 is a view taken in one of the large turning shops, Fig. 6 is an erecting shop in which locomotives are in progress of construction, Fig. 7 is another view in the same shop, Fig. 8 is a view in the heavy erecting shop for marine work, Fig. 9 shows a marine engine in course of erection, and Fig. 10 is a view taken in the main erecting shop, of which Fig. 3 is an external view.

THE SUNDALE PACKING BLOCK.

The accompanying illustrations will explain themselves to engineers, and the want of a packing block capable of being quickly and accurately adjusted in thickness, and so arranged as not to shake loose in working, has long been felt, and the packing block illustrated herewith has been introduced by Messrs. Selig, Sonnenthal, and Co. to fill such want, and so supersede the large and miscellaneous assortment of old nuts, old washers, broken flanges, bits of tin, &c. &c., which are to be found in nearly all engineers' shops, piled up by the side of every machine, for use as packing blocks in setting jobs. The Sundale blocks are quickly adjusted, and are provided with a fine adjustment by screw, which is continuous throughout the whole range. The adjusting screw also admits of the use of a steeper angle of wedge than is possible in the case of ordinary plain double wedges without a screw. This gives a wider range, and there is no danger of shaking back. The packing block can be accurately adjusted to any definite thickness—within its capacity—by means of a scale on the side.



THE SUNDALE PACKING BLOCK

THE LIGHTING CORPORATION, LIMITED.

Like many others, we watched with some touch of sentimental misgiving the demolition of the chapel at Bloomsbury, and wondered what sort of corporation had ventured to appropriate this site for purposes of commerce; therefore, in answer to an invitation, we attended various functions arranged and provided by the Lighting Corporation, Limited. The functions consisted of a banquet in the basement of the Woolpack Restaurant, Gracechurch-street, E.C., a subsequent dramatic entertainment at the Duke of York's Theatre, and a final reception and supper in some windowless rooms at the Corporation's offices in Bloomsbury. From the speeches after the banquet we gathered that these agreeable functions had been arranged so as to enable the visitors to judge as to the efficiency of the illumination and ventilation, effected by the improved Wenham light, which the Lighting Corporation is now exploiting, and had installed in various places, along Piccadilly for instance, as well as in the room in which we were, in the theatre in which we would be, and in the suite of rooms to be visited still later. The basement of the Woolpack is a large low-pitched room, and was remarkably stuffy when we arrived; but later on, when the lights were turned up, the atmosphere cleared and the ventilation improved, although about 200 people were present, many of them smoking, and the lamps, like the old Wenham lamps when new, gave a bright and pleasant light. At the theatre, too, the ventilation was good, whilst at the crowded reception afterwards we were much struck by the excellence of the light, for the rooms were artistically decorated with ornament in various materials, stone, metal, wood, fabrics, and paper, and in diverse colours, besides oil paintings, water colours, and sculpture—all could be seen to good effect by the single light in the centre of each room; and further, in spite of the crowded assembly in these windowless rooms, no oppressive sensation and yet no draught could be noticed.

We, therefore, the following day visited the works privately in order to see for ourselves the appliances adopted to produce the gratifying effects that had been so generally admired the evening before; and we are now able to give a description of these appliances. They consist of arrangements—(1) For governing, conveying, pre-heating, and consuming the gas; (2) for admitting, pre-heating, and directing the course of the air supply; and (3) for disposing of the products of combustion and hot air, which, of course, constitutes the ventilative factor. All these things have been done before, and all have been done in a somewhat similar manner, and many failures have been recorded; but with the various improvements introduced in the present instance, success is anticipated by the enterprising Corporation.

The governor is a bell governor with a mercury lute, the pressure being regulated by a lever with sliding weight resting on the top of the bell, and is very steady under great variations of consumption; a main pipe with a spiral bye-pass takes the gas to the ring burner, to which part of the air is supplied at the centre through radiating channels meeting in a central chamber, and at the other end opening into the air; the balance of the air supply enters through perforation in the periphery of a ring, between which and a lower ring the flange of a suspended hemispherical glass is loosely clamped, silicated cotton packing being used to avoid the contact of the glass and metallic surfaces; the glass globe directs the air on to the flame. The hot products of combustion and heated waste gases escape through an annular space round the ring burner, pass between and heat the radiating air supply channels previously mentioned, are then directed by a conical sheet metal screen to a cylindrical sheet metal chimney which surrounds the gas supply pipes, and these, of course, become heated. The waste gases are then delivered into a gas-box, from which they pass into a flue, suitably placed in floors and walls, and protected by non-conducting silicated cotton; into the same flue the hot air in the vicinity of the lamp is drawn through orifices in the outer casing. The flue terminates in the external air with a cowl having an upright cone in the mouth to prevent any back draught. A pilot flame is used for lighting the lamp.

THE INCORPORATED GAS INSTITUTE.

THE thirty-third annual general meeting of this Institute opened on Tuesday, the 9th inst., at the rooms of the Society of Arts, London, under the presidency of Mr. W. R. Chester, M. Inst. C.E. The report of the Council shows a net increase in the membership of 44 during the year. The loss sustained by the death of Mr. Denny Lane, of Cork, a former president, meets with special notice. The accounts show a net profit of £86 11s. 1d., making up a balance of £935 14s. 6d., to be carried to next year's profit-and-loss account. The president's medal and a prize of £10 have been awarded to Mr. D. Irving, of Bristol, for a paper on "Unaccounted-for Gas," read at last year's meeting; a second prize of £6 to Mr. Lewis T. Wright, of Westminster, for one on "Matters of Interest in Connection with the Washing of Crude Coal Gas"; and a third prize of £4 to Mr. C. S. Ellery, of Bath, for a paper entitled "Some Improvements in Methods of Manufacturing Sulphate of Ammonia."

The President, in his inaugural address, alluded to the flourishing condition of the Institute, which he said had recovered from the effects of the secessions which culminated eight years ago in the formation of a rival body. He then reviewed the growth of the gas industry in the country during the past year. According to the Board of Trade returns, about 1¾ millions sterling represents the increase in the capital invested in gas undertakings, and the make of gas shows an increase of over 3 per cent. He then referred to the erstwhile hated rival, but now "colleague" of gas, viz., electricity, and proceeding from general remarks to the particular case of the gas and electricity supplies of Nottingham, he concluded that a given amount of light cost for electricity 2·72 times as much as for gas. It was pleasing to hear the engineer of the Corporation Gasworks bearing testimony to the fact that since the electricity works at Nottingham opened two years ago, there had not been a single failure, nor a single instance of the full voltage not having been maintained. We notice that the President credited the ordinary flat-flame burner with an efficiency of 3½ candles per cubic foot of Nottingham gas. The Metropolitan consumer, who seldom invests in the "London Argand" burner, and hence regards so high a duty for gas as fabulous, will envy his Nottingham brethren their richer supply. Mr. Chester proceeded to disclaim, on behalf of the gas industry, a desire for abnormally cheap coal, and considered that fluctuations in price were more injurious to it than a somewhat high but stable cost of its raw material. He blamed the oft-reviled middleman for the prevailing low price of sulphate of ammonia, and recommended the Sulphate Manufacturer's Association to the attention of members. But so long as Beckton has unused retort house stages on which to store several months' production of sulphate, the middleman can scarcely be considered to hold producers "in the hollow of his hand." Tar and its products advanced in price, notwithstanding the alleged attempt on the part of distillers to keep it low. The President suggested the establishment of a sliding scale, based on the profits of the distiller, to fix the price of tar, and disapproved of the erection of competing tar distilleries in gas works. He considered there were no signs of the coke market rallying, but recommended members to endeavour to improve the quality of their product, and to sort and cut it according to the needs of customers; and instanced the wide market which Nottingham coke thus obtains, in support of his advice. The gaseous firing of retorts had, in his opinion, effected a saving of at least 2¼d. per 1000 cubic feet of gas made, and the principle had the advantage of being readily applied to inclined retort settings. He considered this system "especially well adapted to moderate-sized works, where full employment cannot be found for carbonising machinery." The introduction of the latter he regarded as a blessing to both employer and employed; but he spoke with some hesitation of the advantages of an auxiliary carburetted water-gas plant. We must confess to a sense of disappointment that he did not make more than a passing allusion to improvements in the methods of purification, and to the recovery of cyanogen compounds from gas, more especially as there were no papers before this year's meeting dealing with these matters. The process for the extraction of cyanogen, which has been used in London for more than a year, is no secret; but many others have been recently tried on an extensive scale, and the criticism of so good a chemist as Mr. Chester would have been very welcome. On the subject of gasholder construction he was less reticent, and spoke of rope-guided holders from actual experience of their working. He discussed at some length the transfer of gas undertakings from private to public control, and the more rapid fall in the interest charges in the case of local authority supply than in the case of company supply. He concluded his address with an appeal to members to come to the aid of the Benevolent Fund of the Institute, which has of late years inadequately met the growing demands upon it.

The President's address, though singularly free from contentious matter, was highly suggestive, and showed an excellent appreciation of the present position of the gas industry. We have already said that we wish he would have seen his way to have amplified it in more than one direction, especially as some of the papers which followed it were of comparatively little merit, and might with the discussions they induced have been curtailed with much advantage. The paper by Mr. E. Lloyd Pease, of Stockton, on "New Details in Gasholder Construction," was, however, of considerable interest. The "new details" referred solely to rope-guided holders, four typical cases of gasholder construction or enlargement on this plan were taken as the basis of the paper. Of these, the most notable was that of the three-lift holder recently constructed at Middlesbrough. This has a diameter of 184ft., and consists of three lifts 30ft. deep, in a steel tank on the surface of the ground. This is the largest columnless gasholder in existence, and as it was said to have worked in a perfectly satisfactory manner, Mr. Pease may be considered to have vindicated the efficiency of rope guiding for large as well as small holders. He pointed out that the weight of the Middlesbrough holder, 350 tons, was employed in the construction of one column half as high as it is wide, carried and formed into a rigid whole by the confined gas, while the weight of the standards which would be employed if ropes were not used would be 200 tons distributed in eighteen posts tied together by light girders and diagonal bracing, supporting its own weight, and, in comparison, decidedly loose jointed. He thought the suggestion that this light iron tracery was there to give assistance to the holder by preventing distortion was almost absurd.

"Gas Engines as Economical Motors" was the title of a paper by Mr. J. Holliday, of Scarborough, which was also read on Tuesday. The information given was taken from various sources, and in some cases was of rather dubious worth. The author anticipated the supplanting of steam by gas power in all small and moderate-sized electric lighting stations. He decided against the introduction of differential rates of supply for gas according to the purpose for which it was consumed, and believed that the use of motors would quickly spread on a general cheapening of gas supply. He suggested that gas works should supply motors on hire to suitably accredited consumers.

The proceedings on Wednesday, the 10th inst., opened with a lecture by Prof. Frank Clowes, D.Sc., of Nottingham, on "Explosive Mixtures of Combustible Gases with Air." The lecture was admirably illustrated by diagrams and experiments, and though most of the information has been given on other occasions, it formed a very welcome item in the Institute's programme. The following were among the more interesting points of the lecture:—The limiting percentages of coal-gas forming explosive mixtures with air are 5 and 28; of water-gas, 9 and 55. Many mixtures of gas and air which would not fire from above could be fired from below. The risk of a mixture being fired explosively increases with different gases in the following order:—Methane, ethylene, coal-gas, water-gas, carbon monoxide, hydrogen. Carbonic oxide, whether derived from the incomplete combustion of gas, or from escapes of water-gas, or similar mixtures, is a highly dangerous addition to the air; 0·2 per cent. produces an ill effect, and 2·0 per cent. is fatal to human beings if breathed for a short time. Dr. J. S. Haldane some years ago systematised the tests for carbonic oxide depending on the colour change it produces in blood. The detection of inflammable gas in air and its approximate estimation are best carried out by the flame-cap test, which has been brought to perfection by Dr. Clowes. He introduces a small hydrogen flame of definite height into the mixture to be tested, and observes the height of the halo or flame-cap which is produced. As a matter of common prudence, the flame is, of course, within a safety-lamp, and is fed from a small steel cylinder of the compressed gas. The hydrogen flame is superior to other flames on account of its greater heat, which produces a more vigorous combustion of the combustible gas in the air, or, in other words, a larger flame-cap. Since the heat of the flame determines the size of the flame-cap, it is evident that variations in its size will prevent accurate estimations. For the general use of Professor Clowes' hydrogen flame inflammable gas detector, tables have been prepared giving the percentages of coal gas in the air corresponding to different heights of the flame-cap. The instrument has now a fairly extended use in collieries and in gas-works, and is made in a conveniently portable form by Messrs. W. J. Fraser and Co., of London. A specimen of the Redwood-Clowes inflammable vapour detector was also exhibited to the meeting.

After the passing of a vote of thanks to Professor Clowes, a paper by Mr. E. H. Stevenson, M. Inst. C.E., on "The Principles Governing the Transfer of Gas Undertakings," was read and discussed. Briefly, the author gave in outline a method of capitalising the maintainable profit, and from the sum so found he proposed to make deductions on account of any part of the works or plant which was not in a proper state of efficiency. The discussion drifted into side issues, and scarcely touched the actual subject of the paper.

On Wednesday afternoon a paper by Mr. Norton H. Humphrys, A.M.I.C.E., of Salisbury, on "Letting Gas Apparatus on Hire," was discussed, in conjunction with one by Mr. A. Dougall, of Tunbridge Wells, on "The Popularisation of Gas," The latter dealt solely with the coin-meter system, which was accepted by the meeting without one dissentient voice as a valuable aid to the spread of the use of gas, and remunerative to gas companies. The improvements in coin meters have won over many gas managers who were formerly opposed to their introduction. The discussion on these papers frequently showed a lamentable want of appreciation of the relative importance of details, and much valuable time was wasted on trivialities.

The proceedings on Thursday, the 11th inst., the last day of the meeting, will be reported next week. The members of the Institute, of whom some 250 have attended the meetings, were asked to join a steamboat trip down the Thames on Friday, the 12th inst.

THE SHIPYARD AND FLOATING DOCKS OF MESSRS. BLOHM AND VOSS, HAMBURG-STEINWARDER.

THIS shipyard is to be visited by the Institution of Naval Architects on June 8th, and is situated on the Elbe, and at the entrance of the Schanzengraben, and has an area of over twenty-five acres. Founded originally on a modest basis, it is now, after having been in course of time considerably extended, in a position to build the largest vessels both for the Government and the merchant navy. The ground necessary has been recovered by dredging 654,000 cubic yards of sand from out the Elbe, so that the depth of water in front of the shipyard now permits the largest vessels to lie directly alongside the quay. The quays have a frontage of 1804ft. on the Elbe and of 787ft. on the Schanzengraben.

Directly opposite the shipyard are situated the two floating docks constructed of iron and consisting of six sections, each dock capable of lifting ships of a length of more than 300ft. A third much larger dock, capable of lifting vessels up to 17,500 tons displacement is now in course of construction. The large new buildings are entirely constructed of iron and brick. At the entrance of the shipyard are the main offices, consisting of the private rooms of the principals, where all the plans for the construction of the ships are originated, the offices for the shipbuilding and marine engineering departments, the general offices and a large model room, in which all the models of vessels built by the firm are exhibited.

At the east of the dockyard is the shipbuilding establishment, of an area of 5500 square metres, containing the furnaces, bending blocks, rolling, bevelling, punching, shearing and planing machines, as well as hydraulic riveting machines. In front of these works are the seven berths for the construction of ships up to 558ft. and more long. Next to these berths are the sheds of the angle-smiths, locksmiths, coppersmiths, and tinners. Opposite to the entrance of the yard are the engine works, fitted with the latest and most modern machinery for the construction of engines up to the largest sizes. Here we find large planing and cylinder boring machines, lathes, cranes, &c.; moreover three engines of 150-horse power each for driving the different lines of shaftings, as well as the dynamos for the six electric travelling cranes, capable of lifting from ten to thirty tons each.

The boiler works are also fitted with a full complement of special machinery and hydraulic tools for bending and flanging plates for boilers up to the largest sizes and highest pressures. Here are also a number of swing cranes, as well as three travelling cranes of a capacity of thirty tons each, driven partly hydraulically, partly by electricity. The smithy is of large size, and contains sixty hearths, &c., as well as different steam hammers of various sizes. The joinery works are a large building three stories high, entirely built of iron and brick and fitted with special machinery, such as moulding, planing, dovetailing, boring and milling machines, band and circular saws. Next to the joinery works is the sawmill, with large rack and band saws and planing machines, and adjoining this the carpenter's shop.

On the quays are the necessary cranes for lifting the material and placing on board the engines and boilers. There is a large shear-leg crane of a capacity of 100 tons, and a height of 92ft.; two stationary cranes of 20 tons each, one derrick crane of 10 tons, and three travelling cranes. A second very large derrick crane of 150 tons capacity at a radius of 66ft., 45 tons at 105ft. radius, and a height of 147ft. above ground, is in course of construction. Three tank locomotives and more than a hundred trucks are employed in transporting material, and a complete telephone system connects all departments. The number of workmen employed averages more than three thousand.

HORSELESS CARRIAGE NOTES.

THE following account by the Hon. Evelyn Ellis of a recent tour in his Daimler motor carriage will prove generally interesting:—"In February last I took my Daimler motor carriage to Marseilles with the object of touring through the Alpes Maritimes and the country generally lying between Marseilles and the Italian frontier. I found no road, however steep, which had a hard foundation, that could not be ascended, but, of course, at reduced speeds. The actual horse-power of my carriage is 3½; the weight of the carriage and motor complete 16 cwt. With three passengers, but without luggage, the vehicle attained an average speed of about eleven miles per hour on fairly level roads, with fine weather. I returned to Marseilles, and left that city for Havre during the third week in May, the route taken being *viâ* Lyons, Dijon, Paris, and Rouen, the distance, as nearly as possible, being 660 miles. The whole of the way to Dijon—300 miles—a very heavy northerly gale, 'the mistral,' accompanied with rain, hail and dust, blew right in our teeth, and throughout the journey to Havre, with the exception of two days, rain and strong northerly winds prevailed. The routine of each day was as follows:—Starting at 8 a.m., our first stoppage would be at 12.30 for lunch; the journey being resumed at 2 p.m., and a halt for the night made about 6 p.m., the distance generally travelled being from seventy to eighty miles each day. The speed during the whole of the journey averaged nine miles per hour, and the amount of petrol used as fuel was under twenty-nine gallons, with one gallon of lubricating oil and grease, the total representing, at English prices, a cost of 28s. 6d. The running time of the whole journey was nine days. During my stay on the Riviera I wore out a new set of solid rubber tires, owing to many of the roads being in such a bad state of repair, and for the trip from Marseilles to Havre I had to replace them with old wheels which were used in England last year. I also wore out two band brakes, owing to the many long and steep descents. Besides the foregoing, which was simply fair wear and tear, my only expense during the whole period from my first arrival on the Riviera until I reached Havre was 2f., this being incurred for a broken hook. I have frequently been told that a great objection to these carriages is the necessity of having a skilled engineer in charge, but this idea is utterly wrong. During the above journey I was accompanied by a man who had been fifteen years a coachman, but whose employer had given up his horses. This man being known to one of the firm who built my carriage, spent six weeks at their works learning the general details of the machinery, and how to drive the vehicle, and though he has never had any other mechanical training he has been everything I could require. Now, if this is possible in France, surely the average English coachman has enough intelligence to do the same, and would find no difficulty in adapting himself to the new order of things when this method of locomotion becomes more common."

MUCH doubt exists in the minds of many who are making oil and spirit motors as to the restrictions under which the light oils may legally be used. The subject is one which can be stated as far as the Acts are concerned, and on some points not defined by the Acts we can only be guided by a few decisions. To put the matter on a more definite footing, however, the Government is now, by Mr. Mundella's Committee, taking evidence, and inquiring generally as to the results of the various uses of petroleum, and as to the necessary regulations, more particularly on points such as the storage, use, public and private, sale, and carriage of light oils. Freedom to use these oils appears at present to be neutralised by limits as to storage.

RAILWAY MATTERS.

The total length of electric tramways in operation in Europe at the beginning of the present year was 902 kiloms. = 560 miles, stocked with 1747 cars, against 700 kiloms. = 435 miles and 1236 cars at the beginning of 1895. Of the above length Great Britain only possesses 109 kiloms. = 67 miles, while Germany has 406 kiloms. = 252 miles, and France 132 kiloms. = 82 miles. The trolley system is adopted on nine lines, as compared with three with underground conductor and eight with accumulators.

Comparative figures of the coal consumed per car mile run on French tramways, employing different methods of propulsion, are contained in an article on electric lines by E. Cadiat in the *Portefeuille Economique des Machines*. As regards storage-battery traction, on the lines from St. Denis to the Madeleine, and from the Opera to Neuilly, the car mileage aggregated, in 1893, 502,060, or 1376 car miles per day. The steam engines at St. Denis furnished for this service a total of 6500 H.P. hours, or 4·72 H.P. hours per car mile.

The Government of Chili, it is reported, will propose to limit the expenses of the State railways to the amount of their earnings, and will submit a Bill which will not permit the companies in future to fall back upon the National Exchequer for larger assistance. According to this Bill the directors of the railway department will yearly fix the estimates for the coming twelve months, and the total expenditure will have to be paid out of the income and not be provided for, as has been the case in the past, in the Budget, in which railways will no longer figure.

A new fast train service between New York and Buffalo, over the Lehigh Valley Railroad, was started May 17th. The trains will make the run of 448·6 miles in ten hours, leaving each end of the line at noon. On the first trip the northbound train made the run in nine hours forty-six minutes, or nine hours eight minutes running time. Each train, *Engineering News* says, consists of a combination baggage, dining, and smoking car, 77ft. long, with library, writing desks, &c., two Pullman day cars, and an observation parlour car, with a woman's sitting room and seating capacity for twenty-eighty persons.

A general classification of the accidents in April in America shows:—

	Collisions.	Derailments.	Other accid's.	Total.	Per cent.
Defects of road	0	14	0	14	15
Defects of equipment	4	13	0	17	18
Negligence in operating	12	7	0	19	20
Unforeseen obstructions	0	11	1	12	13
Unexplained	5	27	0	32	34
Total	21	72	1	94	100

When the Light Railways Bill was under consideration of the House on Thursday, the 4th inst., amendments were agreed to, (1) that the advance made for the construction of any light railway should not exceed one-half the cost of construction; (2) that the period during which the rateable value of the land used by the railway should not be increased shall be ten years instead of fifteen; (3) that the holding of a local inquiry shall be required in all cases; (4) a clause requiring the Board of Trade to report to Parliament when circumstances wherein variations in the provisions of the Lands Clauses Acts are necessary; and (5) Clause 13 was amended to allow in certain cases 10 per cent. for compulsory sale of land. It may be hoped that "cost of construction" will be properly defined.

On Tuesday a trial was made with one of the new engines which are being built for the fast service of the East Coast passenger traffic, the run being from Newcastle to Tweedmouth and back with six of the improved carriages attached. The engine "1869" has 20in. cylinders, with 27in. stroke, and 7ft. 7¼in. coupled driving wheels. The length of the coupling rods is 9ft. 6in., or 6in. longer than the coupling rods of any existing express engine. The driving wheels have 6in. greater diameter for coupled wheels than any other engine running. The engine works at a boiler pressure of of 175 lb. per square inch, but can be worked up to 200 lb. The tender will carry five tons of coal, but only 3000 gallons of water, against 4500 gallons with the engines now in use for this traffic. The North-Eastern is to introduce the pick-up arrangement similar to that in use on the London and North-Western, and the pick-up troughs which will be between Lucker and Beal will be ready by July. Fifteen engines of this type are to be constructed. The running of both engine and carriages was considered satisfactory.

Writing on electric tramways for London, a correspondent in Kingston, N.Y., U.S.A., writes to the *Times* saying:—"I notice that negotiations are in progress to acquire the street car lines from the County Council, and to adopt the system of electric traction. I wish to strike a note of warning which I firmly believe every Englishman who has visited America will re-echo. In every city or town of importance in the States they have these electric street car lines, and, although they are not so bad in small towns, in the big cities they are a positive danger and menace to life and property. In Brooklyn alone there have been 148 lives lost up to the present time through accidents with these cars. Over here the almighty dollar rules the roost, and life and safety are a secondary matter; but, thank God, in England the protection of life and property is the first duty of every loyal subject. Therefore I hope every effort will be made to keep these death-dealing vehicles out of the metropolis. Regarding the statement that the underground conduit system was running successfully in New York, I would say that this is false. The only underground system is that of the cable cars, all electric cars being run on the overhead trolley system, which necessitates the running of a bare, overhead, live wire through the streets at a height of about 18ft. above the ground, and carrying a current of immense power, to come into contact with which means instant death. I hope the time will never come when money will be able to buy up an Englishman's rights to protect his life and property."

That is how the matter strikes an English visitor. The following is what a writer in *Cassier's Magazine* says:—"New York's underground trolley electric street railroad has thoroughly demonstrated its practicability by running satisfactorily throughout a winter season which has been particularly troublesome to street car traffic by reason of a number of heavy snowstorms. For several years the much spoken-of Budapest road and the Blackpool line in England stood alone as successful practical examples of this type of construction, while failures of competing designs seemed to be the order of the day, chiefly because it was the inventor who was at work, making paper designs and taking out patents, and not the engineer. To the latter the problem of building a street railroad which would take its power from an electric conductor in an underground conduit ought long ago have been one of comparatively easy solution, had he but taken it in hand, and the strange part of it might seem to be that he did not sooner devote himself to it. One explanation may be found in the lack of inducement which probably existed to the construction of such a road. Overhead trolley lines were cheaper to build and consequently more alluring to capital, and in some places, where these were prohibited by local legislation, the cable system had already been installed, and was giving fair service. With the more and more certain promise, however, of greater economy of operation which electric car propulsion held in view, and with the ultimate design of extending the electric system to its cable sections, the Metropolitan Traction Company of New York decided last year to take up the subject in a practical way, and the result has been, as stated, thoroughly successful. A little simplicity and common sense are of vastly more importance in a work of this kind than any amount of complex refinement, and this is very well demonstrated in the plant in question."

NOTES AND MEMORANDA.

Insurance companies have decided that electric lighting, when the wiring is well done—and they have formulated special rules on the subject—is the safest of all illuminants. Statistics show the following comparative risks:—Fires in one year from paraffin and kerosene, 259; from gas, 110; matches used for gas, 35; candles, 88; arc electric lights, seven; and incandescent electric lights, only one.

The total area of land surface of the earth is calculated to be 28·3 per cent., and that of sea as 71·7 of the earth's surface, certain assumptions being made for the unknown polar regions. The ratio of land to water surface is thus 1 : 2·54, by Professor Hermann Wagner. Other interesting levels are that of the mean height of the land 700 metres—2300ft.—above actual sea level; and of the condensation spheroid, *i.e.*, the physical globe if the water were condensed to the density of the rocks of the crust, 1300 metres—or 4260ft.—below present sea level.

A paper on "The Application of the Formula of Clapyron to the Melting Point of Benzine," has been printed in the *Comptes Rendus* by M. R. Demerliac. It records an experimental study of the lowering of the melting point of benzene by pressure. The pressure gauge used had been calibrated against a mercury column directly, and the alterations in temperature were measured to ·001 deg. by the changes in resistance of an iron wire forming an arm of a Wheatstone's bridge. The alteration in melting point for an additional pressure of one atmosphere calculated from Clapyron's formula is 0·02936 deg.; the experimental figure is ·0294, the difference being less than the errors of observation.

At a recent meeting of the Berlin Meteorological Society, Dr. Schwalbe spoke on the investigation of some important theories of atmospheric electricity, and added an account of experiments he had made on the dissipation of electricity by vapour. A metal plate insulated, charged to ten volts, and connected with a Thomson's quadrant electrometer, discharged itself in exactly the same time when dry as when wetted with water or other easily vaporised fluid. Sprinkling with finely pulverised quartz greatly hastened the discharge; coarsely powdered glass to a less extent. The time of discharge was the same for a rough as for a polished plate. He considered that these experiments had settled the fact that vapour does not discharge an electrified body, but that fine powders do.

Circumstances connected with the drying of timber, that happened and were also noticed by accident, have been communicated to *Cosmos*. Some oak posts were placed for convenience against the wall of a shed, with the root end upwards; and when they were removed, a viscous substance was noticed on the ground where they had stood, while it was also remarked that the timber was drier than might have been expected from the time that had elapsed since it was cut. As the rapid drying of the posts could only be attributed to the inverted position, which had permitted the sap to run off, the same method was henceforth adopted for all timber, while rods were placed under the lower ends, for permitting the sap to run off more freely, and the same favourable results were observed.

Messrs. Morehead and De Chalmot state categorically in the *Journal* of the American Chemical Society that the Willson Aluminium Company can make calcium carbide at less than £5 per ton, including wear and tear and interest on capital. Mr. Hunt (*loc. cit.*) "believes, from his own experience in the matter, that it can be manufactured by suitably devised apparatus at a rate of £8 10s. per ton." In Dr. Ahren's recent book "Die Metallcarbide, &c.," the selling price at Neuhausen is quoted at £20 per ton, the material being about 79 per cent. pure. Morehead and De Chalmot record a large number of experiments made on the large scale, the average purity of their product being 80 per cent. Using unslaked lime, and a current of 1800 ampères at 80 volts, they obtained from their carbide on an average 4·97 cubic feet of acetylene per lb., or 48·33 cubic feet per horse-power day—twenty-four hours. With air slaked lime the yield fell to 39·52 cubic feet.

In giving an abstract of a report on "The Caking Power of Coals," by L. Campredon, the *Journal* of the Society of Chemical Industry says: "To determine the caking power of a coal, the sample is ground sufficiently fine to pass through a sieve of 400 holes per square centimetre. It is then diluted with varying proportions of fine dry sand and the mixture ignited in a covered crucible, the character of the resulting coke being noted. The weight of the coal being taken as unity, the largest amount of sand that the sample will bear and yet give a coherent coke represents the caking power of the coal. In the case of some Welsh coals, the coke takes the form of a powder without the addition of any diluent; therefore the number found on examining different samples may vary from 0 to 17. It should be noted that mere exposure to the atmosphere affects this property of coal; at elevated temperatures the loss of caking power is still more rapid. There does not, however, seem to be any connection between the quantity of volatile matter in the sample and its caking power."

On the glass of a Crookes tube, which has been used for some time, being heated in the blow pipe, it assumes a dead or dull appearance which, observed M. Gouy to the Paris Academy of Science, at first leads to the supposition that it has become devitrified. The alteration is, however, limited to the internal surface of the tube, being so much more marked as the glass has received a more intense cathodic radiation, and being absent in the portions not so exposed. The microscope shows that this dull surface is chiefly constituted by a vast number of gaseous bubbles in the substance of the glass, but near its surface. On the heating being continued these bubbles unite and increase in volume, so that at length they become visible through the magnifying glass, and sometimes even to the naked eye. Glass, therefore, which has been exposed to intense cathodic rays gives out numerous gas bubbles when softened by heat, a phenomenon which occurs in no other case; and it would seem that the cathodic rays cause the gases of the tube to penetrate into the substance of the glass, afterwards remaining occluded until set free by the softening of the glass. The experiments which gave rise to these observations were made with four glass tubes slightly differing one from another, but only one of them showed a considerable number of bubbles in the portions most exposed to the cathodic rays.

At a recent meeting of the Société Francaise de Physique, M. Broca showed the new Bandsept burners for perfect combustion, applicable to heating as well as lighting by gas, which they render more economical. When, observed M. Broca, gas, previously mixed with air, is consumed in Bunsen burners, the mixture of the gas and air is very imperfect, and if the air has been admitted in exact proportion for combustion, the latter will be complete at some points, leaving an excess of oxygen, and incomplete at others, the combustible gas being in excess, whence arises the want of homogeneity of the Bunsen flame, which shows a cold and blue internal zone. These conditions are evidently very defective for a proper utilisation of the gas, which does not give out all the heat of which it is capable. In the Bandsept burner, on the contrary, the veins or minute currents of air and gas are forced to mingle intimately by means of a series of imbricated and truncated conical caps; and, to cause the molecules of the two gases to assume a whirling motion, they are made to pass through two metal gauzes, the wires of one opposite the holes of the other, placed at the combustion orifice. The effect of this arrangement is, not to increase the maximum temperature of a burner, but to render the flame much hotter for producing incandescence in the caps, which may be made much thicker, higher, and stronger than usual, while attaining the same degree of incandescence.

MISCELLANEA.

The East London Harbour Board, South Africa, have ordered a powerful twin-screw sand pump hopper dredger of 1000 tons capacity from Messrs. William Simons and Co., Renfrew. This vessel will be fitted with special arrangements for dredging the bar at East London.

Her Majesty's Secretary of State for Foreign Affairs has received from her Majesty's Consulate at Palermo a despatch reporting that tenders have been invited by the municipality of Messina for a concession to be given for the supply of drinking water for the city and suburbs of Messina. Particulars may be seen on application to the Commercial Department of the Foreign-office, between the hours of 11 and 6.

Rotherham has suffered from scarcity of water, requiring the supply to be turned off from 9.30 p.m. to 5.30 a.m. The Sheffield Corporation have been approached with a view to obtain a temporary service, and arrangements are now being made between the Waterworks Committee of Rotherham and the Sheffield Waterworks Department for that purpose. The Sheffield and Rotherham Corporations have their two systems so near to each other that the connection can be made in a week at the merely nominal cost of some £300. The members of the Rotherham Corporation have expressed themselves very warmly upon "the generous and neighbourly way in which Sheffield has met them."

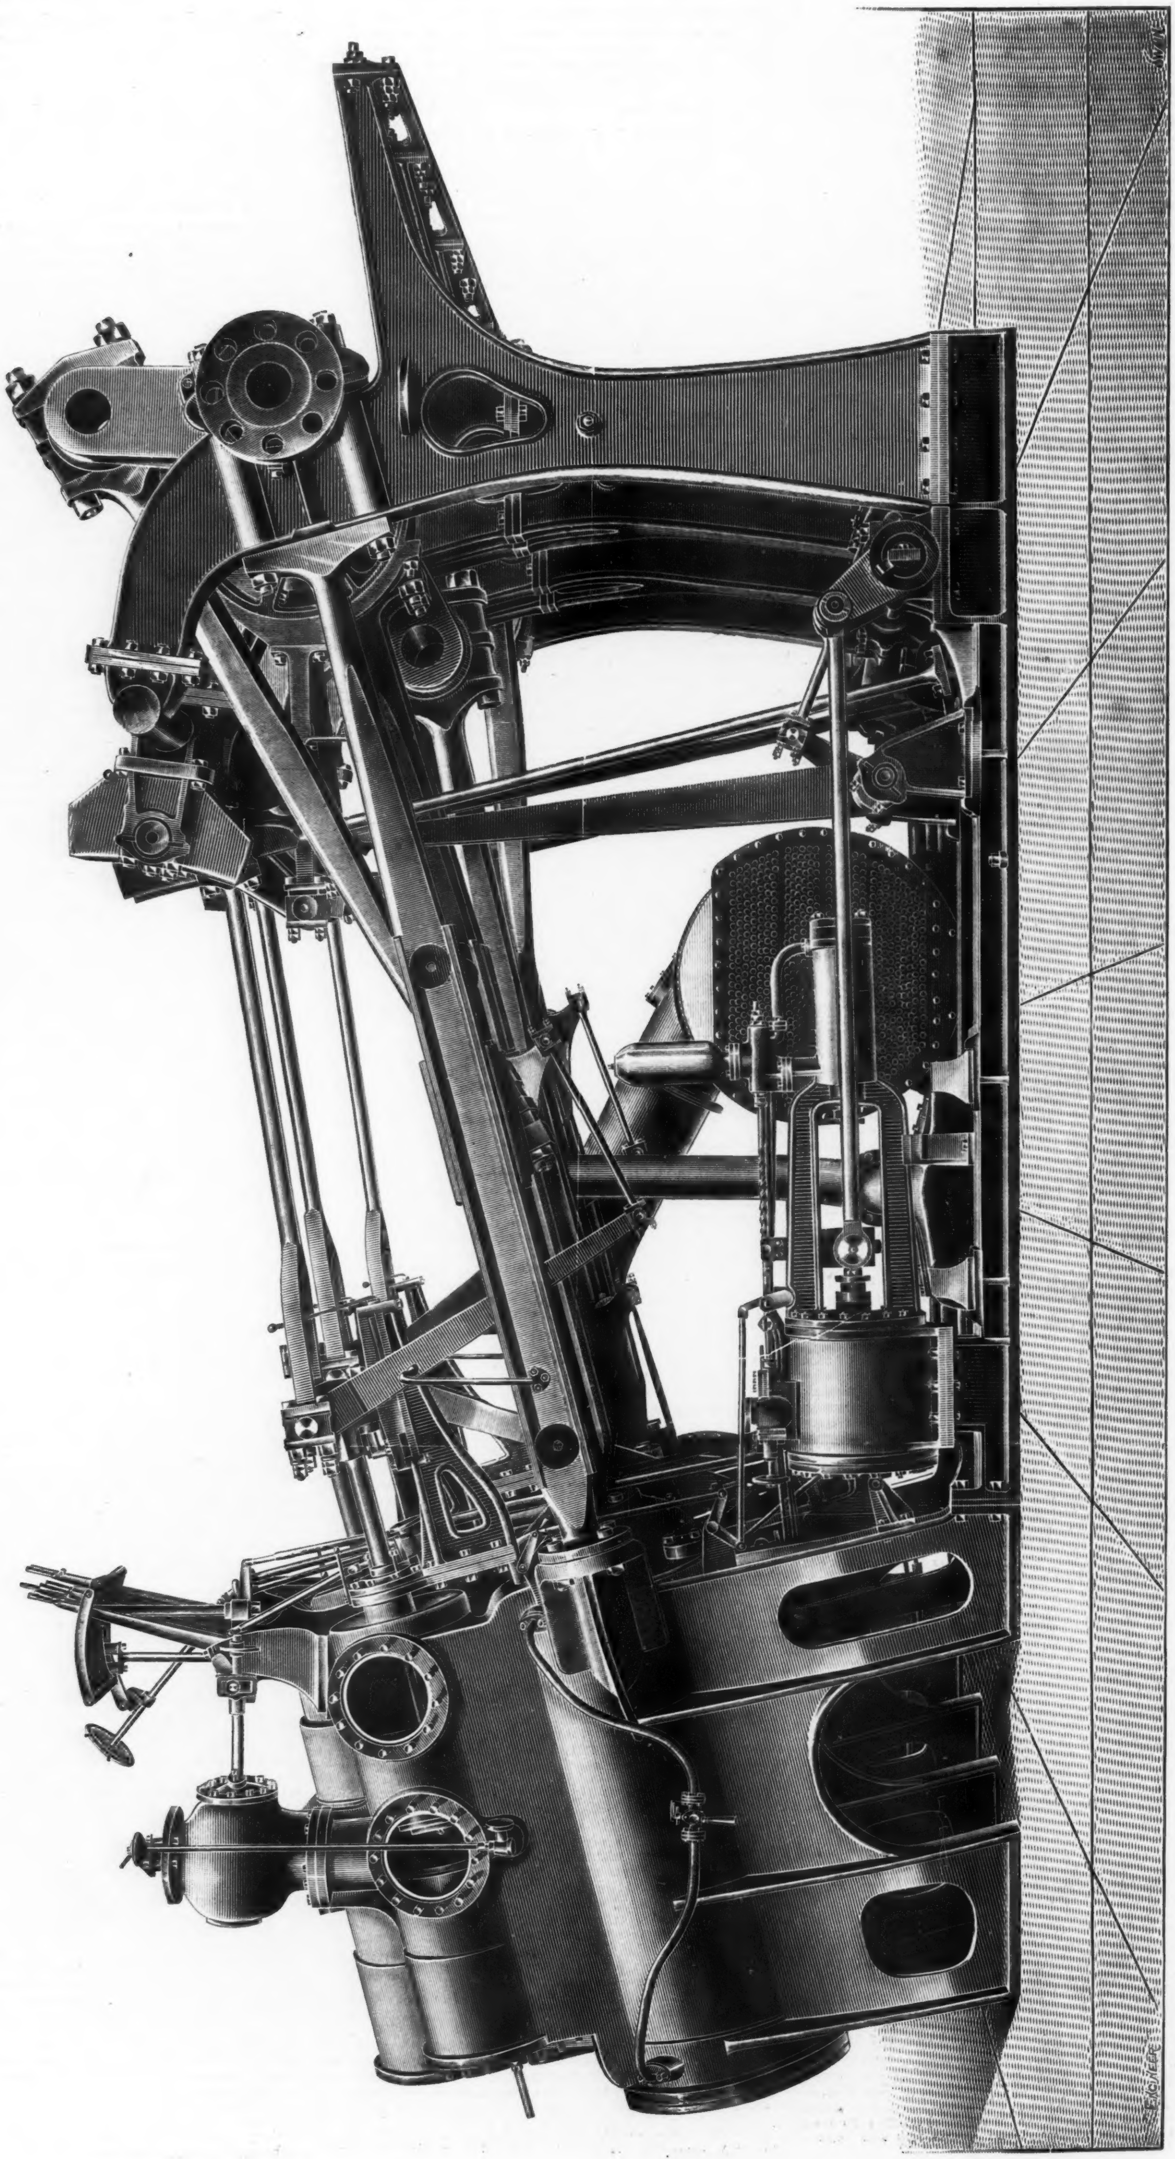
The Sheffield Art Crafts Guild opened its second exhibition on Monday in Cutlers' Hall. Nearly every art craft existing in Sheffield is represented, the collection of works including examples of the fine productions of craftsmen of the past as well as of modern days. One of the most interesting features is the display of old Sheffield plate. The exhibits of decorative and applied art embrace designs and models, tapestry, embroidery, stone and wood carving, cabinet work and upholstering, ceramics, gold and silversmiths' work, metal work, chasing, repoussé, saw-piercing, wrought iron work, &c. The master of the Guild, Mr. T. Swaffield-Brown, delivered an able address on "Art as Applied to Local Manufacture."

Nearly two years ago the Admiralty sanctioned experiments in long distance signalling at sea with a diamond-shaped apparatus, the joint invention of Capt. Prince Louis, of Battenberg and Capt. Percy Scott; but when it was found after several trials on the gunboat Insolent that the mechanism could only be worked with considerable manual strain, permission was given to experiment with a collapsible drum, the invention of Rear-Admiral C. G. Fane, who was at the time admiral-superintendent of Portsmouth Dockyard. The *Naval and Military Record* says that in consequence of the success of the apparatus, which could easily be worked in a high wind, it was fitted to several ships and tested against Rear-Admiral A. K. Wilson's masthead semaphore in last year's manœuvre. The reports have since been under the consideration of the Admiralty, who on Saturday intimated to the Portsmouth Dockyard authorities that in future the semaphore is to be fitted to all seagoing ships.

A statement from the Board of Trade showing the production and consumption of coal and the number of persons employed in coal production in the principal countries of the world in each year from 1883 to 1894, so far as the particulars can be stated, has been issued as a parliamentary paper. In 1894 the United Kingdom produced 188,277,000 tons, Germany 76,741,000, France 26,964,000, Belgium 20,534,000, Austria 9,573,000, Japan (1893) 3,371,000, and the United States 152,448,000 tons. Of the British Possessions, Canada produces between three and four million tons, and in addition imports about half her total consumption, principally from the United States. New South Wales produces about three and a-half million tons, but, unlike Canada, her output has been of late years practically stationary. New Zealand yields over 500,000 tons per annum, but shows little or no increase. Natal's output rose from 26,000 tons in 1889 to 141,000 in 1894. Similarly in British India the production has steadily risen from 1,316,000 tons in 1883 to 2,821,000 tons in 1894. The countries which import coal in excess of the amount they export are Russia, Sweden, France, Spain, Italy, and Austria-Hungary; and of British Possessions, Canada, Victoria, Queensland, Tasmania, New Zealand, the Cape, and British India, together with all the minor Colonies, with the sole exception of Labuan—Borneo.

Dr. Stevenson Macadam, Professor of Chemistry in Edinburgh, gave evidence on Friday last before Mr. Mundella's Committee on Petroleum, and expressed a strong opinion that no oil used for illuminating purposes could be considered safe which had a lower flash-point than 100 deg. Fah. close test. He would not, indeed, prohibit the sale of oil with a lower flash-point, but would insist upon its being labelled, so that the public who used it should know that they were dealing with an oil which was attended with danger. He mentioned that by abstracting 10 per cent. of the spirit from the American oil it could be brought up to the flash-point which he recommended without any difficulty, and that the cost of this process would not amount to more than ¼d. per gallon. On the question of the danger from lamps, the witness differed from previous witnesses like Lord Kelvin, in that he preferred a strong glass to a metal reservoir, because experiments which he had conducted showed that the metal reservoir raised the temperature of the oil considerably more. He had never known any accidents take place from the vapour thrown off by Scotch oil. The chairman pointed out that in France and Germany oil was sold at 70 deg. flash-point, and there were comparatively few accidents. Dr. Stevenson Macadam said he would still insist upon the 100 deg., and that if there were fewer accidents in those countries it was probably due to the higher intelligence of the people. Mr. Alex. Cross, a Scotch member of the committee, remarked that he was sorry to hear such a statement from a countryman of his own. The chairman said he might be sorry, but he was afraid the statement was only too true. The committee adjourned.

The Water Committee of the London County Council, in a report which has just been issued, state that under the standing orders of the Council, unless their recommendation is brought up by the 9th inst., the Council well not be able to initiate any legislation with regard to the water supply in the coming session. The Council cannot let this water question alone, or cease wasting the ratepayers' money on futile schemes of no use to anyone except those concerned in the spending or receipt of this money. It is not, however, true that the committee has proposed to go either to Loch Shin, Loch Katrine, Loch Erne, or Loch Derg, but "without desiring to prejudice the position of the water board proposed in the Government Bill, the committee nevertheless could not disregard the possibility that the Government Bill might not become law." They therefore recommend the Council to go forward in the matter of a supplementary supply from the Welsh water areas. Certain engineering and other details in connection with the scheme might require reconsideration. The committee have engaged the services of two eminent engineers, whose opinions will in due course be reported. The committee formally recommend the Council to pass a resolution authorising application to be made to Parliament in the ensuing session for power to bring additional supplies of water to London from the watersheds of the Usk and Llangorse, upon the lines of the report of the Water Committee as approved by the Council. The committee add that on the subject of the future supply of water to the metropolis they could not disregard the question of the purchase of the existing water undertakings, but for the present they consider it sufficient to recommend that a Bill or Bills should be prepared for introduction in the session of 1897 for the purchase of the undertakings of the eight metropolitan water companies.



TRIPLE-EXPANSION PADDLE ENGINES OF THE SOUTHEND BELLE

MESSRS. DENNY AND SONS, DUMBARTON, ENGINEERS

(For description see page 596)

FOREIGN AGENTS FOR SALE OF THE ENGINEER.

AUSTRIA.—GEROLD AND Co., *Vienna.*

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

S. D. (Dorking.)—*You will find in our portfolio of working drawings a complete set of Cornish engine work. For the rest we should advise you to consult the back volumes of* THE ENGINEER, *which you can do on application to our publisher.*

D. C. M.—*The facts are precisely as stated in our article. The flange rail succeeded the cast iron rail. You write as though the flange rail had been given up for no reason whatever. The American rail is carried on hard wood sleepers. Do you suppose it would pay our companies to import hard wood and revert to the flange rail? If so, why not produce your figures, and let the question be dealt with on the proper pecuniary basis.*

A YOUNG ENGINEER.—*The effective brake radius is measured from the centre of the fly-wheel to the centre of suspension of the weight, not to the rim of the fly-wheel. The virtual diameter of the brake wheel was more than 3ft. judging from your sketch. We should say that the foot-pounds per revolution were 330. This would give for 250 revolutions per minute 2·5 H.P. It is not at all unusual for small gas engines, which have been at work for some time, to give a brake horse-power only half of the indicated. But it is not every one who can indicate a gas engine accurately. You say nothing of the number of explosions per minute.*

IRON MOULDING.

(*To the Editor of The Engineer.*)

SIR,—Would you or some of your learned readers kindly inform me when "Iron Moulding" was introduced into Great Britain, by whom, and where; also when, and in what part of the world was the art first discovered, and much oblige. IRONFOUNDER.

June 8th.

STRAW BOTTLE CASES.

(*To the Editor of The Engineer.*)

SIR,—I shall be obliged to any reader who will give me the address of makers of machinery for producing cases of straw for bottles. J. H.

June 9th.

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number)	*£0 14s. 6d.*
Yearly (including two double numbers)	*£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate or any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—	
Half-yearly	*£0 18s. 0d.*
Yearly	*£1 16s. 0d.*
THICK PAPER COPIES—	
Half-yearly	*£1 0s. 3d.*
Yearly	*£2 0s. 6d.*

READING CASES—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

ROYAL METEOROLOGICAL SOCIETY.—Wednesday, June 17th, at 7.30 p.m.: Papers to be read, "Arctic Hail and Thunderstorms," by Mr. Henry Harries, F. R. Met. Soc. "Climatology of Valencia Island, Co. Kerry," by Mr. J. E. Cullum, F. R. Met. Soc. The following Paper will probably also be read, "The Winter Climate of Egypt, based on results from self-recording instruments, 1893-96," by Mr. H. E. Leigh Canney, M.D.

THE ENGINEER.

JUNE 12, 1896.

THE DEFENCE OF THE EMPIRE.

WE give elsewhere an abbreviated report of a paper read by Admiral Colomb "On the Function of the Army and Navy in the Defence of the Empire," which deserves attention, not only on account of the subject itself being of the first importance, but also because the author is specially capable of grasping the question, and because the audience contained many high authorities on the matter brought under consideration.

The main object of the paper was to urge that dependence should be placed on mobile sea and land forces rather than on fortified positions—in fact, that we should depend on throwing a large force on to any point attacked rather than in rendering each point independently strong; that a Power that expended its strength in fortifying all points divided its strength, and that an equally strong Power that mustered all its forces to attack would successively overcome all the positions of the former. As a general principle to be kept in view, many of us will agree with the Admiral. Most of us will concur with him in urging the need of grasping the question of National Defence as a whole, and wish, with Sir Lintorn Simmons and other speakers, that a strong Commission were appointed to deal with this question. When we come to practical steps the difficulties arise. Admiral Colomb clearly objects to fortifying London. There he joins issue with a considerable body of scientific officers, especially Royal Engineers, by whose advice some actual steps have been carried out, perhaps unknown to the public generally, and a first commencement has been made of a system of the very unobtrusive defensive works which are now found most effectual. The Admiral certainly did well to withdraw, as we understand it, his classification of the schools of defence as "instinctive" and "reasoned." Our leading Royal Engineer officers are hardly likely to be won by being told that reason is now to be opposed to their instinct. Reason is the attribute of a man, and instinct of a beast. We are quite sure that the Admiral did not intend to call our military advisers beasts, and we are most anxious that it should be understood that he disclaimed any such deduction, however obvious. Nevertheless, we think that the Admiral's condemnation is too vague and sweeping. He practically puts the great wall of China and the Paris fortifications into the same category. On this principle it might be urged that a position possessing the advantage of interior lines, so that it can concentrate on any point more quickly than its enemy, is in the same position as an army surrounded and hemmed in. Proportion and circumstances make all the difference, and we would remind Admiral Colomb that it was the first Napoleon, whose grasp of warfare was peculiarly startling and bold, and who wielded his forces with singular unity of purpose, who fortified Paris. The Admiral will doubtless reply that this line of action was Napoleon's notorious mistake, and that when he at length fell back before the allies he exhibited it in another shape in weakening his army by leaving forces clinging to fortresses which were bound to yield in succession when his main army had been rendered too weak to recover lost ground. The opposite action, however, is illustrated in a measure when Napoleon returned from Elba and found most of his old forces available again for such a blow as Admiral Colomb would probably commend when he aimed by mobile forces in the Waterloo campaign to strike in detail armies which, when all gathered throughout the Continent, would become irresistibly strong. The fact is that in both cases Napoleon was overmatched in whatever line he followed, and it is difficult to argue positively on the question. The defence of Paris certainly gave the Germans more trouble and anxiety than was generally known in England at the time, so it now appears, but how far this was due to actual guns and earthworks may be questioned. Admiral Colomb would doubtless attribute it to the difficulties he pictures connected with the attempt of a general to attack unfortified London. Leaving this, we may turn to the next practical application of the principles we think the Admiral suggests, namely, the substitution of active for reserve forces. If this means that a given sum of money be taken from volunteers and given to establish regular forces, we entirely disagree with him; but we cannot think that this is meant, as it would cripple the very object the lecturer had in view. At least 1000 volunteers would be sacrificed to obtain 100 regulars, and a very limited application of such a process would soon bring down our forces to such numbers that we should be unable to allow any of our regulars to leave the kingdom, which is the last thing desired by the Admiral. The same difficulties in detail beset us in dealing with foreign stations. We understand that guns and a sufficient force are advocated to prevent surprises, but not for prolonged defence, because eventual safety is to be secured by the arrival of a mobile force. So far we agree with the Admiral, but for safety against surprise, we need some kind of works round the guns, and some force of men, otherwise, in most cases, the enemy would land and take us in reverse. So again with our own defended ports, Admiral Colomb himself says that no consideration of leaving "places behind him" "insufficiently fortified and garrisoned "would deter an Admiral from striking at any equal or inferior force within reach." He could hardly more completely establish the necessity for pretty strongly fortified and garrisoned ports, for the only case in which they could be dispensed with is that when it was absolutely certain that the "equal or inferior" enemy was the only possible one, or else very inferior indeed. Could a defenceless general regard with equanimity the sudden surprise of even a moderate force that had by any means eluded the British fleet; or even suppose the fleet to have returned after fighting an "equal" one, would it be in a state to defeat any enemy subsequently arriving?

If the enemy's force takes the form of men-of-war escorting transports of troops, the Admiral thinks that tugs and almost any craft might act as rams. Can he mean that all these dart out animated with one mind, and, reckless of danger, dash in numbers at the enemy? We think it would be madness to reckon on such action—unheard of so far as we know. The English ships doubtless did something that loosely might seem like this, when the Armada swept up the Channel; but our ships possessed such speed, and were so handled, that they fought with comparative immunity. They were manned by the pick of our seamen. The tugs and craft left behind by our forces ramming with the prospect of almost certain destruction, are in a totally different case. Moreover, the commander of an attacking expedition would surely have quick-fire guns disposed to defend his ships in such a way that, for a time at all events, any tug or unarmoured vessel approaching would be doomed to certain and instant destruction. The English sailors under Essex, Drake, and Raleigh gathered increased audacity from the immunity with which they made their attacks. We fear that our captains and crews of tugs would witness sweeping destruction falling on all who first ventured near the enemy's transports. We question if this condition of affairs seriously entered Admiral Colomb's calculations as actually arising. We think that the general superiority of our naval forces is too present to his mind; but can such general superiority, which may be very limited in certain combinations, ensure the non-existence of some local temporary superiority? Generals cannot be blamed for questioning it. Engineer officers may also urge that forts cost very little compared to ships, and are permanent, while ships wear out. Thus a selfish view suggests that it is best for our fathers to have spent money on forts and for us to spend it on ships, and this, in a measure, is realised in the present condition of things.

On the whole, we agree with Admiral Colomb in broad principles, and we agree with him and other speakers that the question of national defence should be seriously taken up; but, for the practical application of principles, it is necessary that a very able and strong Commission should be appointed to sift the matter as it can only be sifted in a time of peace. If the paper helps in bringing about such action we shall be greatly indebted to Admiral Colomb.

QUACKERY IN ENGINEERING EDUCATION.

IN the United States, as in this country, are to be found engineers who lift up their voices and protest against the Technical College, its ways and its methods, its works and its claims to greatness. An amusing article, by Professor Edward Kidwell, appears in the last issue of the *Engineering Magazine*. He has taken for his text, "Quackery in Engineering Education." He hits hard and spares not; uses rather strong language, and produces an effective picture. He has singled out as the deplorable example no less important a person than Professor Thurston; and we are not surprised to find that the Editor of the *Engineering Magazine*, in a foot-note, "invites perfectly frank and free discussion of the subject here broached, alike from those engaged in educational work, from college graduates, and from practical men." Possibly Professor Thurston will take up the cudgels in defence of his views. Mr. Kidwell's case is, however, so strong that it will not be easily broken down. By the word "quackery" he tells us that he means "any promise or pretence to do that which cannot be done, either because the thing itself is impossible or because he who made the promise knew that the means to execute it were wanting." He goes on to show that the trustees of a technical school are not as a rule qualified to select teachers; and he holds, to put matters in plain phrases, that the technical schools too often obtain pupils by making statements which are not true. In proof he quotes an utterance of Professor Thurston to the effect that a pupil may be made a good smith by a few days' work, and that "in wood working and machine shop practice he may soon learn to handle tools like an old hand." We find it difficult to believe that Professor Thurston could have made such statements seriously; but it is beyond question that he has done so. "If the terms mean the same to Mr. Thurston that they do to engineers and mechanics, then they furnish an example of exaggeration and bad logic. They are not true and never can be," says Mr. Kidwell. This is hitting Professor Thurston pretty hard, but he certainly deserves it. Mr.

Kidwell pushes the indictment home. He writes succinctly, and uses no more words than are necessary. His arguments are, therefore, all the more cogent and convincing.

We have so often written on the same subject, and to much the same effect, that it might almost seem that nothing more remains to be said. Fortunately, however, there is some evidence, growing, too, daily in strength, that the tide is turning, and that common sense is beginning to assert its power and have its way. Such an article as that from which we have quoted is a case in point. Mr. Kidwell is himself a teacher of engineering in a college, and knows very well what a college training can and cannot do. He speaks with authority. In this country more than one professor of engineering has insisted on the adoption of rational methods of instruction; and has refused to sanction the issue of exaggerated claims. Nor is this all. There is manifest elsewhere than in engineering schools a tendency to regard even the higher education as a means to an end, not as the end itself. It begins to be understood that life is too short to make it safe to spend years in the acquisition of useless knowledge. A noteworthy example of this is afforded by the consideration which is being given by the College of Physicians to a proposal that the character of its examinations should be modified in a way to concentrate the maximum effort of the student on the acquisition of that species of information likely to be of most use to himself and his patients in after life, instead of wasting time in learning for the purpose of passing his examinations that which he forgets immediately afterwards, simply because he is never called upon to make the smallest use of it. Mr. Kidwell does not appear to think that anything is properly taught in technical colleges. We certainly shall not go so far, at least as regards this country. The defect inseparable from college training is one for which the professors can scarcely be held responsible. It is that no importance whatever is attached to the commercial aspect of any form of engineering science taught. In actual life, however, the mechanical and the civil engineer alike have to study economy in designing and carrying out their work. Of this truth the professor, so far at least as our experience goes, takes no account. Of two designs, for example, the professor will regard one as better than the other on grounds which have nothing in the world to do with the cost of production. Of course the engineering firm that followed this practice in daily life would find itself in the Bankruptcy Court in a few months. As we have said, we do not hold professors responsible for this, because it is quite out of the question that they should impart more than the rudiments of the science of engineering economics to their pupils; but we do hold them responsible if they assert that the young men to whom they give diplomas are fully trained mechanical engineers. The scientific and theoretical man continually finds that the question of cost in any structure is quite as important as the question of strength; and that he who can produce a given result with the smallest outlay is, as a rule, the most competent engineer. Nor does this apply merely to the machine made. It holds good of the working of the machine. Let us take as an illustration a rotary cutter shaping machine. The first point to be considered by the draughtsman in designing such a tool is that it may be made to bring in the largest possible profit to the firm constructing it. Incidentally, we may add that this it certainly will not do unless at the same time it gives satisfaction to the purchaser—the person, that is to say, using it. Now, it is easy to see that a skilful designer, working with a view to profit, will so arrange matters that the first cost of his patterns shall be small, and that the moulding work to be done in the foundry shall involve the least amount of labour. So far so good. But the designer must not only do well up to this point, he must bear in mind that while saving work to the pattern-maker and the founder, he may be inordinately augmenting the quantity of machining to be done subsequently. He must not "rob Peter to pay Paul." Assuming that he has got over all these difficulties, it may nevertheless easily happen that the net result of his labours is a machine which cannot turn out work as cheaply as it ought. Thus, it may be too slow in its movements; and the arrangements for securing and adjusting work on the tables may be bad in the sense that they are tedious in their action, or involve much setting and resetting before the work is properly adjusted. As a matter of fact, the slow and costly tool, embodying in itself every commercial fault, may be able to turn out consummately good work. It may be strong, durable, and consume little power. Now, in the eyes of the professor, it would for these reasons be perfect, because one set of conditions would for him be eliminated. The price of the tool would affect him in no way. The cost of the work turned out by it would not even interest him; and herein lies one great difference between learning to design machines in the college or the technical school, and learning to design under the eyes of the competent head of a real drawing office. Therein the pupil finds that a sheet of paper and a pencil are the cheapest appliances with which it is possible to obtain information about proposed machines; and that ten hours of a draughtsman's time are well spent if they result in the saving of even a sovereign in the construction of each machine made from his drawing. We have said that we do not hold the professor of engineering responsible. Possibly in this some will think that we go too far. Certain it is that there are professors who maintain that it is practicable, even in a technical school, to teach engineering under conditions which, up to a certain point at least, shall be as practical as can be desired. But do we not also find that such men are constantly thwarted and opposed, checked and limited by trustees and governors, who really cannot and do not possess the information essential to the formation of a sound judgment as to the merits or demerits of the teaching staff? We have one noteworthy case in mind at this moment, and we know that in others the professors have had to give way with reluctance and against their own better judgment.

The pity of it all is that, of course if properly used, the technical college is capable of doing admirable work. Indeed, within its walls can be taught much of great value that can be acquired nowhere else save with infinite pains and trouble. But to this end the professor of engineering and the demonstrator must never forget that all that they can teach amounts to little more than an introduction to the finished art of engineering; that the time of tuition is short, and that none of it must be wasted in imparting useless information. On this last point Mr. Kidwell is at once energetic and amusing in no ordinary degree. He quotes the information, for example, supplied in one college to the student concerning hemlock spruce fir, which is mainly botanical, and largely inaccurate, and goes on to say, "The *habitat*, metric measurement of the cones, and configuration of the leaves may be very important to somebody, but what an engineer wants to know is that hemlock is a rather hard, extremely brash, and treacherous wood, liable to crack open in rings, and is usually so wind shaken that the interior is a mass of splinters; hence the wood is used in only the most inferior class of structures, and in some localities is not considered worth cutting for the market even for firewood." There are two essentials to success in teaching engineering. The first is that the professor should know how to teach, and the second is that he should know what to teach. We believe, and we hope that the day is not distant when the true functions and position of the engineering college and technical school will be understood. Then, and not till then, will they do the excellent, if limited, service of which they are capable.

THE LONDON DOCK COMPANIES AND SHIPOWNERS.

A short time back the daily papers were full of letters discussing certain new rules that the associated London dock companies proposed as to the overside discharge of vessels. These proposed rules, which would practically have the effect of stopping unloading into barges of goods destined for the outside wharves and warehouses, were received with vigorous remonstrances by all concerned in the import trade of London. Apparently the dock companies realised that it would be impracticable to put their proposed rules into force. At all events, the subject seems to have been removed from public discussion, and it has been generally understood that the new code had been withdrawn. But a fresh departure has now been taken by the Dock Association Board which proves that its intention was simply *reculer pour mieux sauter*. This body has given notice to the shipowners customarily using the several docks in the Thames to terminate an existing agreement with them—entered into, we believe, shortly after the now historic strike of the dockyard labourers—whereby the privilege was accorded to the shipowners of employing their own labour force for the loading and discharge of cargoes, as well as that allowing the larger lines to have fixed berths for their fleets. The agreement to this effect was terminable by the dock companies on their giving six months' notice. This has now been given, and we understand that the privileges named will come to an end about the end of August or beginning of September next.

The step thus taken is said to have aroused a very bitter feeling among the shipowners. They feel, it is rumoured, that the action proposed by the dock companies has been due to an adverse feeling arising out of the belief that the measure at first proposed had been defeated for want of full support by the owners of shipping. It is also rumoured that the latter had promised that support, but that this had been withdrawn when the storm of remonstrance to which we have referred found expression. With this aspect of the question, however, it is not our province to deal. But what we have concern with is the consideration as to how far measures under contemplation may be likely injuriously to affect the trade of London as a maritime port. As in all cases there must be, there are two parties chiefly concerned in this present quarrel. On the part of one of these, the dock companies, it is urged that their shareholders must live, and that by some means or other a dividend must be earned for them. On behalf of the other party, the shipowners, it is contended that while not denying the legal right to give them the notice tendered, the effect of it must be to dislocate all their arrangements, and to force upon them the raising of freights at a time when competition by the foreigner weighs heavily against the successful sailing of vessels under the British flag. Both parties to this dispute are possessed of certain powers for attack or for retaliation. The London dock companies form a monopoly, unfortunately a somewhat impecunious monopoly. These, therefore, are possessed of the whip-hand in the present dispute. But competition with them, it must be remembered, is not confined to the Thames. Southampton and other large shipping centres would go far in liberal concessions to re-attract services that formerly patronised their docks, but have of late years abandoned them for London. It would, therefore, not be surprising to hear that negotiations with these might result in the re-transfer of much profitable business from the central to the outer ports. Should this occur, the dock companies will have killed the goose that laid their golden eggs, while serious injury will have been done to the prospects of the Thames as a resort for shipping. It will be as well to quote some figures illustrative of the extent to which the shipowners of London may be affected by the withdrawal of their existing privileges. It is the custom of the dock companies to charge shippers about 1s. 6d. per ton for expenses on discharge of cargo. The tariff published by the dock companies as that they will enforce when this business comes again into their hands, varies for different classes of goods between 3s. 6d. and 4s. 6d. per ton. Taking one article in illustration, tea, we find the tariff for this to be 4s. Now the tea shippers of Calcutta have, we have been informed, a running contract for tea freights extending for five years. During the remainder of that period yet to run, it therefore follows that the shipowners will have to lose on that particular item of freight no less than 2s. 6d. per ton, a loss for which they will have no power to obtain reimbursement. Surprise can scarcely be felt that in anticipation of such a direct loss, the ship companies may decide on very serious steps to avoid its incurrence.

But although we have space only to quote this single instance, it is palpable that there must exist many other interests that will become largely affected by the new rules and their accompanying new tariff. Indeed, we must presume that to meet the extra charges on cargo after arrival in the Thames, the 2s. 6d. we have named must be met by a corresponding rise in freights to London generally. What this would mean to British producers throughout all the dependencies of our Empire will easily be realised. If it has been the intention, as has been surmised, that the shipowners should be "put in a hole," the dock companies have certainly succeeded in doing so. Whether it may be worth their while to face the risks of retaliation that we have pointed out must be a matter for them to consider and decide. We have been told that the executive of the associated dock companies are fully alive to the dangers that the latter are incurring. But they have before their eyes a threat, which is said to take the following form: "If our present management does not secure a dividend, we must get one that will." This threat opens up a further consideration in our theme. We have referred to the dock companies of London as being an "impecunious monopoly." Were it not so, no such ill-considered threat as that above recorded would have been made on its behalf. Now we fear there is little sympathy felt with the dock companies in their present position. Almost from the first their history has been a record of extravagance, the result of which has been that they are for the most part incapable of earning good dividends. We believe it is now over forty years since the Shadwell Basin was constructed. This one work will suffice as an instance of the line of action that has brought the dock companies to their present position. The site of that basin was, when acquired, densely populated. We fear to state what it cost for purchase and compensation. Men of that day stood aghast at the outlay the selection of such a site involved. Several of these, and notably the late Mr. Bidder, saw the mistake that was being made, and quietly purchased for what was relatively a mere trifle the waste land now the site of the Victoria Docks. As little outlay was made as might be sufficient to provide the proposed accommodation for shipping, timber being almost solely used in furnishing this. But it sufficed for the object in view, and, while the Victoria Docks were largely resorted to, the costly accommodation provided higher up the river was without customers, the monopoly of the older companies was endangered, and the result was—as Mr. Bidder and his astute fellow adventurers had foreseen—that the Victoria Docks were bought up at about three times the amount of their first cost. In this and similar ways millions have been spent in providing the present dock accommodation in the Thames. We are telling, we know, but what is an old and oft-repeated story; but it has been too much the case that it has been lost sight of. It is legitimate that the dock management should endeavour to earn a dividend—even a good dividend—but it must not be forgotten that the attempt to earn the latter may inflict irreparable injury on the port of London.

WANTED, THE REASON WHY.

As information is acquired concerning natural phenomena, it becomes more and more evident that many of our most treasured theories and explanations will have to be thrown on the scrap-heap of scientific hypotheses. The researches of Lord Rayleigh, in argon and helium have already demonstrated that there is much in the received molecular theory of gases that will have to be rejected as untrue. The Röntgen rays have done the same for light, and now Professor Dewar has shown that as yet nothing like a satisfactory theory of electricity and magnetism has been framed. The Friday evening discourse last week at the Royal Institution was delivered by Professor Fleming, and was mainly a statement of the very remarkable results obtained in the course of a series of experiments carried out by himself and Professor Dewar on electrical conduction at low temperatures. It is not too much to say that these results go far to upset all our preconceived notions, and tempt us to ask if the phrase "conservation of energy" conveys any adequate idea whatever of any natural processes. Thus, for example, Professors Dewar and Fleming seem to have established that a pure metal at absolute zero would have no electrical resistance, so that the smallest filament could carry the most enormous conceivable current without being heated. Some time since we stated that it was quite conceivable that a magnetic screen might be produced, and that if it was produced we should be within measurable distance of perpetual motion; in other words, of a machine which could work itself. Professor Fleming stated on Friday night that a pure metal at the absolute zero would form an absolutely opaque screen to electro-magnetic radiation. But the whole lecture bristled with statements going to show that there is no apparent connection between causes and effects, and that the expenditure or not of energy in the performing of processes is brought about in ways of which we know nothing. For instance, it is impossible to send a current of electricity along a pure metal at normal temperatures without loss of energy. We have only to bring down the temperature to zero, and the loss of energy ceases. What is the connection between heatin the wire cone and the expenditure of energy? As the years roll on science seems to drift closer and closer to the rocks of agnosticism; and the man who studies and experiments most will in the end be he who knows least.

PETROLEUM IN THE UNITED STATES.

An increase in natural oil production means so much that is good for makers of drilling and boring machinery, of piping, of oil-pumping machinery, of oil reservoirs, of tank steamers, oil-refining machinery, and of other constructive work, that it will be deemed excellent news which reaches England this week from the United States. We refer to several new developments in the oil fields of Kentucky.

Operations have, indeed, been so extended as to induce a general belief in America that the southern section of that State will develope an oil field that will rival the northern territory in its richest production. Interest in Kentucky oil land, especially in the valley of the Big Sandy and the eastern counties, is increasing, and very liberal terms are being offered for leases at many points. It is now believed that two-thirds of the State of Tennessee, with its 46,000 square miles, is a magnificent oil-producing section. The belt is simply the southern end of the famous Pennsylvania, West Virginia, Ohio, and Kentucky oil fields. Quito recently the Standard Oil Company secured control of 95,000 acres of land near Sunbright, in addition to the large quantity of land which it already leases. This Company now owns upwards of 700,000 acres of land in its own right, and has secured leases on more than 1,000,000 acres besides, and has just decided to spend a million dollars—about £200,000—in a new pipe line from Burnside, Kentucky, to Allgood, Tennessee. It is also erecting three iron storage tanks, capable of holding 120,000 barrels of oil each, at East Port, Pickett county. Statistics just issued show that the average daily production in April of the whole of the famous Appalachian oil region, compared with the previous month, had increased from 87,188 barrels to 97,308 barrels. The output of that region in April reached 2,883,569 barrels, or an improvement on the previous month of 204,248 barrels. Stocks in the whole of the Appalachian field have increased to 6,697,480 barrels, or an increase of 691,748 barrels over the month previous. Though American engineers will get the most, English firms will certainly share with them a portion of the orders which these developments entail.

"DEAR OLD SMOKY SHEFFIELD."

DOES Sheffield really enjoy its smoke? The question is suggested by the lack of enthusiasm over the Pure Air Fund, started by the *Sheffield Daily Telegraph*, and headed by the proprietors of that paper. The fund was preceded by pressing appeals for smoke abatement, and a series of carefully-written papers by an engineering expert, showing that smoke could be greatly lessened, and was indeed being almost abolished, in many of the Sheffield establishments. It was not necessary to demonstrate, for it was matter of common knowledge, that the Sheffield Corporation literally let the nuisance alone. An occasional prosecution only served to remind the public that there were laws against excessive smoke-making, but when the local authorities did secure a conviction, the penalties imposed were so small as to be practically powerless to help the fight for pure air. That being so, the Pure Air Fund was started. At this moment, after weeks of work, many columns of urgent writing and of explanatory special contributions and drawings exhibiting the ease with which smoke can be dealt with, the total amount of the fund is only slightly over £200, of which £100 is given by the newspaper which originated the enterprise, and Messrs. Walker and Hall, a silver firm who have been active in efforts to put down smoke. The result is a distinct disappointment. It is the custom sometimes for Sheffield people, even in public, when they are in a mood of local patriotism, to speak lovingly of "dear old smoky Sheffield." Can they really mean it? They certainly show no zeal to get rid of the gloom and its accompanying grime. Is it possible they like it, as the Scottish dame did the dirt, because, as she put it "the dartier the cosier"? Sir Frederick Mappin, Bart., M.P., member for the Hallamshire Division, holds that the duty is not one for private enterprise but for the public authority. That may be one reason why the Sheffield people are so supine. No doubt Sir Frederick is right in laying the blame upon the shoulders of the local authority; but as the local authority is so careless of the general interest in this respect, it seems essential that some effort should be made to compel action. And, surely of the two evils, the greater evil is to leave it alone! It *will* be left alone, unless private effort goads the lumbering civil executive to action, and if the present movement is discouraged by cold counsel, Sheffield will remain, as it has ever been, in the words of Horace Walpole, "the foulest town in the fairest country I have ever seen."

LITERATURE.

A Treatise on Civil Engineering. By W. M. PATTON, author of "A Practical Treatise on Foundations;" formerly Professor of Engineering at the Virginia Military Institute; Engineer-in Charge of the Mobile, Ohio, Susquehanna, and Schuylkill River Bridges; late Chief Engineer of the Mobile and Birmingham, and the Louisville, St. Louis and Texas Railways; Consulting Engineer, Chicago, Illinois. First Edition. First Thousand. New York: John Wiley and Sons, 53, East Tenth street. 1895.

IN commencing his voluminous and comprehensive work, the author enunciates principles which we have always persistently and consistently recognised and advocated in our columns. Even in these days of cramming, the truth and importance of these principles are becoming more widely known and appreciated. If it were only engineers of the old school, "rule-of-thumb men," of which there are not very many left now, who condemned the vicious system of placing theory before, and at a height immeasurably above practice, there might be something to be said on the other side. But it is not so. As a matter of fact, engineers whose educational, scientific, and professional attainments are of the highest order, unhesitatingly set their face against the manufacturing of their younger brethren by sheer theory and book teaching. Like our author, we fully recognise not only the expediency but the absolute necessity of an "extended training in pure and applied mathematics," but also hold with him that the "important principles of engineering as a practical science should not be lost sight of." We have nothing to urge against the numerous so-called engineering schools and colleges. The education they afford is very good in its way when viewed from a purely theoretical point of view, but they undoubtedly do foster the idea—the serious error, which is very widely believed in by outsiders—that two or three years' attendance upon the classes of their professors, and the passing of an examination, turn pupils out not only as good, but far better engineers than if they had served their apprenticeship to a first-class firm, or their pupilage with a well-known civil engineer in practice. If there is one profession more than another whose proper motto is "*Facta non verba*," it is that of engineering.

The contents of the volume before us may be divided into three general heads, viz., theoretical, practical, and descriptive. "Articles," or as our publishers would put it, "Chapters" I. to IX. are devoted to the preliminary branches of the profession, and include surveying, ranging lines and curves, both on land and water, reconnaissances and locations. At page 45 there is a little confusion. The equation

$$r = w\frac{A\,C}{B\,C} \quad . \quad . \quad . \quad . \quad . \quad . \quad (31)$$

should read,

$$r = w\frac{B\,C}{A\,C};$$

and in the following line, for B C = 1 mile = 5280ft., read A C = 1 mile = 5280ft. This formula (31) is repeated in page 72, and quoted as stated in our correction. With respect to the system of American levelling Mr. Patton remarks, "Just here, however, is the only objection to this method of levelling. There is no method of correcting the error in readings, and incorrect elevations are often obtained. Consequently some engineers prefer the method of keeping notes known as the column of differences." We very much prefer the system of "some engineers." Building and constructive materials of every description are treated of in the following ten articles. It is universally admitted that there is a proper time of the year for felling timber, but unless there was an absolutely close season it would be futile to expect any attention to be paid to that particular detail. Both here, and on a far greater scale in America, where sudden demands for large-sized timbers are constantly occurring, when the material is required, it has to be procured. It matters nothing whether the tree be fit for felling or not; the sap may be literally oozing out, but it is cut down, sawn to the proper scantlings, and built up while as green as grass. It is a clear case of "*force majeure*," which, however regrettable, is equally unavoidable. It is well remarked under "Cast Iron" that "it is better far to specify what properties the material should possess than to describe modes and methods of producing those results; for however instructive and interesting may be the methods of producing the many and varied castings of all kinds, it is more important to be able to determine their good and bad features." The mere breaking test of iron, irrespective of other circumstances, is known to be alone no criterion of either its quality or strength. In Article XXI. we pass on to structures, equilibrium of forces, bending moments, and the resistance and strength generally of beams and girders. The definition, or rather the distinction, between "stress" and "strain" is scarcely so clear as it might be. It is not apparent whether the stress produces the strain or the strain developes the stress. It is important that these two should not be confounded, although it is but a little while since they were employed as nearly synonymous terms in numerous text-books and scientific works. It is stated that "for every kind of strain produced there is developed a corresponding stress," which might incline one to the conclusion that the strain is the cause of the stress. The generally received order of procedure is as follows:—Loads or weights on a structure of any description produce stresses in the various members, which are attended by slight deformations or alterations of form, which usually result in a lengthening or shortening of the members. These elongations and compressions constitute the strain which is developed by the stress itself. Our readers may expect to find that many details, the working out of practical and theoretical questions and problems, are treated in a somewhat different manner to what they are accustomed to find in English text-books, and in connection with this remark, it may not be superfluous to some of them to point out that in determining the coefficients of elasticity, the formulæ,

$$E = \frac{5000}{1/3206} = 16{,}030{,}000 \text{ lb.}$$

would with us be written

$$E = \frac{5000}{\frac{1}{3206}} = 16{,}030{,}000 \text{ lb.}$$

At the same time it should be stated that the former method of indicating a fraction is common among continental engineers. Indeed, we use it ourselves, when we employ small fractions of the monetary and other units. In Article XXXII. "Moments of Inertia" are dealt with, and as they are sometimes a stumbling-block to beginners and young engineers who do not exactly see the necessity for them, as admitted in the article, they are treated with great care and in an exceedingly lucid and explanatory manner. The "Deflection of Beams" introduces us to our old friend $E\,1\,\frac{d^2y}{dx^2}$ and to the equations connected therewith, from which all the problems relating to deflection can be satisfactorily solved.

The practical part of the "Treatise" may be said to commence with the article on "Construction," in which the application of the principles previously enunciated is carried out in the design and construction of the foundations of engineering works, all on a scale of considerable magnitude. Among American engineers the open-crib process for getting in foundations has always been a favourite one. It was used in the building of the pivot pier of the swing span of 520ft. in length of the Interstate Bridge. This span is stated to be the largest of its kind at present in existence, and to exceed by 15ft. that of another similar structure in the States. For the purpose of illustrating other practical and also important details attached to possibly the most arduous and anxious part of the duties of an engineer, the Memphis, Poughkeepsie, Washington, East River, St. Louis, Susquehanna, and Ohio Bridges have been quoted. It is but fair to state that the author has not restricted himself solely to examples of works in his own country, but has also described the methods employed in the Forth and the Tower Bridges, and in the Amsterdam and North Sea Canals. Retaining and reservoir walls, dams, and weirs, arches of masonry and concrete, are fully treated of, both theoretically and practically, and constitute a large, interesting, and very readable part of the volume. "Tunnels" have an article to themselves, and as in the case of the foundations for bridges, numerous examples are quoted from nearly every country in the world. Under the title of "Framed Structures," the loads upon trestles and supports, their shearing and bending moments, the stresses upon iron piers, and in roof and bridge trusses, are investigated both graphically and analytically. Examples are given of some of the almost innumerable different forms of trusses affected by American engineers, of which the favourites appear to be the Howe and the Pratt types. As the former, with the exception of the vertical tension rods, is built entirely of wood, it is not adapted for long spans, and, in fact, has been greatly superseded by its rival, the Petit truss. A modified form of this truss was proposed for the Channel Bridge. The concluding portion of this "Article," relating to the "Amount and Distribution of Live Loads," should be read with attention, as it states this much-vexed question with practical fairness and frankness.

The "Designing of Simple Trusses" supplies all the data for bridges, whether highway or railway, although they cannot all be classed under the category of "simple." It is a thousand pities that the form of the bridge which, except in America, where the suspension principle still continues to hold its own, promises to prove the most economical for great spans, should be so excessively unsightly. No treatise on engineering would nevertheless be complete without some reference to and description of it. Cantilever bridges are *par excellence* those best adapted for erection by "building out," as it is termed. We must differ from our author in a remark he makes in his article on designs of bridges. Referring to riveted truss bridges, he observes: "They are often considered stiffer and safer than pin-connected trusses. The secondary stresses developed cause these trusses to be less satisfactory than pin-connected trusses." We will not dispute for the moment the theory respecting the secondary stresses, although we do not concede it unconditionally. But we are aware of more than one example, the Crumlin viaduct to wit, both at home and abroad, in which pin-connected trusses have, through the medium of gusset pieces and cover plates, been converted into riveted trusses. We cannot call to mind a single instance in which the rivets in a riveted truss have been cut out, and their places supplied by either pins or bolts. The last 300 pages of this exhaustive volume are devoted to the different branches of hydraulic engineering, including a description of the Chignecto Ship Railway, which is, it is said, in actual progress, and also of the proposed similar undertaking at the Isthmus of Tehuantepec.

Mr. Patton's "Treatise" is valuable. It displays much research, a thorough acquaintance with both theory and practice, a careful selection of excellent examples and illustrations, and a candid and impartial regard for the opinions of other competent engineers and scientists, although they may, and do, in some instances, differ from those of the author.

In his preface, Mr. Patton acknowledges his indebtedness to his daughter, who, "during her leisure hours out of school, prepared nearly all the drawings in this volume," which amount to nearly 500 in number. We trust—*place aux dames*—we may be permitted to also acknowledge our indebtedness to the young lady. The type is very clear and good; the cuts and drawings, although necessarily on a reduced scale, come up well, and the publishers have ably fulfilled their *rôle* in introducing to the public a work which unquestionably brings the multifarious branches of civil engineering thoroughly up to date.

SHORT NOTICE.

Aluminium. The Aluminium Supply Co., 38, Victoria-buildings, Manchester. 1896.—This little book is sent out as a description of the aluminium products of the Pittsburgh Reduction Company's Works, where aluminium in castings, ingots, plates, sheets, tube, and structural shapes are made under the C. M. Hall Patents. The book contains all the information concerning the physical and mechanical properties of aluminium which would be wanted by anyone proposing to use the metal for any but exceptional purposes. It is so well done as a handbook in this respect and is so much more than a catalogue, that we notice it in this place; indeed, there is very little in it at all of the catalogue nature, not in fact so much as in many so-called text-books. It is entered at Stationers' Hall by Mr. A. G. Brown, the manager of the Manchester Supply Company, and author of the books on the indicator which we have favourably mentioned. Beside giving the properties of aluminium, it gives the properties of numerous alloys of this metal, and gives the comparative figures for the more commonly used metals, such as steel, iron, copper, and so on. For the sake of brevity in speaking and in writing the writer calls the metal alium throughout the book. In dealing with corrosion the author has mentioned most of the corrosive agents, but readers will have expected to find more, and unless they read through the part relating to solubility, will be disappointed. Most of that given under the head of solubility relates to corrodibility. On working aluminium in many ways the book is very instructive, and much more use is already made of it than is generally supposed. To complete the book tables of weights of the metal and other metals and alloys in rolled, cast, or drawn forms, are given, and to enable the designer of structures in aluminium to be independent of the older handbooks, tables of areas, circumferences, temperatures, and other frequently required figures are given.

BOOKS RECEIVED.

Applied Magnetism. An Introduction to the Design of Electromagnetic Apparatus. By J. A. Kingdon, B.A. London: H. Alabaster, Gatehouse and Co. Price 7s. 6d.

The London and South-Western Railway. Half a century of Railway Progress. By G. A. Sekon. London: published at 79 to 83, Temple-chambers, Temple Avenue, E.C. 1896. Price 2d.

An Analysis of the Accounts of the Principal Gas Undertakings in England, Scotland, and Ireland for the year 1895—being the twenty-seventh year of publication. Compiled and arranged by John W. Field. London: Eden Fisher and Co., or of the compiler, Horseferry-road, Westminster. Price 15s.

International Railway Congress. Fifth session. London. 1895. Question 1, Strengthening of Permanent Way in view of increased speed of trains. Appendixes of the first report—for non-English speaking countries—by Mr. Asp. Appendix to the list of questions. Technical information. Form A, the breaking of Steel Rails, by Mr. Bricka. Form B, the current cost of Metallic compared with Wooden Sleepers, by Mr. Kowalski. Form C, the Life of Wooden Sleepers of different kinds, not pickled, or pickled according to various processes, by Mr. V. Herzenestein. Form E, Locomotive Fire-boxes, by Mr. Hodeige. Form F, Locomotive Boilers, by Mr. Belleroche. Form G, Lubrication of Rolling Stock, by Mr. Hubert. Brussels: P. Weissenbruch, publisher.

NARROW GAUGE SELF-PROPELLED TRAM CAR

THE DAIMLER MOTOR COMPANY, LONDON, ENGINEERS

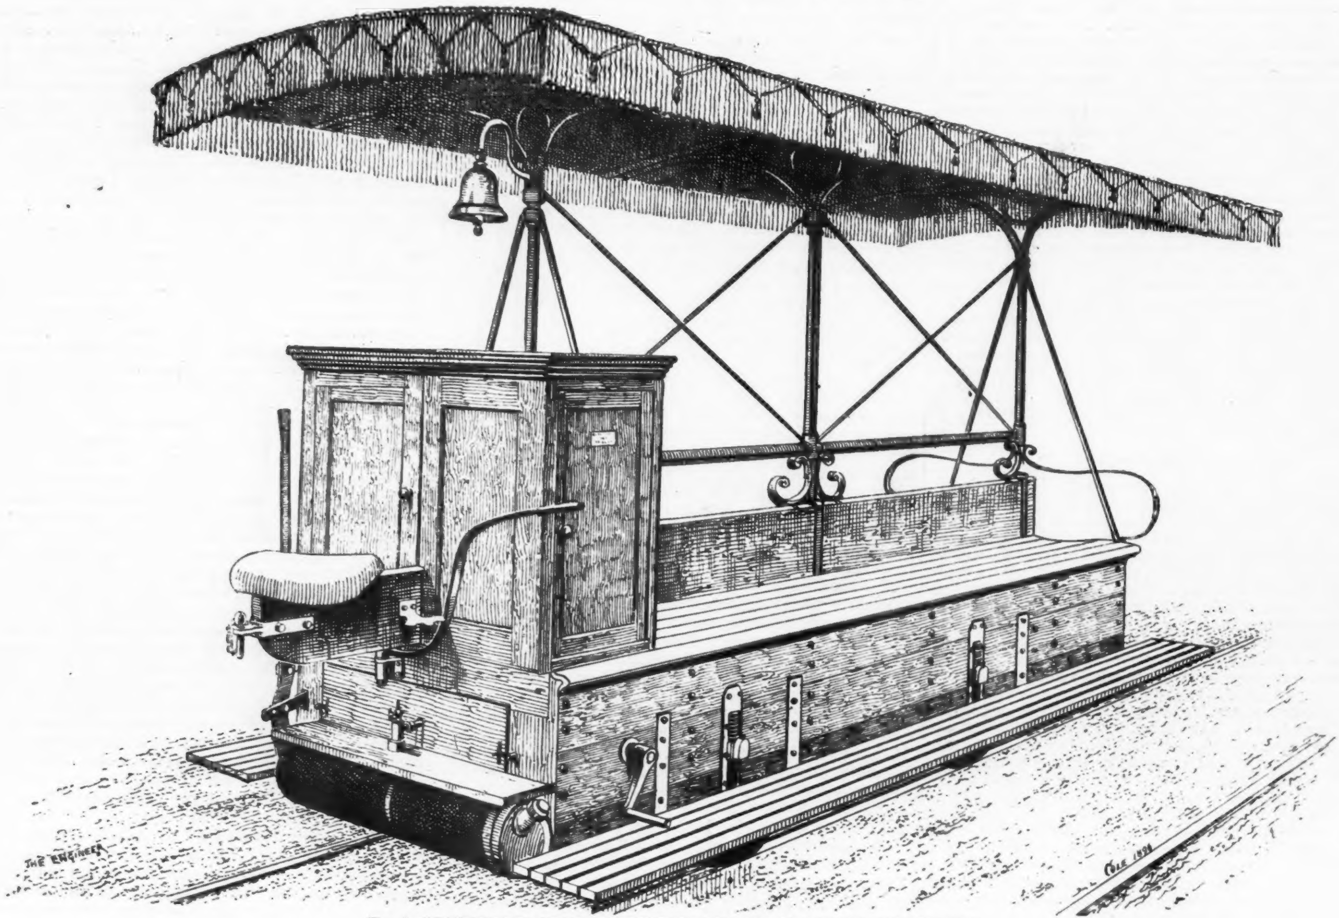

Fig. 1—PERSPECTIVE VIEW OF SELF-PROPELLED CAR FROM MOTOR END

HORSELESS CARRIAGES.

AMONG the vehicles exhibited in the Imperial Institute Exhibition is a narrow-gauge tramcar for carrying about a dozen passengers on longitudinal seats, as shown in the accompanying engravings. It has a light canopy over it, and is propelled by a Daimler motor placed in the case shown at one end. At the same end is the seat for a driver, within whose reach are placed the two levers necessary for controlling the movements of the car, the arrangement of the motor, the gearing, and the brake and gear levers. The motor we have already described* as to its oil or benzoline, and air-supply arrangements. It has two cylinders, and is connected to the driving axle by strong gearing thrown in or out of gear by a flat bar connected to the brake-lever M. On this bar is a projection having an inclined surface. This passes through a slotted head projecting from the end of the hollow continuation of the crank shaft at K, the head being connected to the friction clutch by a rod through the hole in the shaft up to the clutch at L. Thus when the lever M is pulled to put the brake on the driving wheels, the driving power is simultaneously cut out by the separation of the friction clutch surfaces, the which are pressed together by a spiral spring which is seen between the outer bearing and the small pinion E. When the latter is in gear, as shown with the wheel G on the intermediate shaft, the slowest speed is made, and by pulling the lever N out, the pinion F is put into gear with the wheel H, a higher speed being obtained. From the third wheel on this shaft the wheel I is driven. At D D are the two cylindrical exhaust boxes. The exhaust from both cylinders passes into the box nearest the engine, and from this it passes by a pipe to the bottom of the second box, from the top of which it passes into the air by a pipe which turns over from the top and leads it to near the ground. The oil vessel is not shown in our sketch, but provision is made for about a day's working. The arrangement of the car and its motor is very neat, and it gives a good idea of what may be done for vehicles for light narrow-gauge tramways or tramroads.

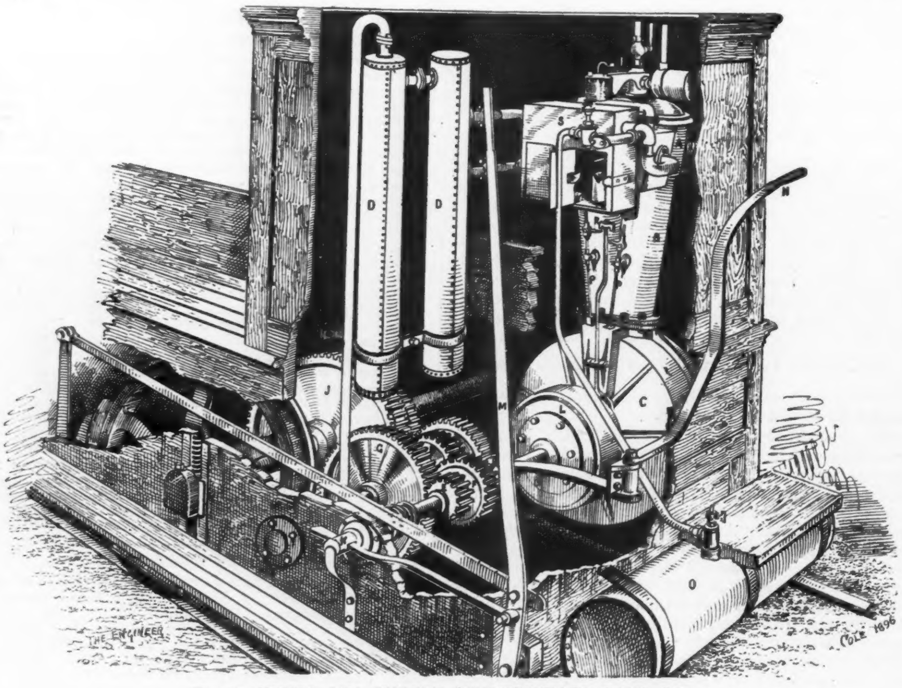

Fig. 2—MOTOR AND GEARING—SELF-PROPELLED TRAM CAR

---

* THE ENGINEER, December 20th, 1895.

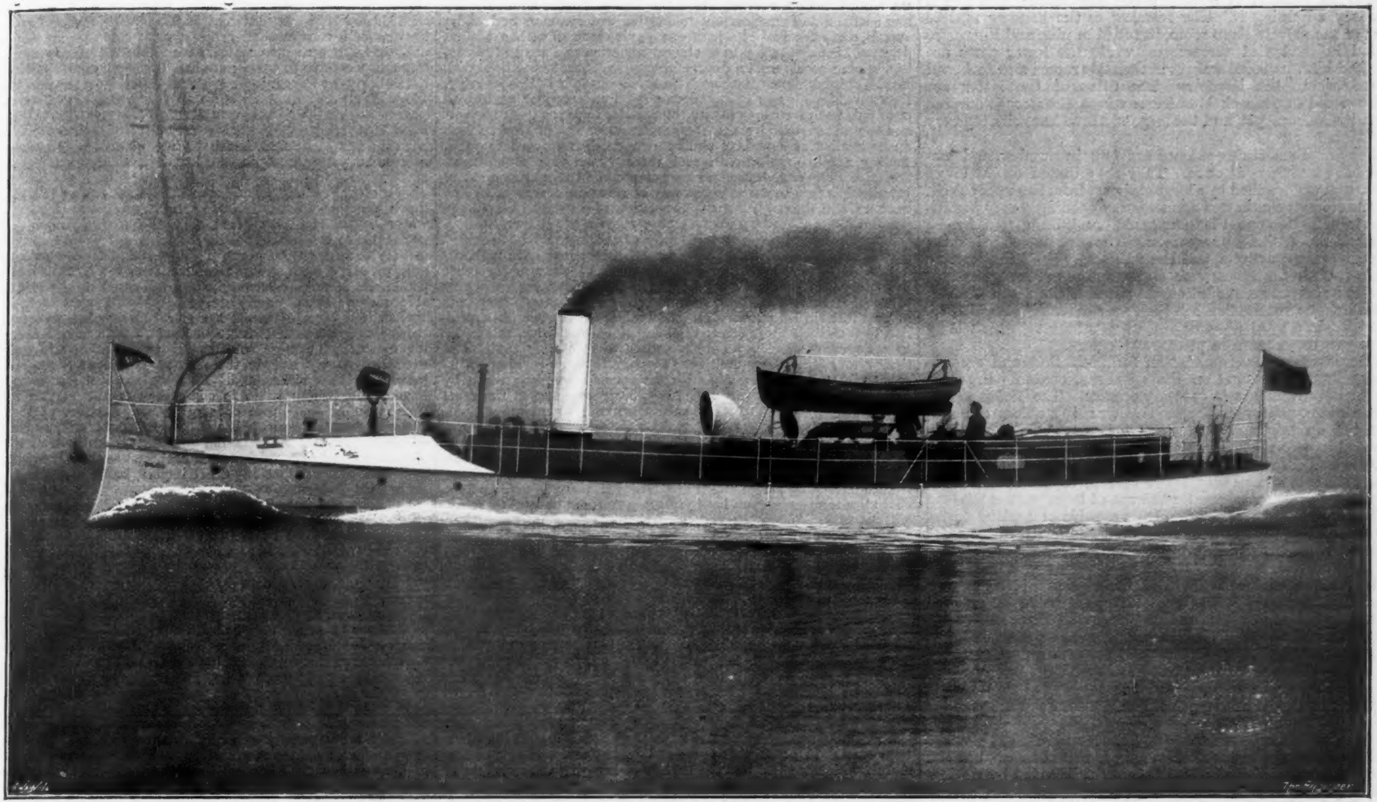
RHEA FIBRE.

THE great strength, length, and lustre of the fibre of the rhea plant so eminently adapt it for use in the textile manufactures, that its production in quantity in an economical manner and of suitable quality constitutes one of the most important problems of the day. The history of the many endeavours to effect this object extends back some forty years and more, and many thousands of pounds have been expended in the endeavour to compass the end in view. The solution of the question has been sought mainly in two directions—the mechanical and the chemical. At first, and for a long time, attention was chiefly directed to mechanical means, and the Indian Government has thrice within the last five-and-twenty years offered a handsome reward for a machine which should produce the fibre in a condition suitable for the required purpose. The French Government also took up the matter in 1888, and offered prizes for any process or machine by which the fibre could be produced in commercial quantities and of proper quality. The fibre occurs in the stem of the rheea plant, being embedded in a resinous substance, which in its turn is enclosed within the bark, and the greatest difficulty in the way of success is the satisfactory treatment of the gumming matter. Hence chemical science stepped in to aid in the solution of the problem, M. Frémy, the celebrated French chemist, being among the first, if not the first, to devise a method of chemical treatment, which was brought before the public in 1883. Since then several methods have been proposed, but none appear to have been applied commercially, at any rate not in this country. A recent invention in this direction is that of Mr. Henry Ferguson, who, after several years of experiments and research, perfected a system which has been put in practice on a commercial scale at the Phœnix Spinning Mills, Brighouse, Yorkshire. The process is both simple and effective, and at the same time economical. The stripped bark containing the fibre, and known as "brown barked rheea" is packed in large openwork wire cages, which hold the bark in separate layers, thus preventing them becoming matted or entangled. When charged, the cages are immersed in a solution of caustic soda for about three hours, the solution being maintained at the boiling point by steam heat. By this means the extraneous matters, consisting of bark and the gum in which the fibres are embedded, become softened, and the cages containing the fibre are then transferred to a tank of warm water, in which they are kept at a given temperature for several hours, the result being that the fibre is automatically de-barked in a stationary position, the use of scutching machinery being obviated. On removal from the warm bath the fibre is well washed in cold water, and is then found to be thoroughly prepared for the use of the spinner, so far as relates to the complete removal of extraneous matters. In order, however, to adapt it for use on existing machines, and to impart suppleness to it, the fibre is immersed for a short time in a cold composition of vegetable oils, alkalies, and water. On removal from this oleaginous bath, the fibre is air dried, which completes the process of preparation for spinning. The prepared fibre is taken to the spinning mill, where it is made into sliver, which is spun into yarn. It easily spins to all counts, and according to an expert in rheea treatment of thirty years' standing—Mr. Taylor Burrows—Mr. Ferguson can be said to have definitely solved the problem of producing rheea fibre in a cheap and effective manner, the fibre resulting from his treatment being fine and uninjured. Mr. Burrows expresses the opinion that "there is now every certainty of this beautiful fibre becoming one of the most important of textile industries."

THE Wolverhampton Corporation is applying for various powers for the purpose of establishing new waterworks, in addition to those at present existing. Borings have been made, and the estimated cost of sinking the wells, putting down the plant, &c., is £35,000.

THE STEAM YACHT SCUD

MR. J. S. WHITE, COWES, BUILDER AND ENGINEER



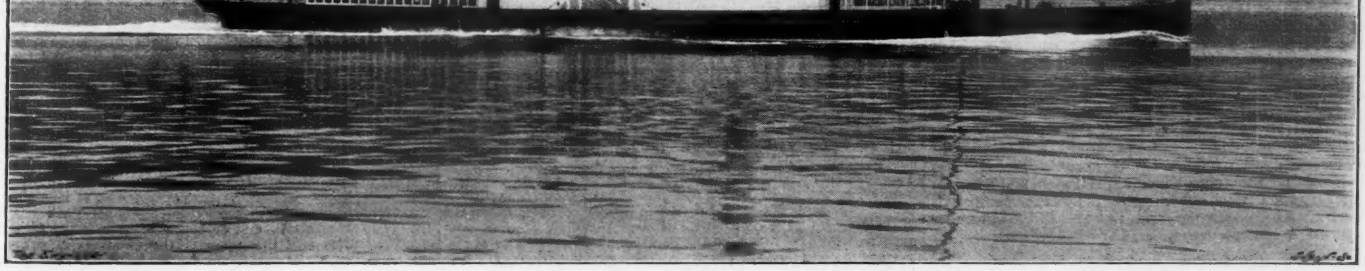
STEAM YACHT SCUD.

THE Scud is a steel screw "turnabout" yacht of the following dimensions:—Length over all, 90ft.; breadth, extreme, 10ft. 9in.; depth of hold, 5ft. 6in. She has been designed and built to the order of Mr. A. H. E. Wood, late owner of the Rona, by Mr. Jno. Samuel White, East Cowes, I.W. The vessel is fitted up throughout in a most luxurious manner, having a moderate sized saloon aft, entered from a spacious cockpit, with owner's room, pantry, and w.c. adjacent. These apartments are enclosed by a mushroom teak deck-house having low-pitched skylights on top. The saloon is upholstered in the style of a first-class railway carriage, with silk curtains and edgings; and the panels are of selected pieces of pollard oak. The forward part of the vessel has been devoted to the crew's quarters, and is fitted up with pine lockers and folding cots. An electric light installation has been supplied throughout the vessel, with a projector forward. The steam steering engine, by the builder, is placed in the after peak, and actuates a quadrant on the forward rudder—this vessel having two being built on Mr. White's patent "turnabout" system. Our illustration gives a very good idea of the general appearance of the yacht. On her official trial trip at Stokes Bay she attained a mean speed of $20\frac{1}{3}$ knots, running smoothly and with a total absence of vibration.

The engines are of the compound surface-condensing type having one high-pressure cylinder, 11in. diameter, and two low-pressure cylinders, $17\frac{1}{2}$in. diameter, by 11in. stroke, working on three cranks set at 120 deg. The high-pressure cylinder is placed in the centre, and is fitted with a piston valve; the two low-pressure cylinders are fitted with flat valves. The air pump is worked by levers off the forward engine, and the feed pumps at a reduced speed through worm gearing at the forward end of the shaft. The shafting is hollow, and all the reciprocating parts are as light as possible and balanced. The main bearing and crank-pin brasses are of a special mixture of aluminium, the hotwell is fitted with a feed-filter, and there are also a feed-heater, duplex donkey pump, centrifugal circulating pump, Parsons' turbine dynamo, fan engine, and reserve feed tank in the engine room. The boiler is of the Blechynden type with incurved tubes, and so constructed to admit of every tube being examined and withdrawn individually without disturbing any other tubes. The working pressure is 200 lb. per square inch. The propeller is of Stones' bronze, 4ft. 10in. diameter, by 5ft. 3in. pitch, the slip at full speed being 9·7 per cent. The energy developed was about 550-horse power, the revolutions being 430 per minute. The machinery was specially designed to reduce vibration to a minimum, and proved singularly successful, the vibration at full speed being practically nil.

THAMES PADDLE STEAMER SOUTHEND BELLE

MESSRS. DENNY AND SONS, DUMBARTON, BUILDERS AND ENGINEERS



THE THAMES PADDLE STEAMER SOUTHEND BELLE.

UNTIL within quite recent years the steamers employed in passenger service on the Thames were, both as regards their speed and accommodation, very much behind the capabilities of modern naval science, and they presented a poor appearance in contrast with those which had long been running on the Clyde. That a city with a population of between four and five millions of people, and situated upon a river possessing the attractions of the Thames, should be served with so antiquated and uncomfortable a class of steamboats was a puzzle to visitors from the North and elsewhere, more especially in view of the well-known proclivities of the Londoners for tripping and holiday making. This state of things could not always continue, and so, thanks to the enterprise of such companies as the Belle Steamers Company, an end has been put to it. There is now to be found on the Thames a rapidly increasing fleet of pleasure steamers second to none found elsewhere in the United Kingdom, or, indeed, in the world. One of the most recent additions to the Thames passenger fleet is the Southend Belle, recently built and engined by Messrs. Denny, of Dumbarton. Our illustrations show the engines of this vessel, as well as her appearance when running her steam trials on the Clyde.

The Southend Belle is a saloon steamer with a long promenade deck, her principal dimensions being 249ft. by 30ft. by $10\frac{1}{2}$ft., and she has accommodation for about 2000 passengers. The first-class passengers' saloon is at the after part of the upper deck, and it is fitted up in the most artistic and luxurious manner. The sofas are arranged in horseshoe shaped bays, and both sides of the apartment are fully occupied with large plate-glass windows, divided by decorated pilasters, and hung with blue and gold silk tapestry curtains. The sofas are upholstered in blue frieze velvet, and the floor is covered with Brussels carpet, overlaid down the centre passage with a broad runner of thick velvet pile. Additional light is admitted by handsome skylights, which add greatly to the appearance of the apartment. Just on the fore side of the first-class saloon are the ladies' boudoir and two private cabins, while forward of these are the vestibule and stairway to the lower or dining saloons. The ladies' boudoir is a very pretty apartment, and has a lavatory adjoining it. The framing of the boudoir is, like that of the private state room, panelled in pine and lincrusta, tinted in shades of terra-cotta, while the lower parts are finished with polished walnut in the state rooms and darkened mahogany in the boudoir. The sofas of the latter are upholstered in peacock blue frieze velvet, the floor is covered with Brussels carpet, and the large windows have silk tapestry curtains.

The first-class dining saloons are two in number, and can seat 120 passengers at once. They are situated on the lower deck, and are reached by a large stairway from the upper deck. In the framework around the stairway opening a very beautiful stained glass panel is introduced, containing four heads, symbolical of the four seasons. The decoration of these saloons is most artistic, and the upholstery is all that can be desired, both for appearance and comfort. Throughout all the first-class accommodation the metal fittings are electroplated. The ventilation has been very carefully attended to, resulting in a total absence of that "stuffiness" which is by no means uncommon in pleasure steamers.

The lavatory accommodation for both first and second-class, situated as usual on the sponsons, contains the most recent improvements in sanitary science. The ticket office, parcel room, pantry, larder, and other ship's offices are also situated on the sponsons. The fore part of the vessel is devoted to second-class passengers, and the berthing of the officers and crew. Immediately on the fore side of the boiler-room there is a large airy lower saloon, especially intended as a private dining saloon for the use of large parties wishing to have it reserved for them. It is capable of seating forty-six persons, and is in direct communication with the forward pantry, which contains every convenience for prompt and efficient service.

Without going into a detailed description of the accommodation provided for second-class passengers, it may be sufficient to state that it is second class only in name.

On the promenade deck, situated in a large deck-house, is an extensive bar in the American style, also a special cabin similar to those on the deck below, stalls for the sale of newspapers, confectionery, &c., and the captain's cabin. This promenade deck is of exceptional area, and provides space for nearly 400 persons.

Our illustration shows that the Southend Belle has a smart and powerful appearance. Not only is this the case, but she is as trustworthy as she looks, being subdivided by no less than eight water-tight bulkheads, and constructed to satisfy the Board of Trade requirements both in regard to strength and life-saving appliances. She is fitted with both bow and stern rudders for the greater facility of steering in a crowded waterway; has an excellent installation of electric lighting, and is steered by the steam gear of Messrs. Bow and McLachlan.

A by no means unimportant point in connection with passenger comfort is the means adopted in the Southend Belle for arresting the small cinders, sparks, &c., which proceed from the funnels of steamers, especially when forced draught is employed. A continual shower of hot cinders and dust is a source of great annoyance to all, especially lady passengers, and to cope with it Messrs. Denny and Brace's patent spark catchers have been fitted, an apparatus which in this and other cases is always a complete specific against the nuisance.

The Southend Belle is fitted with direct-acting triple-expansion diagonal paddle engines, illustrated on page 592, having cylinders 28in., 41½in., and 60in., with a length of stroke of 5ft. The valve gear is upon the fixed quadrant principle, as designed by Mr. W. Brock, the valves being on the top of the cylinders, thereby reducing the athwartship space occupied, and bringing the gearing within convenient reach of the engineer. Piston valves are fitted to the high-pressure and intermediate cylinders, and a flat slide valve with balance rings to the low-pressure. The entablatures of the engines are of cast steel, and stayed at top with a cast steel tube carrying the valve motion quadrants, which are also of cast steel. The centrifugal circulating pumps are by Messrs. Drysdale, of Glasgow. The air pump is worked off the main engine, as also are the sanitary and bilge pumps. The air pump discharges the water into a tank from which it is pumped to the boilers by a pair of Weir's direct-acting pumping engines, each of which is sufficient to feed the boilers when the vessel is developing full power. One of Edmiston's feed filters is fitted on the main feed-pipe range, and is found to act very efficiently in preventing the passage of grease or oil from the engines to the boilers. It may also be noted that in the main lubrication of the engines oil is not used, there being fitted a complete installation of the Axiom automatic lubricating gear, which is also found to be both efficient and economical, besides keeping the engine-room clean and free from the unpleasant smell of heated oil.

Steam is supplied to the engines from two boilers of the Navy type, having in all six furnaces, and working at a pressure of 160 lb. per square inch. They are worked upon the closed stokehold principle, and air is supplied to them by a large fan driven by a Chandler silent enclosed engine, which, along with the steering gear, stands upon the deck over the boilers. The joints to the pipes exposed to high pressure are made by means of Pope's patent flanges, and the main steam pipes are hooped with steel bands on Mr. Peter Denny's system, to strengthen them against the risk of bursting.

Upon her trial runs on the Clyde the Southend Belle attained a mean speed of 21¼ miles per hour. She is intended for the further development of the company's passenger service to Southend, Clacton, Felixstowe, Harwich, and Ipswich. Her construction was superintended by the company's engineer, Mr. Dugald Brown, and she was fitted out under the supervision of her commander, Captain Holland.

SHIPBUILDING IN GERMANY.*

By C. FERD. LAEISZ, Associate

ASSUMING that a brief survey of the development of the shipbuilding industry in the country you are about to visit may, although totally devoid of scientific value, be not altogether unwelcome in the present stage of your proceedings, I venture to lay before you the following remarks. In the old times of wooden sailing vessels shipbuilding in this country had attained to a considerable degree of excellence, and many a fine clipper ship has been launched from German yards, both in the Baltic and at North Sea ports. Since, however, wood was superseded by iron, and an ever-increasing portion of the world's carrying trade fell to the share of steamers, the natural resources Great Britian possesses in her enormous mineral wealth close to the sea, allied to her great capital power and wonderful enterprise, have assured her an ascendancy in this as in many other industries, with which other countries have found it extremely difficult to keep pace. It is thus we lagged behind very considerably, and not until Great Britain had accumulated an enormous tonnage of iron steamers and sailing vessels, were the first efforts of our yards crowned with a certain degree of success. They have always laboured, and are still labouring, under considerable disadvantages in the competition with British shipbuilders. Although labour is cheaper in this country, that advantage is more than outweighed by the higher cost of all material, and of coal, owing to the greater distance from the pits and the mines, and by the comparative scarcity of work, which does not allow of squads of skilled men going from yard to yard, finding ample employment, and thereby working much more actively. The restrictions our laws impose on the employment of juvenile labour also stand in the way of creating a race of skilled workers, and the contributions to accidents-insurance and old-age pension funds obligatory upon employers are a heavy burden.

Since, however, the growing trade of the country has enabled our shipowners to materially increase their tonnage, and particularly since the Imperial Admiralty has given constant employment to a number of yards, thereby largely fostering the inventive genius of naval architects and marine engineers, and educating thousands of men into skilled workers, our shipbuilders have been in a position to turn their attention to the highest class of work, and aspire to a degree of efficiency enabling them to rank with the best of their profession. The quantity of tonnage they are turning out is, of course, small as compared with the enormous figures shown by British statistics; in point of quality, however, some of the craft "made in Germany" may be well worthy of your notice.

I cannot here dwell on the various stages of Admiralty work, which I have to leave to someone more competent to speak upon, but confine myself to specimens of our merchant navy. In its development we have, naturally, mostly followed in the wake of British enterprise; here and there, however, you will find we have shot ahead, although you have not often suffered us long to retain a front seat. When the ocean greyhounds came into fashion in the North American trade, the North German Lloyd were among the first to put a number of high-speed vessels on that line, and they have for a considerable time had more steamers of that class running than all the other lines put together. The first half-dozen were built at Fairfield, the later editions at the Vulcan Yard, of Stettin, where a steamer is just now building for the same owners, which is to vie with the famous Cunard flyers. Her dimensions are 625ft. between perpendiculars, 66ft. beam, and 43ft. moulded depth; while her twin engines are to develope 28,000-horse power. The same company have another boat of similar properties building at Dantzic by Mr. Schichau, the well-known torpedo-boat builder, who has also supplied a couple of mail steamers for their Eastern service.

The Hamburg American line were among the first to introduce twin screws in ocean steamers; and one of them, the Fürst Bismarck, which has just had the honour of bringing the members of this Institution over from England, has, I trust, merited your approval as a fair specimen of German shipbuilding and engineering skill. She and another of her type were built by the Vulcan Yard above mentioned, while two sister ships were supplied, one by Messrs. Laird Brothers, and the other by the Fairfield Yard. The same owners have also taken to twin screws in their large cargo boats, some of which were built by the Vulcan Yard and by Messrs. Blohm and Voss, of Hamburg, and they have at present a huge steamer of that description building by Messrs. Harland and Wolff, which is destined for some time, and until you go one better, to rank as the biggest carrier; her deadweight capacity being over 12,000 tons. Her dimensions are 560ft. by 62ft. by 41ft. You will have occasion to inspect the yard I have just referred to—of Messrs. Blohm and Voss in this city—and I think you will find it admirably situated and well laid out and fitted with all the machinery required to produce excellent work. At the same yard you will find in course of construction a floating dry dock capable of lifting 17,000 tons, of which we are sorely in need, considering the great displacement of many of our new ships. At another yard close by, the Reiherstieg, you will find an off-shore dock, in which vessels are hauled in sideways, as there is not sufficient space to put them in end on. At each of these two yards there is a passenger steamer building for the East African Mail service; the first of them is to sail on July 10th, on an excursion round the Dark Continent, and I hope some of you will be disposed to take passage in her.

Turning again to cargo boats, I may mention that the first steamers carrying oil in bulk were built for German owners by Messrs. Sir W. G. Armstrong, Mitchell, and Co., who have supplied quite a fleet to the German American Petroleum Company and other owners. Latterly, however, some boats of this class were also built in German yards. The chance is that, in going over our yards, you will see one or two tankers repairing, as the strain upon their numerous bulkheads has proved the delight of the shipbuilder who has not built them. I must say, however, that in this respect, as in every other, each succeeding production shows that the difficulties attending this description of vessel are being better contended with. Our attention has also been turned to the turret-decked ship, and there is now at Flensburg a so-called elliptical steamer building, which is expected to be an improvement upon the Sunderland type. The ordinary plain cargo steamer, the ocean tramp, is a species that has prospered but very indifferently in this country, where I think she cannot be worked as economically as in England. Over and over again owners who began with tramp steamers have ended by finding them employment in some regular line, or they have been swallowed by the lines. It is probably due to this fact that our steamers show a coefficient of fineness seldom over 0·76, and I know of scarcely a German steamer with as full lines, as there are many under the British flag, approaching, or even exceeding, 0·8.

All improvements in the engine department have, of course, been closely followed in this country, and we have endeavoured to profit at not too great a cost by the never-resting inventive genius of the marine engineer. The Kosmos Line, of Hamburg, for instance, were among the first who adopted quadruple expansion engines of Messrs. Wigham, Richardson, and Co.'s pattern; and since hydraulic riveting permits of subjecting boilers to very high pressure with absolute safety, several of our engine works have turned out quadruple engines that have given the utmost satisfaction. You are, of course, familiar with the plan devised by our colleague, Mr. Schlick, of balancing engines, so as to materially diminish vibration. The paper he read upon the subject before this Institution two years ago has met with much approval, and his name, allied to that of some eminent English engineers, has gained the Yarrow, Schlick, and Tweedy System marked success in your country, as well as in France and Germany. Forced draught, on the other hand, is not much believed in in this country, and some of its devotees have been cured of their partiality at their own expense. Perhaps ill-luck in the beginning has deprived us of the courage to go in for the right system, and give it a thoroughly fair trial.

Sailing shipowners in this country have long clung to wood, and their reluctance to go in for iron was not overcome until builders proved capable of turning out iron vessels that were as fast sailers as our old wooden clippers, and yet required very little ballast. In the last twenty years, however, a number of very fine iron and steel sailing ships have been built in German yards, and some of them have become famous for their record passages. I may name the Preussen steel ship, built by Blohm and Voss, Iquique to Hamburg, 71 days; Luna, iron barque, built by the Germania Yard, Rangoon to Falmouth, 92 days; Placilla, steel four-masted barque, built by Tecklenborg, Channel to Valparaiso, 58 days; Selene, steel ship, built by the Rostock Yard, Channel to Melbourne, 71 days; Hebe, steel four-masted barque, built by Blohm and Voss, Channel to Adelaide, 69 days. The last-named vessel covered 13,485 nautical miles at an average speed of 8·14 miles per hour, and the Selene averaged 9¼ knots over a course of 6425 miles. Mr. John C. Tecklenborg, of Geestemünde, built last year a steel five-masted barque, the Potosi, which is at present the largest sailing vessel afloat. Her dimensions are 360ft. between perpendiculars, 49½ft. beam, 31ft. moulded depth, and 4026 register tons; she carries 6200 tons deadweight, displaces 8470 tons on 25ft. draught, and spreads canvas of 50,020 square feet sail area. She has proved a very fast sailer, and a most comfortable ship at sea, and she tacks with the greatest ease. The very heavy strain these large vessels have to undergo when heavily laden has shown the advisability of strengthening them beyond the requirements of Lloyd's rules; bulkheads close to every full-rigged mast have proved an excellent transverse strengthening, and a bridge-house amidships for about one-sixth of the vessel's length not only largely adds to her structural strength, but gives her a considerable reserve buoyancy, and prevents her decks being swamped fore and aft.

Few of our sailing vessels are fitted with water ballast, not so much, perhaps, from technical as from economical reasons; where water ballast has been fitted deep tanks have proved decidedly preferable to the double bottom, which is apt to raise the centre of gravity to a dangerous point, if the vessel is loaded with a homogeneous cargo, such as coal, rice, &c. Very few German owners had confidence in composite vessels, and the number of them built in this country is consequently exceedingly small; fortunately so, I may say, as that type of vessel has soon become obsolete. Steel was readily adopted when it first appeared on the scene as a shipbuilding material, the more so as it was produced in this country in excellent quality, and, in the first few years, at a comparatively lower price than in England. Latterly, however, our steel makers have found it impossible to compete with the British material, which can be laid down cheaper at any German port than the home-made article which has to pay railway carriage over a long distance. It must be borne in mind that no duties are imposed on any shipbuilding material, nor on coal, just as there is no difference in the harbour dues, or any other impost, between a German and a foreign ship.

I should like here to correct an error I have frequently met with in English papers, that is the belief that our merchant navy is largely subsidised by the Government. Such a contention can hardly be sustained, if you consider that, with the exception of two mail subsidies—one of £200,000 yearly for the Eastern and Australian service, another of £44,000 for an East African line—there are no subventions, premia, surtaxes, or privileges, of any shape or form, in favour of ships built or owned in this country over those of other nationalities. Legislation, which is doing so much in certain countries to hamper enterprise, has not quite spared us, but it has, so far, been satisfied to let shipowners look after themselves, provided they do everything that can be desired to render navigation as safe as possible, and indemnify sailors who have come to grief through accidents at sea, and their widows and children. A Mutual Accident Insurance Association, to contribute to which is compulsory on every German shipowner, has to assess the pensions fixed by law, and to levy the yearly contributions; and, as it has thus become the joint interest of shipowners to prevent accidents, the Association is empowered to enforce whatever it deems imperative for the safety of life and limb on board ship. Its regulations embody, therefore, a great many things provided for by the English Life-saving Appliances and other Acts, and its surveyors, guided by the advice of the Germanic Lloyd, are fulfilling the duties incumbent upon the Board of Trade officials in your country. We have not yet seen the wisdom of imitating the English Load Line Act, but we have our Bulkhead Committee pondering on the solution of the problem of rendering our ships unsinkable, and thus satisfying the clamour of the landsman, who is loath to acknowledge the truth of the old adage, *Navigare necesse est, vivere non est necesse.*

MUNICIPAL ELECTRICAL ASSOCIATION.

THE first annual convention of this recently formed body was opened at 10.15 a.m., Wednesday, 10th June, by Mr. Arthur Wright, the borough electrical engineer of Brighton, in the Lecture Theatre of the United Service Institution, Whitehall. Without any preliminaries he immediately proceeded to deliver his address, which we publish below.

The attendance was very good, and besides the municipal electrical engineers themselves, there was a good sprinkling of other persons interested in the work of the convention. The Board of Trade was represented by Sir Courtenay Boyle, and later on by Major Cardew, while a number of the chairmen of Municipal Electric Lighting Committees were also present.

PRESIDENT'S ADDRESS

You have done me the great honour of asking me to preside a this our first annual convention, and I feel I cannot take up a portion of your time to better purpose than by proving the pressing want of some such Association as we are now inaugurating, to further and protect the interests of the municipal electricity undertakings, which in the very near future will probably exceed eighty in number, and represent a capital outlay amounting to £4,000,000 sterling. I, therefore, propose to show how exceedingly numerous are the questions that are being constantly met with in our special branch of electrical engineering, and why, in my opinion, none of the existing societies can really supply our want.

I think you will share my regret that the very nature of our problems, and the particular standport from which we municipal men have to look at them, prevents us from deriving the great benefit of having among our regular members the numerous experienced managers and engineers of companies supplying electricity.

Although the objects of this Association are generally and very tersely stated in the constitution, I may be allowed to amplify the wording there by stating that, in promoting the special interests of municipal electricity undertakings by bringing together, for the purpose of comparing experiences, the men responsible for their management, we hope to succeed in getting the representatives of the ratepayers to participate in our discussions, and to obtain their valuable co-operation and municipal experience in trying to solve our difficulties, so that our recorded conclusions may receive the greater consideration from the head governing bodies. For the purpose of classification, I will divide some of the problems that have already confronted the management of municipal electrical undertakings into three distinct groups—those relating to policy, to commercial, and to technical questions. Although it could be truly said that some of the questions of policy come within the sphere of one, if not more, of the older societies, and that many of our commercial and technical problems could be advantageously discussed from a general point of view before some of them, yet it must surely be to the advantage of the community to have the particular interests of our industry safeguarded and properly represented by an Association comprising among its members the representatives of the ratepayers and the technical officers in charge.

The group of "Questions of policy" must obviously include those relating to what should be the proper period allowed for the repayment of loans. That some decision ought soon to be arrived at is evident when we remember that in London the vestries can get permission from the County Council to repay their capital in periods exceeding forty years, whereas, in many of the provincial towns, twenty-five years is the period fixed by the Local Government Board. There is obviously no reason why posterity outside the metropolis should be so much more generously dealt with, at the expense of the present generation, or why folks in the provinces, who have to pay all the expenses and suffer from the inevitable troubles incidental to the starting of a new industry, should also have to behave so much more handsomely to people who it must be remembered will have an advantage over us in being born twenty-five years later in the world's progress.

---

* Read at the summer meeting of the thirty-seventh session of the Institution of Naval Architects, June 9th.

Take, again, the question of assessment of electricity works and mains. The interpretation of the law on this point is so uncertain among experts that it is actually possible, in the case of two municipal electrical undertakings in the South of England, for the relative assessments to be nearly as ten is to one, although the capital invested is about equal. At first sight, to anyone not directly interested in the success of municipal electricity works, this variation of assessment would probably not be considered very serious, as apparently it is only a question of taking money out of one municipal pocket and putting it into the other; but to the men responsible for the success of this one special department, the question of assessment affects the vital results of the electricity undertaking paying or the reverse, and increases or diminishes the near possibility of a reduction in the tariff for supply, which they realise is necessary to ensure the general use of electricity among all classes of ratepayers.

The decision arrived at, as to what policy should be pursued in relation to the profits obtained, has a similar effect on the rapid growth of municipal electricity undertakings. The practice of insisting on maintaining high tariffs, so as to be able to hand over large profits to the general body of rateyayers, on the ground that they should be handsomely repaid for their risk in mortgaging their rates, is very naturally resented by those ratepayers who make use of their own municipal supply. They contend that by this policy they are being severely taxed, in the shape of having to pay heavy electricity bills, for the benefit of a number of people who we now know ran practically no risk at all, and as non-users do not help their own municipal enterprise. Again, when we remember how prone some municipalities are to pride themselves on the large profits made in their undertakings, and when we remember the policies advocated by some of our friends, who would lead us to imagine that the object is simply to supply electricity to those who can afford to pay the necessarily high initial price, it is evident that good must come from our discussing this point, and bringing home to the governing bodies the truth that the criterion of success of a municipal electricity undertaking, trading in what cannot be called a necessity, is not so much the profits made out of the undertaking as the more or less general use the ratepayers make of the supply offered.

Those who advocate putting aside a large proportion of the annual profits to building up a reserve fund for use in case of unlooked-for contingencies are often charged with want of consideration for the general ratepayers who backed the necessary cheque in starting the undertaking; these critics, however, forget that in this matter it is the duty of a Corporation not only to start, but to continue to supply a cheap and satisfactory service, and to insure against any possible mishaps that may arise in the future. Again, the question of creating a mutual electricity works insurance fund seems a fitting subject for discussion, considering how all our works are now being tarred with the same brush by the fire offices, and classed by them among the same hazardous risks as factories, &c. Again, the practice of the various municipalities differs considerably in deciding whether one or separate committees should manage the gas and the electricity departments. The former practice frequently prevails, and what seems to many of us the inevitably slow progress that results from such a policy is not at present fully realised. In some towns human nature seems to be so over-rated that their Corporations have made one manager responsible for these two competitive departments.

Another point in connection with the general policy that is to be followed in carrying out municipal electricity undertakings is one on which electricity works managers are not by any means all agreed among themselves—namely, whether a Corporation should make all ratepayers pay a uniform profit on the cost of production of the electricity they individually consume, or charge a uniform price to everybody. I scarcely need add that the two systems cannot both be adopted. The former has the advantage of justice on its side, while the latter has that of greater simplicity; unfortunately, however, it involves the commercially unsound principle of charging the same price for commodities which may individually require capital outlays differing as much as tenfold or more.

Again, owing doubtless to the youth of our industry, no definite rule has yet been established among municipalities as to how they should charge for electricity consumed in their street lighting and public buildings; whether, for instance, this should be done on the sound principle of having only one universal tariff, or should special tariffs be arranged for their own municipal consumption. The latter course, in view of the charges that are constantly being made of some Corporations making their electricity profits out of their own pockets, seems difficult to justify. The wisdom, or the contrary, of municipalities taking joint action in threatened patent litigation, or in view of new Parliamentary regulations or restrictions, wants discussion and settlement. The questions whether municipalities should carry out the wiring of private premises in competition with local tradesmen; whether they should have powers to hire out motors, arc lamps, and fittings; the advisability of establishing municipal telephone systems, electric fire alarms, and electric fire engines; the possible benefits of combining the water and electricity works; the use of the plant in periods of light load for the production of such by-products as disinfecting fluids, acetylene and carborundum, &c., are all interesting problems of policy, which I trust will be ventilated and argued at our conventions.

Another municipal variation of practice is shown by some believing that it is to the interest of the ratepayers to employ a sufficiently strong resident engineer to carry out both the design and the running of their undertaking, on the ground that no one but a resident can properly grasp and retain the local bearings of the problems involved in a distribution scheme of the nature of electricity supply, while others consider that a consulting engineer, owing to his having the opportunity of gaining much more varied experiences from all sorts and conditions of towns, should serve them in better stead. On the answer to the above delicate question of course depends what should be considered the proper remuneration of the resident engineers who have the virtual control, whether their councils fully realise it or not, of property amounting in many cases to hundreds of thousands of pounds.

The touring experiences of many of our best electrical engineers is advantageous to the men themselves in gaining fresh experiences, but it increases the unfortunate loss to the Corporations when the engineers are snapped up for better appointments elsewhere. The existence of this constant system of changing proves beyond all doubt that many Corporations have not yet realised the value of the immense experience these men take away with them, and how impossible it is to replace their experience by even better men until some considerable time has elapsed. Some Corporations fully see the advisability of getting their engineers to visit other electricity works for the purpose of keeping up to date. The great extent to which the ratepayers benefit by this policy is not, I am sorry to say, apparent to all the governing bodies. Although many of our senior brother municipal officers will be prone to think that some of the above questions do not come at all within our province for discussion, I feel that if we obtain the valuable assistance of the chairmen of our committees in discussing and solving them, there will be little difficulty in getting the correct principles accepted and adopted by our councillors.

All the above, and a host besides, are questions of policy that press for solution, and I think many will agree with me in thinking that if we leave them to the other societies to fight out, we may as well adopt the equally slow course of leaving each Corporation to worry for themselves when they are individually confronted with them. The founders of this Association saw that co-operation in arriving at conclusions upon these problems would save a great deal of time, and would avoid the repetition of a vast amount of work by the different Councils. They also saw the importance of putting in black and white the results of careful consideration by competent men of the different policies advocated, so as to afford help to those among their *confrères* who may be in need of it.

With the second class of problems connected with our work, viz., those requiring consideration from a commercial point of view, it seems to many of us quite impossible to get this class of question satisfactorily and adequately discussed before societies, however influential and well organised, which comprise among their members men representing absolutely conflicting interests; and it appears equally futile to discuss these questions before institutions including among the members the managers of electricity supply companies, whose object in developing their business, viz, to get the biggest return on the capital expended, is so entirely different to ours in trying to supply the greatest number of ratepayers at the smallest possible cost. Moreover, it can hardly be fair or interesting to the majority of the members of existing engineering institutions for us to take up their time discussing problems which can only properly be thrashed out before a special body representative of our particular subject of municipal electricity supply.

Under the heading of "Commercial problems" must come the important question of the proper organisation of the electrical staff; that is to say, how to so organise a staff, and separate the undertaking into separate departments, as to be able to define the duties and responsibilities of each member of it, and to insure against any discontinuity in the business in case of illness or resignation of the chief officers. Whether the principle of giving the staff a bonus depending on the results of the year's working is likely to be to the benefit of the ratepayers or not is a question on which much can be said on either side; and it ought not now to be difficult to decide what should be considered the proper scale of remuneration to the different members of the staff in accordance with their term of service, so as to avoid as much as possible the inconvenience and loss of experience to a Corporation of having their officers merely use the undertaking as a sort of training school.

I think a very useful purpose would be fulfilled by our Association if we could all agree on some proper method of keeping electricity accounts, or perhaps I ought to say, of properly filling in the Board of Trade regulation form of accounts. Everyone will now admit the great value electric lighting statistics, financial as well as technical, would be, providing they were made on an absolutely uniform basis, and I trust some of our members will early suggest some form which we can all approve and adhere to. The question as to the right method of determining the cost of electricity supply has yet to be thrashed out, as it seems to some of us that the usual method of taking the average cost of all the units delivered is as useless for the purpose of calculating the cost of supplying any one class of consumer as if a land agent were to calculate the cost of a particular plot of ground in a town by dividing the total land value of the town by its total area. On this matter of costs depends the very important question of the actual cost of electrically lighting streets; also whether there is any justification, commercial or otherwise, for the plan adopted in many towns of charging a lower rate for electricity consumed in motors than in lamps.

Another most interesting and still unsettled point is what should be the basis on which to calculate the cost of energy wasted in feeders, transformers, &c., for the purpose of determining the relative cost of different systems of distribution. I have not yet succeeded in meeting two men agreed as to how this should be done. Again, it has not yet been generally recognised, as some think it ought to be, that it pays a Corporation to cater in our industry for the same class of people that prove so remunerative to the railway companies, viz., those who choose to travel third class; and that it would probably be very much more advisable for Corporations to run mains into their districts, than only into the districts occupied by the houses of the rich and often absent residents, or the early-closing shopkeepers. To put it shortly, many of us have still to realise and prove to our governing bodies that it may be far better to get electricity used in a poor man's kitchen and one dwelling room than it does to get it into many of the drawing-rooms of the wealthy.

Again, you will all agree, I feel sure, that it is very important, in order to inspire confidence among the ratepayers, to show as early as possible after the starting of a municipal electricity undertaking that it can be made self-supporting, and therefore independent of the rates. With this object in view, it is an interesting problem in electricity supply to find whether capital is better employed in the early days of an undertaking in extending its sphere of operations into all parts of a borough, or in spending money on coal-saving refinements. To point out a danger confronting many of us, I may add that sound business men often express a belief that electricity undertakings would progress much faster if their managers took as much interest in understanding the commercial problems as they do in the over-absorbing engineering details and the fascinating scientific points connected with the industry.

The subject of wiring regulations and fire risks is one that has already received a great deal of attention, and I submit that it is still an unsettled question whether we are not weakening our position by enacting pages and pages of regulations which we have no very practical means of enforcing, and cannot afford to keep a sufficient number of inspectors to see carried out. Although I believe a certain amount of regulation writing is necessary in the early days of any industry, yet, in view of the utter absence of observed regulations concerning the use of paraffin lamps and compo gas pipes, one may be forgiven for thinking that it is better to realise at once the futility of electricity supply authorities formulating regulations—that the proper people to do this and see them carried out are the fire offices, and that the more thoroughly this is recognised the more likely these offices will be to fall into line and organise their staffs so as to ensure strict and general inspections. This seems to me to be the only way to improve the character of the interior wiring work, which at present varies much in quality.

With regard to the last group of questions, those of technical interest, which to most of us are infinitely more attractive than those of commercial expediency, it is hardly necessary for me to do more than enumerate many of the most pressing problems. Foremost among these, in my opinion, must surely stand the question of what should be considered the best system of distribution of electricity to any particular town or district. That the present state of things cannot be finality is obvious, when we bear in mind how numerous are the different methods at present advocated and in use for towns of comparatively the same class. Owing to the absence of some such Association as ours, this vital question has not yet been thrashed out by men who are unconnected financially with particular systems; but I hope we shall not be so very much longer now in settling upon some method of selecting the plant and means of distribution which should be put down by a municipality, so as to insure an absolute continuity of cheap electricity supply, and at the same time bear the severe practical test of enabling the manager and the rest of the officers who have to work during the day to go home comfortably to their five o'clock tea without expecting every moment to be rung up on account of some mishap or other.

In connection with this battle of the systems must be decided the proper voltage of supply to be adopted by works to be erected in the future; also whether it is advisable, and if so in what stage of their progress, for works in actual operation to raise their voltage of supply, and the best method of effecting a change. I only wish I could see a chance of our discussing within the next year or so such specially interesting technical problems as the advisability of earthing the neutral conductor of a low-tension system of supply, the most suitable class of mains to adopt, the proper size of feeders and generating units, the advisability of adopting for commercial, if not technical reasons, one uniform periodicity for alternating current plant, the wisdom of interconnecting all the low-tension network of a town, &c. Although the question of the best design for an electricity works depends so much on local circumstances, yet the main considerations affecting this ought now to be determined.

The question of locating faults on a system of distribution is another point on which we must all derive benefit by comparing our different methods and difficulties. Up to the present, busy men in practice have been apt to keep their various methods too much to themselves, forgetting that probably the combination of other methods with their own would be of great value. As it has now been recognised that the present system of wood casing for interior wiring cannot be considered finality either from an electrical or æsthetic point of view, a paper on this subject up to date would be most interesting and useful to all of us. Again, the best means for lighting streets, wide and narrow, can now, with the experience of many of our members, be advantageously discussed.

Our constitution has been framed on a very liberal basis, and I trust we shall escape the internal troubles which some of the older societies have had. On Friday we proceed to elect from among our members a president, two vice-presidents, three members of committee, a treasurer, and a secretary. In conclusion, I feel sure that if we can only persuade ourselves to be mutually communicative and ready to exchange our views and experiences, the result will be so beneficial to the community at large, that they will be as thankful to the members who first took up the idea of forming this Association as we ourselves ought to be to Mr. Magden, our first very energetic honorary secretary, who by his ability in organisation has done so much towards making this Association promise to be a permanent and useful success.

Sir Courtenay Boyle made a very interesting speech. He said he was very agreeably surprised at the tone of the papers and discussions. He thought they would be very valuable, both to the State Department which he represented, and also to municipal bodies. They were all working for the consumer, an individual whom he had heard mentioned by various speakers with great respect. They had, of course, to look to the consumer to approve their actions. He pointed out that the science they were dealing with was still young. It had been stated that the Board of Trade regulations were still defective. He was sorry to hear that said, and he felt that his Department must rely upon the opinions expressed at such a convention in order to improve the regulations. He had two matters to put to the meeting: (1) Can no one find a suitable name for a Board of Trade unit? He had hoped that the word "Kelvin" would be adopted, but Lord Kelvin had felt unable to accept the proposal, as he was personally interested in an electricity meter. (2) The Board of Trade must rely upon the gentlemen present and others in like position to guide them as to the selection and approval of good electricity meters. His friend, Major Cardew, could, of course, make the most careful and accurate laboratory tests, but they needed also to know how the meters acted in ordinary everyday work, and whether the readings remained constant. The Board of Trade had found considerable difficulty in these matters, and he thought that the engineers and municipal bodies would be the proper persons to assist his Department with valuable advice.

Our space will not permit of reproduction of the papers, but we shall deal with them in our issue of next week. Many of the points raised are of great interest to electrical engineers.

PETROLEUM MINES IN ROUMANIA.—The Berca-Paclete petroleum mines, in the Buzio district of Roumania, are reported by a correspondent of the *Echo des Mines* to possess a well, which alone yields, from a depth of 210 m.—114½ fathoms—on an average 20 tons daily of a petroleum which, in its raw state, burns with a flame like that of refined paraffin

TRADE AND BUSINESS ANNOUNCEMENTS.—Messrs. James Cleminson and Son, of Dashwood House, New Broad-street, announce that they have resumed their original telegraphic address, namely, Cleminson, London.—Messrs. Chamberlain and Hookham have appointed Mr. J. G. Statter, electrical and mechanical engineer, late of Victoria-street, to be the head of their dynamo factory.

NAVAL ENGINEER APPOINTMENTS.—The following appointments have been made at the Admiralty:—Engineer: James H. D. Barry, to the Hawke, to date June 5th. Assistant engineers: Clifford Howle, to the Vulcan, temporary, to date June 5th; Albert J. Kenning, to the Repulse, temporary, to date June 6th; Cyril E. J. Hammond and Ernest E. Pethick, to the Vivid, supernumerary, for disposal, to date June 6th.

CITY AND GUILDS OF LONDON INSTITUTE.—Those of our readers who have been fortunate enough to receive an invitation to the conversazione to be held at the Central Technical College, Exhibition-road, S.W., this—Friday—evening, will find a large amount of food for reflection and study. Practically the whole of this vast and well-arranged college will be thrown open to the visitors. The department of civil and mechanical engineering, under the direction of Professor W. C. Unwin, F.R.S., M. Inst. C.E.—who is also the dean of the college—including the engineering workshops and laboratory, the boiler-house, the calorimetric laboratory, the material testing laboratory. The cement testing laboratory will be open for inspection, and engineers will find in this section alone quite sufficient interesting material for one evening. In addition, the departments of mechanics and mathematics, presided over by Professor O. Henrici, F.R.S.; physics and electrical engineering, under the direction of Professor W. E. Ayrton, F.R.S.; chemistry, the head of which is Professor H. E. Armstrong, Ph.D., F.R.S., will put on view all their most interesting appliances and processes, while there will also be the inevitable demonstration of the use of the *x* rays in photographing and observing otherwise invisible objects.

THE FLUTOMETER.—Under this title Messrs. Simonsen, Nielsen, and Wedum, 28, Masshouse-lane, Birmingham, are introducing into this country an instrument of which, we understand, 8000 have been sold on the Continent. Its object is to indicate the amount of draught in the furnace and flues of a steam boiler. It consists essentially of a counter-weighted vane movable about a spindle within a cylindrical casing, and combined with a pointer moving over a dial, by which the deflection of the vane under the influence of an air current induced through the casing by the draught in the chimney or flue is indicated, the degree of deflection being a measure of the strength of the current, and consequently of the draught. The casing has an inlet and an outlet at opposite sides of a partition, and the outlet is adapted for connection with the chimney or flue of which it is desired to measure the draught. The instrument is generally fixed in front of the boiler on a tube, leading into the draught hole, it does not matter where, as long as it is below the dampers. If the tube is hammered through the wall any mortar or dust must be blown out before the instrument is fixed. The necessary degree of draught to keep up a good fire without wasting coal depends, of course, upon the size of the boiler, but when that is once ascertained the flutometer will always indicate whether there is too much draught or not. An excessive air admission is, of course, very wasteful of fuel.

LETTERS TO THE EDITOR.

We do not hold ourselves responsible for the opinions o: our correspondents.)

PERMANENT WAY.

SIR,—I would not presume to refer to your leader in last week's ENGINEER if I were not perfectly satisfied, from a long acquaintance with your estimable journal, of your fairness and impartiality in all matters that come under your notice. But while I consider you are perfectly right in the importance you attach to the proper use of ballast, I think you might insist somewhat on the value of other items involved in the construction of permanent way. I say this because, with all the well-known advantages belonging to "ballast as is ballast"—and good ballast is often the saving clause where much else is bad or imperfect—there is no item in any department of railway administration that will so surely hold its own as the various kinds of ballast now used, from humus to broken stone, together with the manner of its manipulation, and a very plausible excuse may be advanced for this.

In venturing to address you again, Mr. Editor, upon this subject, I promise you I will be guided by Montaigne, and only "write about what I know," and not with my "little pittance undertake to write a whole body of physics;" therefore, you may believe me when I say, that of all the difficulties that present themselves to the railway constructor—taking precedence even of what kind of foundations are to be obtained for his structures—the item of ballast stands out with the greatest prominence, and often gives rise to a good deal of anxiety. The biggest lump of a cutting, which is sometimes the key to the length of time required for the execution of the whole work, is just a matter of calculation; how many "roads" may be got to attack it, and how many wagons and "sets" of them can be got out of it per day, and the thing is done to the hour. Bricks may be made on the spot, and stone and wood and other material are nearly universal; but ballast, if not never, is certainly hardly ever to be found just where it is wanted, and just what it should be when found.

If often fortunately happens that rock cuttings occur where all the bottom ballast required for the line may be saved, even if attended with some inconvenience in the matter of long lead in its distribution; and some small stone, kept back from tips, with more broken stone in the absence of anything else, will be made use of as top ballast. But stone-breaking is to be avoided, as it costs money; and I have seen, at home and abroad, where, rather than go to this expense, much has been risked with other material that has been used in ballasting.

When the railway is constructed and handed over to the company, the "crux" is only transferred, and, if possible, with increased difficulties attending it. If it should happen that the line pass through strata such that as, with some attendant twinges of conscience, the contents may be accepted as ballast, then the line is provided for all future repairing needs, with pits conveniently situate on the sides of it at various places. Now, is it likely that the stuff which sometimes presents itself in such situations will be very closely scrutinised? No! And why? Because another material got from a distance, or off the line perhaps, as good as it really ought to be, would cost more in the getting it.

You have said that "Railways are slow to lead ballast from a distance." That is true, and it is also true that they will never get it from a distance; although not to do so should be demonstrated to be, as you say, "penny-wise-and-pound-foolish." And it will remain so until pressure is put on, and it may come to that eventually.

You say also, "What would a railway company be reimbursed if it doubled the number of sleepers in every mile of the track?" May I ask any of your readers, or anyone who knows only a little more than his multiplication table, whether, if there had been more sleepers on the track at Little Bytham, even with no more ballast about them than common, every additional sleeper would not have gone a little way toward rendering that road safer than it proved to be, even though the number should not have been doubled?

The recompense to be obtained also may really be a negative one, but it nevertheless assumes a very positive aspect when the cost is dotted down in the account books of the line, after the accident takes place. And is reputation for safety and freedom from disaster to be considered as no recompense at all?

My early training, more than half a century ago, was all in the direction of railway work, until opportunity interposed, and I became a telegraph engineer instead of a railway engineer. After some work in England, I went to the United States of America to serve a big telegraph contractor, but in a short time found myself engaged in railway instead. While still occupied in telegraphy, however, and impressed with the miserable state of the permanent way on the many miles of railway I had gone over on foot, I caught the American fever of racing with the locomotive, and for that matter steamboats too; and as one hundred miles per hour were freely talked about, I became "enthused," and voted boldly for one hundred miles; and, moreover, I advertised in the *New York Tribune* newspaper—1851—that I could suggest the construction of a road which should be safe at that or higher speeds.

In a country in which a man could obtain a patent for the simple re-arrangement of the rails of the well-known Virginia snake fence, I thought I might even obtain one for my road; but this illusion was dispelled. Therefore, as per advertisement, I published the fact that I was willing to give such information to whomsoever it might concern. There was no lack of interest shown by Americans, including some well-known railroad men, who actually had the uncommon modesty to think that it was possible to learn something from somebody else. But when I asked for three times as much iron, and nearly three times as much wood as they were then using, together with some other trifling adjuncts, they did not laugh at me, but said that all the iron used on their railroads came from Great Britain, perhaps a thousand to fifteen hundred pounds worth per mile, and that it was always paid for with paper "stock" pretty freely issued; consequently, extra expense was to be avoided, even if the British capitalist would—which was not likely—take a greater responsibility upon himself; therefore my road was not to be thought of.

I must say it, to the very great credit of the American, that my idea was not ridiculed; and while some said that perhaps I was right, none said I was positively wrong in any detail; others said I was quite right, and more than one, who knew what they were talking about gratified me by saying that what I proposed would some day come to be the general practice, "but it would be of slow growth, and then only as it was seen to be necessary from time to time." I might have seen how the thing would have to be evolved, and not be made a new creation at once; and it has come to this at last, as they said it would; but my enthusiasm in the matter was excusable, for I was very young then.

Now for another little matter, Mr. Editor, which is suggested by your own leader and the remarks of several correspondents in the last two weeks' ENGINEERS. I was so taken with the "bogie" on the other side of the Atlantic, that on my return to England in 1853 I saw some eminent engineers on the subject of its introduction here. One of these gentlemen happened to be an old personal friend, and one other to whom I was introduced in order to relate my transatlantic experiences, heard me out with evident impatience. My friend knew me well enough to take the liberty of concluding his opinion on the affair by telling me that I "knew nothing about a locomotive," and I was about as successful with the other, who was a much more eminent man. He said, "If my head never aches until the advantages of the bogie truck are recognised in England, I shall consider myself to be the most lucky of men."

I only relate this circumstance as affording a little side light on that conservative disposition—not to give it a more decided term—which can be evinced by really good men. Not being myself quite satisfied with their verdicts, I thought I would take my case to a higher court, and so wrote a letter to the *Mining Journal*, and it appeared in the issue of April 9th, 1853. If you will be good enough, Mr. Editor, to allow me, I will just select two short paragraphs from it to be reproduced here.

"My business has taken me on railroads in the United States for two years or more, and I believe that no English carriage would keep the rails for a distance of ten miles, at the rate of twenty miles per hour, on half the roads I have travelled in America at thirty and forty miles in safety, and I have been from Maine to Missouri. If I have shown that inequalities in the permanent way, or small curves of great length, do not necessarily cause accidents, it is that you may know the reason for it. The Americans mount their carriages, &c., on trucks of four wheels, each having a bearing of 2ft. 7in. only. Sufficient explanation.

"McConnell's new engines may 'run from London to Birmingham in two hours or less,' until they run off and kill. I will only say that if these engines were fitted on trucks, drawing carriages mounted also on trucks, the public need not fear one hundred miles an hour, even with our present permanent way."

In view of what we all know is done with the bogie now, and which, I regret to say, the two gentlemen of whom I have spoken above cannot realise, as they are, unfortunately—or fortunately, perhaps—beyond the reach of all "headaches," I can only refer with some satisfaction to the estimate I had of it so early in the day, in order that I may "point the moral" that it is unwise to overlook any item that may possibly be of use in the domain of railway administration, for whatever reason or from whichever side it may come.

J. W. WILKINS.

June 8th.

THE LIGHT RAILWAYS BILL.

SIR,—I agree with your remarks in your issue of June 5th, that the Government should define in this Bill what is meant by the term "light railway;" but I think you have fixed the axle weight too low when you stipulate for five tons. Several light railways will be built on the standard gauge, and this limit will prevent, say, a truck of coal from passing over such a line. I venture to suggest that the following definition will meet all requirements, viz., that the words light railway shall mean:—

(*a*) A railway constructed on a gauge of 4ft. 8½in., at a cost not exceeding £3500 per mile, including equipment, with a rail not exceeding 50 lb. per lineal yard, and worked at a speed not exceeding twenty-five miles per hour; or (*b*) a railway on a gauge of, say, 2ft. 6in., constructed and equipped at a cost not exceeding £3500 per mile, with a rail not exceeding 41½ lb. per lineal yard, and worked at a speed not exceeding twenty-five miles per hour. In the case of (*b*) the gauge should be fixed by Parliament so as to prevent a multiplication of gauges in different parts of the country.

J. C. MACKAY.

28, Victoria-street, Westminster, S.W., June 8th.

SIR,—Referring to the article in THE ENGINEER of the 5th inst. on the above subject, I find a light railway is defined in 31 and 32 Vic., Cap. 19 (Acts for Regulation of Railways, 1868) section 28, as follows:—

"A light railway shall be constructed and worked subject to such conditions and regulations as the Board of Trade may from time to time impose or make; provided that (1), the regulations respecting the weight of locomotive engines, carriages, and vehicles, to be used on such railway, shall not authorise a greater weight than eight tons to be brought upon the rails by any one pair of wheels; (2), the regulations respecting the speed of trains shall not authorise a rate of speed exceeding at any time twenty-five miles an hour."

I suppose this definition will stand if the new Light Railway Bill becomes law.

J. M. BURKE, M. Inst. C.E.

Dublin, June 8th.

NAVIGATION OF THE THAMES.

SIR,—May I be allowed to reply briefly to the letter from Mr. Henry Law, which appears in THE ENGINEER of May 29th? He states that the top of the Thames Tunnel is more than 36ft. below low-water springs. This, however, does not alter the fact that the tunnel is an obstruction, with, I believe, only about 12ft. at low-water, as stated in my previous letter.

While the tunnel remains it seems to me it will be an obstruction to the largest vessels. Does Mr. Law think the depth of the ground over the tunnel can safely be much reduced, or sufficiently so for the largest vessels?

A. SCOTT.

Newcastle-on-Tyne, June 4th.

PUFFING BILLY.

SIR,—I see two letters on Puffing Billy in your issue of May 29th ult., but I think few people are aware that an equally famous locomotive, no less than Puffing Billy's own twin-brother Wylam Dilly, is now preserved in the Royal Museum of Science and Art in Edinburgh. The everlasting separation of these old companions, in the interests of knowledge, in our two metropolitan cities might move some of your poetic readers to verse commemorative, seeing their names lend themselves to rhyming.

NORMAN D. MACDONALD.

15, Abercromby-place, Edinburgh,
June 3rd.

NORTH-EASTERN RAILWAY CARRIAGES.

THE trial run has taken place of the first of a number of entirely new trains which the North-Eastern Railway has built for the more important traffic on its line, and which present a number of great improvements and evince the desire of the company to be well "up-to-date" in matters affecting the comfort and safety of its patrons. The run was over the line between York and Scarborough, and proved in every sense successful, this route being chosen because of the number of sharp curves and the varying gradients, which enabled the officers—among whom were Mr. G. S. Gibb, the general manager; Mr. J. Welburn, the superintendent of the line; and Mr. Raven, the assistant locomotive superintendent—to satisfy themselves that the coaches could pass round the curves at a high speed with the utmost ease and absence of jolting.

Each train consists of five coaches, namely, two combined brake and third-class coaches, one third-class coach, one first and third-class lavatory coach, and one luggage composite coach. Each coach is 52ft. long and 8ft. 6in. wide—or 6in. wider than a standard coach—and is carried on a pair of four-wheeled bogies. These bogie trucks have been very carefully designed, and are constructed of flanged steel, with laminated bearing springs, and Timm's spiral bolster springs, which, while they allow the coach to take the curves with ease, at the same time eliminate the disagreeable vibration and noise which are inseparable from the old six-wheeled rigid coach, with its wheels fastened to the frame. The underframe has been built on an entirely new plan, the object in view being greater strength, combined with lightness; and for this purpose it is constructed of steel channel-iron soles, with cross rails of angle iron riveted to corner plates on the channel irons. The coaches are equipped with powerful laminated buffing springs, and the continuous draw-gear has india-rubber springs.

The body is made of mahogany, finished externally with the rich standard lake paint with yellow lines, and the N. E. R. coats-of-arms. The external appearance is very handsome, owing to the clerestory roof which runs the whole length of each coach, and gives a feeling of height and massiveness, rising as it does to a height of 13ft. 5in. from the rail level. The train is lighted throughout by Pintsch's patent gas, two lamps in each compartment, thus giving ample light. Every wheel of the train is fitted with double blocks of the quick-action Westinghouse brake, an improved brake, practically instantaneous in action, and which at the elaborate brake trials carried out on the North-Eastern Railway last year proved itself capable of stopping a train running at sixty miles an hour in 100 yards less distance than the brakes hitherto used in this country. It will be readily seen that such an advantage is of immense value for preventing collisions, and the public will be glad to know that the North-Eastern is the first company in Great Britain to adopt it as its standard brake.

Internally, the woodwork of the first-class compartments consists of brown oak facings with sycamore panels cross-banded with figured Kauri pine, the door panels being solid brown oak. The seats are trimmed with blue cloth and finished with red and black lace, the walls being decorated with four groups of photographs and bevelled edged mirrors. The third-class compartments are trimmed in red and black rep with lace to match, the walls above and at the sides being faced with millboard painted in cream and brown, which does much to deaden the sound. The groups of photographs of North-Eastern Railway scenery, framed in wainscot oak, are placed under the racks. The whole of the floors in the trains are covered with patent Kork matting, which is both noiseless and very warm for the feet, and each compartment is amply supplied with patent torpedo air extractors. The interior of the coaches is both light and airy, owing to the high clerestory ceiling with its separate windows, entirely doing away with the feeling of depression so common in a small railway compartment; and the large ventilators in the clerestory should be of much use in keeping the atmosphere fresh.

In the brake and third composite there are three third-class compartments and a large guard's van; the third-class coach has eight compartments; the luggage composite has three first and four third-class compartments and a luggage van; the lavatory composite has four first-class and three third-class compartments connected by corridors with the lavatories. These corridors are panelled in oak and sycamore above, and with old gold Lincrusta-Walton below. The lavatories are complete with tip-up basins, mirrors, towel racks, &c.

From the above brief description it will be seen that the coaches have been designed with the utmost care, and present several marked features of advance on the standard of coach hitherto used for ordinary trains, and indeed they reflect great credit on Mr. David Bain, the carriage superintendent, under whose supervision the work has been executed at the North-Eastern carriage works at York from designs prepared by the locomotive superintendent of the company. The train will be brought into service between Leeds and Scarborough, commencing 1st July.—*Newcastle Daily Chronicle.*

THE INSTITUTION OF CIVIL ENGINEERS.

THE annual general meeting was held on Tuesday, June 2nd, Sir Benjamin Baker, K.C.M.G., the president, in the chair. The report of the Council for the session 1895-96 dealt first with the changes that had been effected during the session in the charter and the bye-laws. The question of the constitution and the mode of election of the Council had received careful attention from successive Councils since 1888. The outgoing Council had been of opinion that the existing circumstances rendered changes in the constitution and the mode of election of the Council desirable in the interests of the Institution. That view having been cordially concurred in by the members generally, the Council had recommended that a supplemental charter should be applied for. At a special general meeting held on the 6th February last, a petition to her Majesty was duly adopted, and a new supplemental charter was granted on the 20th March. At a special general meeting held on the 15th April, the bye-laws were altered to bring them into conformity with the powers thus obtained. Under the new charter the members of the institution are at liberty to fix the number of the Council by bye-laws from time to time—thus admitting of the full and proper representation of all engineering interests both at home and in the Colonies and India—whilst in voting for the election of the Council personal attendance is no longer necessary.

The tabular statement of transfers, elections, deaths, and resignations during the year showed an effective increase of 109 on the previous total of 5,921, while the number of students was 877 as against 816 at the corresponding period of last year. The gross numbers on the books on the 31st March in 1895 and 1896 were 6737 and 6907 respectively.

During the year the following amounts had been received:—Income, £21,778 17s. 3d., of which £17,847 14s. 6d. represented subscriptions, £1705 19s. 5d. miscellaneous items, and £2225 3s. 4d. dividends; capital, £24,359 2s., of which £20,690 18s. 6d. was derived from the sale of stocks to meet expenditure on the new building; and trust funds account, £474 15s. 8d., making a total of £46,612 14s. 11d. The expenditure amounted to £53,334 0s. 11d., allocated as follows:—Income, £17,074 7s. 9d., including £9061 13s. 1d. for publications; capital, £35,935 12s. 2d., of which £34,205 12s. had been absorbed directly by the new building, while the remainder represented incidental expenditure incurred in connection therewith; and trust funds account, £324 1s.

The first meeting of the session had been held in the new building on the prescribed day, when the President delivered an address to a very large audience, 598 names being recorded in the attendance book. There had been twenty-three ordinary meetings, at which nineteen communications had been read and discussed, covering a range as wide as that comprised in Tredgold's well-known definition of the art of the civil engineer.

In recognition of the merits of some of the papers awards out of the funds appropriated to that purpose had been made to Messrs. George F. Deacon, H. Riall Sankey, J. A. Ewing, J. O. Arnold, G. H. Hill, Jeremiah Head, E. L. Corthell, R. C. Parsons, H. Heenan, W. Gilbert, T. Wrightson, and H. F. Parshall. The papers printed without being discussed treated as usual a variety of subjects, and, in recognition of the labours of some of the authors, premiums had been awarded to Messrs. Brian Donkin and Alan Brebner for papers published in vol. cxxii. It was stated that the awards in the case of selected papers published during the session 1895-96 would be announced at the opening meeting of the next session.

The fourth annual lecture of the "James Forrest" series—"Physical Experiment in Relation to Engineering"—was delivered by Dr. Alex. B. W. Kennedy, F.R.S., M. Inst. C.E., on the 7th May. This discourse would be printed in the concluding volume of the "Proceedings" of the session.

The attendance at the supplemental students' meetings had shown some improvement, the average having been 48. Several papers of merit had been read and discussed, and Miller prizes had been awarded to Messrs. W. O. Leitch, jun., A. S. Butterworth, E. S. MacDonald, and S. Thow. Awards of Miller prizes had also been made to Messrs. J. Scott and J. Andrew for papers read before the Glasgow Association of Students, and to Mr. M. De Ville for a paper read before the Manchester Association.

The report having been adopted, cordial votes of thanks were passed to the president, the vice-presidents, and other members of council for the services they had rendered during the past session; and to the auditors and the scrutineers for the time and trouble they had devoted to their respective duties. Messrs. A. C. Hurtzig and J. G. Griffiths were appointed auditors for the ensuing session.

The ballot for council resulted in the election of John Wolfe Barry, C.B., F.R.S., as president; William Henry Preece, C.B., F.R.S., Sir Douglas Fox, James Mansergh, and William Anderson, C.B., D.C.L., F.R.S., as vice-presidents; Alexander Richardson Binnie, Henry Deane, William Robert Galbraith, George Graham, James Henry Greathead, John Clarke Hawkshaw, M.A., Charles Hawksley, John Hopkinson, jun., M.A., D.Sc., Wh.Sc., F.R.S., Alexander Blackie, William Kennedy, LL.D., F.R.S., John Kennedy, George Fosbery Lyster, Sir Guilford Lindsay Molesworth, K.C.I.E., Captain Sir Andrew Noble, K.C.B., F.R.S., late R.A., William Shelford, Bindon Blood Stoney, LL.D., F.R.S., Francis William Webb, Sir William Henry White, K.C.B., LL.D., F.R.S., and Sir Edward Leader Williams, as other members of council.

The next session will commence on the first Tuesday in November.

THE FUNCTIONS OF THE ARMY AND NAVY ON THE DEFENCE OF THE EMPIRE.

UNDER this title Admiral Colomb has read a paper at the United Service Institution, Earl Cowper being in the chair, to an audience containing many high authorities on the subject. The lecturer said the conclusion that he wished to establish was that we have laid too much stress on the defence of isolated positions, and not enough on the idea of mobile forces, naval and military, connecting the positions and throwing their whole strength on any point seriously threatened. The Navy, he said, had escaped the drag upon its mobility which formerly beset it but the Army has not escaped it, and all through the Empire the drag of an immobile and isolated system of defence keeps the Army down, and makes insignificant a force that ought to be looked upon as a pattern in the same way that the Navy is so regarded by other nations. For example, in an Army return last March 13th, the charge for the effective Army in the United Kingdom is set down at £5,081,100, while that for garrisoned positions at home and troops in reserve is £3,677,500. Thus nearly four-ninths of the whole is for troops not intended to operate beyond the United Kingdom. Taking this as indicating a proportion between mobile and immobile forces, the lecturer held that the Empire was not safe with so small a force as is thus indicated as being ready to embark at short notice. He held that history teaches that we have long had the greatest Navy ever known, but an Army always insignificant at the point of contact, and consequently generally acting as an ally. This has been due, not to the fact that the money voted for the Army was small, for it has generally been greater than that devoted to the Navy, but that the money has been wrongly applied. The independent action, then, which the Army and Navy have taken in the past, has not hurt the Navy, but has seriously injured the Army.

The Admiral next divided the advocates of defence into two schools, which he termed the "instinctive" and "reasoned." The former seeks to defend everything on independent grounds. This school built the great wall of China and sea coast batteries which barbarians unkindly took in reverse; it walled in Paris and shut up an army in Metz. It sunk immense sums in fortifying Portsmouth and Plymouth, and it pines to build a wall round London. The "reasoned" school looks on defence as a whole, considering that a force divided up in isolated positions, however strong, must yield bit by bit in succession to an equal force concentrated on each in succession, and pleads that history bears this out. Hence, this school seeks to prevent attack, or to meet it by mobile forces readily concentrated and thrown on to the threatened point. Thus the instinctive force does not take time into account, while, with the reasoned defence, time is everything, and beyond very small forces sufficient to prevent surprises, it depends wholly on the operation of mobile forces. The instinctive school in reality only secures delay. The reasoned school defies any attack not strong enough to deal with the mobile force.

If it is urged that isolated places can be made impregnable to attack, the reply is that it is sufficient to invest and starve them. The instinctive school acts on possibilities, the reasoned school deals with war as a speculative business, in which a prospective gain should be kept in view, greatly exceeding the prospective risk. It puts itself as far as possible in the enemy's mind, reflecting that his object is conquest and occupation, plunder, or lastly, destruction. The first requires assured, permanent communication, and fails when the place is afterwards surrounded and cut off; and the two last require communication for a certain time, which the reasoned school operations should forbid.

To apply these principles in the case of the Empire: the British Empire consists of many positions divided asunder by great or little bands of sea. An enemy's business is to isolate them by its navy, if possible, while land frontiers may be invaded by an enemy's army if not prevented. No one denies to such a case the application in some measure of the action of mobile forces, naval or military. No one, for example, would free the mobile army from the duty of going to the frontier of India or Canada. As to the sea frontiers, the contention arises whether to attempt local defence by forts or coast defence ships, or to depend on a great mobile naval force. Thus we now depend on ships in squadrons or groups, near the United Kingdom, in the Mediterranean, Chinese, Indian. African, Australian, and American waters. Experience tells us what are the first steps taken by our Navy on threat of war. This is, we "shadow" the warships of the enemy everywhere by equal or superior forces in all neutral ports. Watching an enemy's own ports is an actual act of war. At a station where no force of the threatening enemy exists, the ships are assembled at some central and convenient rendezvous. An enemy to obtain success must be prepared to beat any group of ships within reach, or he must only attempt surprises on a very small scale. If he falls back into his own ports blockade follows, which, if complete, constitutes a complete defence to the Empire. The Army may keep an enemy's ships at bay till a defending force arrives; the probable time of its arrival may be such as to prevent the enemy attempting attack at all. The strength of a garrison, then, should be proportioned to its distance from the place of concentration of the naval force. If the enemy breaks blockade he must be followed.

The lecturer then pointed out the fallacy of the phrases, "The Navy is our first line of defence," and "Liberation of fleets for attack the true defence." The former, he said, appears to be based on the false conception that the British Islands are guarded by a sort of chain of ships. The latter is false because the Admiral of a fleet would always endeavour to strike any equal or inferior fleet within reach. It would be hopeless for him to excuse himself by declaring that he believed places behind him were insufficiently fortified and garrisoned. An Admiral should meet any flotilla about to sail, if possible as soon as it puts to sea, and any known weakness of his country's land defences should especially prompt such action, and only distinct inferiority in strength could justify any other course.

Again, modern changes in war material rather emphasise the above, such as great increase in speed, improved supply of intelligence, and the substitution of steam power for wind; so again, do increased power of gun fire, increased cost of warships, the rise of the torpedo and submarine mine. From these result greater certainty for a defending force in striking, while an attacking force is limited to a certain radius of action from its centre of supply. The transports of an attacking force are specially open to destruction by torpedo vessels and rams. Blockade and the watch of an enemy's ports ought to be facilitated by the above, but unless this be more effective than formerly, commerce still remains open to attack chiefly in the vicinity of commercial ports. Here the action of localised defended ships may come in, which, supported by batteries, might keep a foe at bay until reinforcing cruisers arrive; but it is not now possible for a cruiser to see an enemy capturing ships which the direction of wind makes it impossible for her to assist. In the face of a superior navy, night attacks on shipping by torpedo boats and the like will not develope greatly, but may be expected early in a war, and here the joint defence by Army and Navy should be close and intimate.

To come to actual features, the United Kingdom is of all parts of the Empire least liable to attack as the heart of empire and great rendezvous of naval forces. The prevention of landing, not the disposal of an enemy after landing, is the great matter. Lord Overstone has warned us that the landing itself, not what would follow, would bring about a financial collapse, yet sums of money sufficient to supply quite a fine mobile army have gone chiefly on preparations for fighting an enemy after he has landed. The invasion of such a country as Great Britain necessitates immense preparations, and renders secrecy and surprise impossible. This was pointed out over 100 years ago, when a French fleet had once been actually seen from Plymouth, and when our own fleet had been sent out for a two months' voyage each year. The study of the subject of invasions would convince anyone of the impossibility of conducting it on a large scale suddenly.

The lecturer then considered the position of a general landed in England with 100,000 men, and marching on London, on reaching the area covered by streets, with 500,000 troops in the island gathering to attack him, backed by the whole civilian population available for street fighting, and he dwelt on the impossibility of his reaching or overawing the mass of those gathered round the locality. As a fact, the lecturer questioned any serious invasion of England being attempted, except one based on meeting with allies among the English themselves, and did not believe that even 20,000 men could be landed on the shores of the British Isles without being opposed at sea.

It is sometimes urged that possible distributions of our naval forces might give an enemy time to land unopposed. Two occasions are quoted, one in 1878, when the Mediterranean fleet passed the Dardanelles, and one in 1882, when it attacked Alexandria, but in the latter case the fleet could proceed to Spithead as immediately as if it had not been in action. It should also be pointed out that in 1878 there was a home fleet in commission of seventeen battleships, five cruisers, twenty-three gunboats, eight smaller vessels, and two torpedo boats, besides fifty sail, including ten battleships completing in the Reserve. In 1882 there were at home in commission seventeen battleships, one cruiser, twenty-one gunboats, eight small vessels, and nine torpedo boats. Complete in the Reserve were ten battleships, seven cruisers, eleven gunboats, and eighteen torpedo boats. Besides, there were forty-two sail, of which five were battleships completing in the Reserve.

The development of the torpedo vessel puts the possibility of invasion further off, and the crowd of tugs and smaller vessels ought to make short work of transports crowded with troops by ramming them; indeed, the dangers now besetting a transport are such that the lecturer did not know how an admiral could guard against it. Isolated attacks of ports or harbours have become more difficult, since steam and telegraph have given power of rapid action to a defending force.

That which is true of the United Kingdom on a great scale applies on a smaller scale all over the Empire; that is, let the mobile defending force be greater than the enemy, and the local defending functions of the Army are greatly diminished. A defending mobile military force, however, should be collected on the same principle as in the United Kingdom. Let it be apparent that a port would take longer to subdue than would suffice for the arrival of the mobile defending force, and attack would not be attempted. The highest functions of the Army, it may be noted, must ever be in inland operations. An enemy to benefit by plunder must be left free to carry it home. To undertake destruction is serious for an inferior Power, because reprisals will be measured out to it on a multiplied scale.

The lecturer pleaded, in conclusion, that he had established a *primâ facie* case for a large and mobile army to be obtained by suppressing exaggerated ideas of localised and immobile defences. He trusted that it might be clearly understood, however, that he was not dealing with that death struggle which may occur in distant parts of the Empire if ever the power of mutual help is destroyed by the suppression of the Navy. This conjuncture the lecturer declined to consider until some other authority has done so, or so soon as he saw preparations for it going on.

In discussion Field-Marshal Sir Lintorn Simmons said that undoubtedly the dangerous weakness of the defences of England that had been pointed out by the great Duke of Wellington had been remedied in important respects, our fleet being much stronger than in his day and our force of volunteers having been established; but he considered that the lecturer had treated intelligence as more certain than it would be in war, when cables might be cut. He was not satisfied that we could safely detach squadrons of ships as suggested without defences behind them. He recommended the investigation of the whole question by a Commission. Capt. James, late R.E., supported Sir Lintorn Simmons in pressing the need of a Commission, but, while he believed that our mobile force was too small, he questioned if it could be increased by sweeping away our auxiliary forces. Mr. L. Swinburne urged that an admiral would be more free to strike with a defended base. General Sir H. Smythe, R.A., urged that the great importance of the British Isles as the heart of the Empire and main rendezvous of our forces was of such paramount importance that the strength of its defences ought to be secured in a measure out of proportion to the other parts of the Empire. Admiral Close commended Mr. Balfour's proposal of a Minister of Public Defence. He noticed the difficulty of getting naval and military authorities to accept advice from each other when an actual point arose, although in public in general terms they expressed the desire to do so. Admiral Fitzgerald expressed his conviction that there was nothing in Admiral Colomb's paper that anyone seriously differed from. He failed, however, to understand a remark that counter attacks were imaginary either by land or sea, and said that the lecturer might have read in the history of his own country a striking account of simultaneous attacks being made by two chieftains with their forces on each other's strongholds, when they took different roads, missed each other, both going and returning, and each met with such complete success that they ended by having simply exchanged all their women and cattle.

THE MARITIME POSITION AND THE PRINCIPAL FEATURES OF THE PORT OF HAMBURG.*

By HERR FRANZ ANDREAS MEYER, Engineer-in-Chief of the Free and Hanseatic City of Hamburg.

IN the fifth century of our chronology a number of my Lower Saxon countrymen left, on three sturdy crafts, these lowlands to assist the Britons against the Picts and Scots. I cannot blame those Anglo-Saxons for not returning to their rude lacustrine habitations and dark forests of the flat North German coast; no doubt they found it more preferable to remain in the sunny isle of Albion surrounded by the blue ocean. These emigrants, though, have not been lost to their native tribe; on the contrary, they raised a race akin to us, who have always sympathised with them.

The mighty spreading of the Anglo-Saxon race, enabling Great Britain to become a pioneer in the civilisation of the whole inhabited world, was shared by the Lower Saxons of the German coast, as they had of old proposed similar tasks, at the period of the Middle Ages, especially those of the Hanse towns, of which the city of Hamburg claims its honourable name up to this day. Later on, at the time of the Reformation, when the political distress of our large and beautiful country took larger dimensions, Hamburg had to keep up its commerce under rather difficult circumstances, and it was at this period that the English achievement in successfully increasing civilisation was of great advantage to our town, as it could in many ways rely thereon. In Hamburg, where we are now reaping the good of a united Germany, we cannot therefore forget these advantages offered to us by our English neighbours, who are connected to us by the most intimate relations of commerce, customs, and religion, and thus we are delighted that a highly respected party of that nation have felt the necessity of paying us a visit, in order to find out what has become of the settlements of our mutual ancestors in the course of many centuries.

There can scarcely be anyone so aged among our most esteemed guests from Great Britain as to have personally any remembrance of the time of Hengist and Horsa, nor is any contemporary to be found here. The chronicles of that period having also preserved no record thereof, we can only suppose that at that time, on the spot where Hamburg now lies, no town-like settlement existed. The North Sea, without doubt, sent its waves far up the estuary of the Elbe, even up to the Saxon forest, where our great Altreichskanzler, Prince Bismarck, has now taken up his abode. In this wide bay the seafaring and fishing Lower Saxons could not offer any sheltered anchorage to their ships, but were compelled to moor them in the creeks which here discharge their waters into the Elbe from the Holstein Highlands. Their dwellings were to be found on the wooded and lovely banks of the Bille, coming from the Saxon Forest, and on the Alster, winding its way through Holstein, till Charlemagne, at the beginning of the ninth century, built a stronghold, very near the place of this assemblage, containing a cathedral—more or less an ecclesiastical Hamburg—the Holy Ansgarius being the first bishop. From the windows of the Patriotic Building may be seen the monument of this venerable man erected on the bridge called Trostbrücke, which crosses the oldest outlet of the Alster into the Elbe. On the other side of this oldest bridge the valiant Counts of Schaumburg, figuring in the Crusades as well as in exploits against the Danes, had their stronghold, the New Burgh, which the benignant Adolphus III. of Schaumburg sacrificed in the twelfth century to the Hamburg citizens for the erection of warehouses and the laying out of the first harbour. You will now see on the Neue Burg the offices of your associate Herr Laeisz, and in the place of a former chapel dedicated by fishermen to St. Nicholas, the beautiful Gothic structure of St. Nicholas Church, built by the eminent English architect, Sir George Gilbert Scott, after the great fire of 1842, the spire of which, having a height of 482ft.—36ft. less than the total length of the Hamburg-American liner Fürst Bismarck—is surpassed by only a few spires in the world.

By embanking the marshes situated further south, the town, including the harbour, was by degrees drawn out of the region of the Alster nearer to the Elbe. At the same time the river Elbe was brought nearer to the town by means of most ingenious cuttings. Everbody visiting Hamburg before the time of the grand structural changes called forth from 1883-1888, in consequence of incorporation with the German Customs Union, will surely remember the fine roads of the harbour stretching before the embankments of the river to the height of the Stintfang, and from its summit, which is crowned by the buildings of the Imperial German Observatory for nautical and meteorological purposes, they will not have forgotten the exquisite view over the harbour and the river.

The effects of the severe sufferings caused by the occupation of the city by the armies of Napolen in 1813-14, and the compulsory contributions levied on the inhabitants, may be traced far into our century, and it was only by the introduction of railways and steamships; by the removal of the fortifications restored by the French when in possession of the town; by the rebuilding of one-fifth of the city, reduced to ashes in the great fire of 1842, that those features were gained which give to our city its present appearance of a great maritime metropolis. The principal latest reorganisation has been made by transforming the harbours and making new commercial arrangements called forth by the Customs Union of the new German Empire, and these have only been finally completed within the last years. What we are aiming at now is a thorough rectification of the Lower Elbe to further improve navigation, and thus to allow big vessels of the latest type to pass the bar between Hamburg and Brunshausen. By effecting this the favourable situation of the largest continental seaport, even now accessible to vessels drawing 24ft. and upwards, will be completely utilised for universal trade. You will be able to form an opinion on this fact by my showing you the present arrangement of the port in connection with the means of conveyance. I shall, however, omit every historical retrospect.

At the mouth of the Elbe in the North Sea, the river has a depth sufficient for any draught. Coming from the Dutch Islands along the German coast, and keeping to soundings of 12 to 14 fathoms depth, you will be led safely into the mouth of the Elbe. Even above Glückstadt, *i.e.*, about forty nautical miles farther up from the proper mouth, the channel maintains throughout a trough-shaped character, running in two mighty concave-shaped lines. The lower one is directed towards the banks of the Hadeln and Cuxhaven; in its grandness it will scarcely be surpassed by any river in Europe. In this part of the river the North Sea-Baltic Canal—Kaiser Wilhelm Kanal—navigable for vessels up to 29ft. draught, enters from the right bank, and nearly opposite, at Cuxhaven, belonging to Hamburg, there has been laid out a grand tidal basin with a depth of 26ft. at ordinary low water and a tide of 9ft., allowing the largest steamships to enter and leave irrespective of conditions of tide. In the course of next year everything will be completed, and the greyhounds of our Hamburg-America line will then start from this point. Vessels with the deepest draught get up the Elbe now without lighterage as far as Brunshausen, sixteen miles below Hamburg. Up to Hamburg, vessels with a draught of 24ft. may always come up at normal tides, but the new harbour basins here have been constructed in such a manner that they may be deepened, the removal of the bar between Hamburg and Brunshausen being only a question of time.

As at Hamburg the ordinary tide rises only 6ft., all our harbours could be laid out as tidal basins. The estuary changing at our port—sixty-eight miles from the mouth of the Elbe—into the real bed of the river, it may be said that Hamburg is situated just on the right point of the river, as here the navigation of ocean vessels and river craft meet, and, therefore, allow transhipments from the ocean to the interior with great facility. By means of an upper course of 650 nautical miles in length, navigable far into Bohemia, in connection with numerous affluents and ship canals, the river Elbe has opened to the Hamburg trade a large interior of country, not only in the German Empire, but also in the Austrian Monarchy.

The importance of this position of the port of Hamburg, and the development of transhipment between ocean and river trade will be better apparent by the following figures. The tonnage of ocean vessels trading to and from Hamburg has increased in the last thirty years from 1,200,000 registered tons to 6,200,000 registered tons, and in the last twelve years doubled its amount. The quantity of goods passing from Hamburg to the interior by means of river craft has increased in the last thirty years from 330,000 tons to 2,400,000 tons; in the last twelve years even twice as much. On the other hand, the import of goods floating down to Hamburg is now yearly 2,000,000 tons.

That the shipping trade of Hamburg is equal to that of the largest seaports of the North Sea and the Channel will be understood by comparing the total number of seagoing vessels that arrived in 1894 at the following ports:—

	Hamburg.	Bremen.	Antwerp.	Rotterdam.	Havre.
Vessels	9,165	4,178	4,721	5,109	6,602
Registered tons	6,228,821	2,172,075	5,002,704	4,143,403	2,860,308

Of the above-mentioned vessels arriving in Hamburg, 6500, or nearly 70 per cent., are steamers with nine-tenths of the total tonnage. In some English ports these figures are surpassed, but then it must be borne in mind that in England coasting is done on a much larger scale. Excluding coasting traffic, the shipping trade of London is 50 per cent. higher than that of Hamburg; from this point of view the figures are, for vessels arriving from foreign ports in 1894, viz.:—

	Hamburg.	London.	Liverpool.
Vessels	6,354 ..	10,384 ..	3,873
Registered tons	5,699,547 ..	8,301,868 ..	5,492,327

The technical contrivances for the accommodation of vessels and for the handling of goods in Hamburg have assumed their present day appearance only after completely extending the system of railways in Germany about the year 1860. Up to that time, steamers were compelled to land or to receive cargo by anchoring in the river and discharging into barges, which brought their goods by means of numerous canals, to the different warehouses scattered in various parts of the town. I may add here that the arrival of the first steamer in Hamburg took place in 1816; it was the Lady of the Lake from your island.

In 1865, the first basin for sea-going vessels was dug out of trenches belonging to the former fortifications, and secured by a timber embankment. The quay was provided with open goods sheds, rails were laid connected with the terminus of the Berlin line, and the arrangement was completed by a number of portable steam cranes of the well-known Brown Brothers' type. Within ten years the flats of the Grasbrook were covered by basins of a similar kind, amounting in total to a length of twenty-six miles of quay walls, the old picturesque roads of the harbour with its forest of masts remaining still in use. When the city of Hamburg, in 1881, resolved to enter into the Customs Union of the German Empire, its old conditions of a "free city" underwent a change. An area of about 2500 acres of the port with its storehouses for transit goods was separated from the former business and residential city, and rebuilt into a uniform free port district. [The extension of this area is shown on the plan handed to you yesterday.] In carrying out this plan, the modern harbour construction was practically completed in connection with the inland railways, ending at the upper boundary of navigation for sea-going vessels, which is the bridge of the Hanover line of rails crossing the Elbe. At the same time the marshes on the left bank, which were previously laid up and extended to the boundary with Hanover, were included, giving in all 10·5 miles of quays for sea-going vessels with railroad tracks and sheds, the latter covering an area of 1,900,000 square feet. All harbours are open tidal basins, as much as possible parallel to the course of the river, and act at the same time as reservoirs for regulating the channel, while they narrow towards their entrances in order to avoid silting up at these points. The extensive quays are constructed of masonry, and provided with railroads, streets, long rows of sheds, and of late, with a great number of portable steam cranes, elevated upon large wrought iron frames, which span the rails, and allow the trains and cars to pass underneath. The largest crane of the port lifts 150 tons. For the future development of the harbours the western part of the left bank, which still belongs for a good way down the river to Hamburg, is reserved.

---

* Read at the summer meeting of the Thirty-seventh Session of the Institution of Naval Architects, June 9th, 1896.

The large Hamburg dockyards on the left bank, of which those of Messrs. Blohm and Voss and the Reiherstieg-Schiffswerft are especially prominent, are included in the area of the free port, thus keeping the vessels, whilst building and repairing, free of duty. The number of ships built and building in the yard since 1878 up to the present time is 121, including some 24 sailing vessels, all of which have a very good record for fast sailing. At present one steamer for the Hamburg-South American Steam Navigation Company of about 6500 tons deadweight is building, also two steamers for the German Steamship Outfitters Company of Hamburg of 7000 tons each, moreover two twin-screw steamers for the North German Lloyd, Bremen, one passenger and freight steamer of a length of 525ft. and 10,000 tons deadweight, and one of 4000 tons. Besides, the shipyard has just delivered for the Hamburg-Heligoland passenger service a light draught saloon paddle steamer with a speed of 16 knots. Finally, there is approaching completion a twin-screw passenger steamer of a length of 400ft. and 6000 tons deadweight, built to the order of the German East-African line, Hamburg. Also several large basins for the accommodation of river craft have been arranged in the precincts of the free port, in order to facilitate transhipments between sea-going vessels and river craft. Constant care is taken for the river service of our port, by reforming the courses of traffic, providing for new harbour basins within the Customs boundary-line, and by erecting landing stages. An extensive network of canals is connected with the tributaries Alster and Bille. These canals are situated in the embanked lower parts of the city, and are connected with the Elbe locks. By means of these canals, the transport of goods by water is made possible to many residential and business parts of the city, and to industrial works situated at a greater distance from the river, in the Customs Union.

During the period of the construction of the works necessary for the accession to the Customs Union, not less than 4·6 miles of quay walls for river service have been carried out mostly in embanking the Zollkanal, which separates the free port from the part of the city included in the Customs Union, and in embanking those canals bounding the warehouses of the free port. [Compare the red hatched part of the small plan.] Warehouses became necessary in consequence of the incorporation of the town into the Customs limits, in order to allow the merchants the storing of goods for their outward trade in connection with offices in the immediate vicinity of the centre of Hamburg trade, the ancient merchants' houses having been included within the Customs boundary. The space required for the said purpose was created by purchasing a certain portion of the town inhabited by 20,000 persons, upon which, after pulling down all houses, a building site was created measuring ten acres net. The warehouses of the free harbour territory are partly erected by a company—Lagerhaus Gesellschaft—partly by Government. They contain five to six stories and a cellar, each for warehousing goods, and are administered by the company above mentioned. They offer room for storing goods covering about 3,230,000 square feet surface, of an average bearing capacity of 1·5 tons per square yard of ground surface. For a further increase of the number of warehouses, which at present seems requisite, an area of about 5·4 acres has been reserved, called Wandrahm-Insel.

The central hydraulic power station of this town of warehouses possesses the energy of 500-horse power, and delivers the water at 711 lb. pressure per square inch, whereby it became possible, at the same time, to construct hydraulic-power hydrants for fire-extinguishing purposes in the streets and at all parts of the warehouses. In connection with this plant there is an electrical station of 970-horse power, and accumulator service for lighting purposes and motor service for the driving of machines used for the manufacture of goods. The canals between the said warehouses can only be used for barges. No direct connection has been established between the warehouses and the quays for sea-going vessels, for the reason that a sea-going vessel seldom brings goods for only one warehouse, and that she has to be quickly discharged and dispatched at one single berth, whereby the separation of goods has to be effected through an intermediate system of transport. Dwelling houses and retail trade are prohibited within the free-harbour territory. All roads situated inside the Customs boundary, both by water and land, are brought round the said territory, thus allowing passengers and goods to pass Hamburg without being submitted to any examination by the Customs authorities. Only passengers and goods arriving by sea are subject to Customs control as soon as they pass the free-harbour limits. Coffee and dining halls have been erected for comfort of workmen and officials employed in the free-harbour territory, the said halls being under Government control, and they sell goods whereon duty has been paid. The greatest part of the mercantile business is transacted inside the ancient part of the city, close to the free-harbour territory, the centre of which is formed by the Hamburg Exchange. In the immediate neighbourhood of the latter we have placed our fine new Town Hall, built in German Renaissance style.

The ancient city of Hamburg was formerly surrounded by very high fortifications, through which only five gates allowed exit and entrance. The population by degrees increased to such an extent that in some quarters of the city there dwelt above 400 persons to the acre, and even the reconstruction of the part of the town destroyed in 1842, after the great fire, did not alter this state of affairs. Only the wealthier classes used to live at their country seats on the lovely banks of the Lower Elbe, the Alster, and Bille rivers, sometimes at a good distance from the gates. In 1862 the population amounted to about 200,000 inhabitants. After the abolition of the old gate toll at that time, and after the decision to transform the high city walls by degrees into public parks, to be crossed by radial streets, there began an unexpected development of the organism of the city. It was almost like an explosion. Beyond all the gates the buildings extended like a stream, surrounding the Alster lake. Thus the old centre of the town was opened up by many straight cuts. By a removal of the wealthier classes towards the outside, and an increased erection of warehouses, Hamburg more and more adopted the character of the city of London, viz., a gathering of shops and offices, whereas the parts surrounding the outer Alster may well be compared with the West End of London. The parishes situated at a greater distance from the Alster, towards the neighbouring towns of Wandsbeck and Altona, show the character of medium-sized townships.

The population of the "city" decreases annually by about 1 per cent.; but on the whole the population of Hamburg increases, on the average, by more than 3 per cent. per annum, amounting at present to 630,000. It has almost been impossible for the municipal work to keep pace with this increase. A network of sewers has been spread all over the town, having a total length of about 230 English miles, whereby all drainage, including sewage, is passed into the strongest current of the Elbe below Hamburg. The water supply is regulated by means of a pipe-service to all parts of the town, about 325 English miles in length. The water is taken from the river a good distance above Hamburg, near the Billwärder Island, and the quality of it has been much improved by means of large settling and filter works erected within the years 1890 to 1893. Two large central stations, of together about 10,000-horse power, supply the town with electrical power for lighting and motor purposes by means of cables measuring about 150 English miles. They form a competition to the gas works, which supply the whole town and suburbs with gas. We are trying to make the gas available for heating purposes in order thereby to solve the difficult question how to get rid of the soot. A well-organised street-cleaning brigade, established ten years ago, looks after the cleanliness of public streets and squares, which measure, at present, in all 59,200,000 square feet. The said brigade musters 350 hands. For making house refuse harmless, we have recently erected at the Bullerdeich a "refuse destructor," containing thirty-six cells, after the approved English system of Horsefall, Leeds.

The ancient city walls, after the unhealthy and narrow streets situated behind them were pulled down, have been transformed into splendid parks, the last part of which is just now under construction, near the quarter of St. Pauli. The old pasture grounds, situated outside the gates, have been made available for football and tennis playing. However, the rapid extension of the town caused in many outer parishes a certain irregularity in the erection of buildings, rendering it necessary to establish an extensive plan for the laying out of new houses and streets within the town and suburbs. A new Act is now prepared in the interest of public welfare, limiting the speculation in new houses and the right of single individuals to erect buildings as they choose. The said plan for the construction of new buildings is intended to cover an area of 15,000 acres, and is based upon the supposition that the density of population, which, within the inner city, including the suburbs of St. Pauli and St. Georg, is on an average 200 persons per acre, shall not exceed 100 in the outer districts. It may be hoped that in this way may be furthered the old inveterate love of the Lower Saxons of residing in single buildings—in English fashion—which has been so badly checked within the last decades by the mania of house speculators for utilising the building site to the utmost degree for large tenements. It further appears most desirable, by leaving a sufficiently large space in front of and behind the houses vacant, to further as much as possible the cultivation of gardens and lawns which flourish so well in our moist coast districts. There also exists an absolute necessity to take greater care than hitherto in regard to the proper laying out of roads, including footpaths, considering the always increasing distances of the outskirts from the centre of the town and from each other.

We possess, it is true, an extensive network of tramways, measuring about sixty English miles in length, that portion worked by electricity being about fifty-two English miles in length, on which about 275 motor cars are driven simultaneously. However, although this method of transport is being steadily improved by the never-ceasing inventions in the field of electro-engineering, still it cannot master the traffic, even when supported by the steamboats on the Alster and the ferry-boats on the Elbe. It will be necessary to adopt different means, as in other large towns, to satisfy the want of quicker conveyance; also the banks of the river Elbe must be better connected by solidly constructed thoroughfares, either above or below sea navigation. From this prospective view of intended engineering works you will recognise, gentlemen, that labour never ceases. It is an old rule that life and rest exclude each other. This leads to the consequence that you never can build your house quite ready, it may then be the "old-age house," wherein you intend to end your latter days. I firmly believe, gentlemen, that Hamburg has no intention whatever to sit down as yet for her "old-age rest." As long as there is any space left at our disposal for harbour purposes, and as long as the river Elbe can be kept navigable from the mountains down to the ocean, so long there will never cease to exist at this place a brisk, industrious life, filled with trade and commerce. In what manner the city of Hamburg may—perhaps within a short time—have further developed by new schemes for trade and intercourse, or may be altered in consequence of new experience gathered on the field of national economy, I am unable to say, just as little as I can say how you will like the present features of our town.

And now, you gentlemen and dear colleagues who are not satisfied with a quiet and contemplative sphere of life, but who prefer a steady and unceasing progress in new building and construction, you may perhaps, I venture to hope, not even find it inconvenient if you fail to meet at this place the comfort of a ready-built house, but find rather a workshop full of restlessness and labour. In this sense, gentlemen, I beg you on your present visit, so heartily welcomed by us, to return to the city of Hamburg the sympathy which we old Hanseatic citizens and Lower Saxons cheerfully offer to our Anglo-Saxon cousins.

LAUNCHES AND TRIAL TRIPS.

Messrs. Fleming and Ferguson, shipbuilders and engineers, Paisley, have launched from their yard a powerful steel screw tug steamer, built to the order of the British Admiralty, being the last of four such vessels ordered by the Admiralty with this firm.

The steam yacht Kathleen, 316 tons, belonging to Earl Fitzwilliam, which has recently been fitted with new triple expansion machinery by Day, Summers, and Co., Southampton, went out for her trial trip on the 2nd instant, when the mean speed obtained on four runs at the measured mile in Stokes Bay was, we are informed, 11¾ knots. The diameters of the cylinders are 14in. 21½in., and 37in. by 24in. stroke, and the boiler is 11ft. diameter, by 9ft. 4in. long, the working pressure being 150 lb. The machinery is fitted into the same space as that occupied by the old machinery. The trial trip was in every way satisfactory, there being an entire absence of vibration which was much complained of with the old engines, the speed also being much greater.

The s.s. Jupiter left the port of Hartlepool for her trial trip a few days ago. The Jupiter has been built by Messrs. Wm. Gray and Co., for Messrs. Schmidt and Hansen, Flensburg, and is a steamer intended for the timber and general cargo trades, is built to Lloyd's highest class, and is of the following dimensions:—Length over all, 270ft.; breadth, 39ft.; depth, 18ft. 2in. She has been supplied with triple expansion engines from the Central Marine Engine Works of Wm. Gray and Co., the diameters of the cylinders being 19in., 30½in., and 51in., with a piston stroke of 36in., and steam is supplied by one large steel boiler working at a pressure of 160 lb. per square inch. The vessel had on board a cargo of pig iron and coal, and the trial which the ship and her machinery underwent was considered eminently satisfactory. The owners were represented by Mr. Harald Casper and Captain Hohlmann, the shipbuilders by Captain Murrell, the engine builders by Mr. G. H. Baines and Mr. Lindsay, and there were also present Mr. J. T. Sinclair, of West Hartlepool, and Mr. Lucas, of Darlington. On the completion of the trial the vessel at once proceeded on her voyage to Flensburg, under the command of Captain Hohlmann.

The steamer Lord Kelvin, which was recently launched by Messrs. Bartram and Co., of Sunderland, went on her trial trip on the 5th inst. The vessel is owned by Messrs. John Heron and Co., of Liverpool, and has been superintended during construction by Messrs. Flannery and Tritton, of Liverpool and London. She is of the following dimensions:—Length, 350ft.; breadth, 45ft.; depth, moulded, 26ft. 9in., with a carrying capacity of about 5200 tons on a very light draught of water. She is fitted with evaporator, freshwater condenser, feed-heater, and other modern steam fittings, all of which were tested under working conditions with satisfactory results. The main engines, which have been supplied by Messrs. John Dickenson and Sons, of Sunderland, have cylinders 24in., 39½in., and 65in., by 42in. stroke, and steam is supplied by two large single-ended boilers. The vessel was tried for several hours on the Tyne at full speed with most satisfactory results, the machinery working without the slightest hitch at seventy-eight revolutions, and steam being maintained with the greatest ease. Owing to the special arrangements devised with regard to the funnel and ventilation, the draught was unusually good, and the stokehold and engine-room very cool. The vessel was tried for several runs over the measured mile, and although her light draught, with propeller only partly immersed, made the conditions very unfavourable, she obtained a speed of upwards of 11½ knots. Her turning powers were also thoroughly tested, and proved her very handy. The owners and a large company of ladies and gentlemen were present.

On Saturday morning last, the fine steel screw steamer Simonside went on her trial trip. She has been built by Messrs. Wm. Gray and Co., to the order of Messrs. J. and E. Kish, of Sunderland. She takes Lloyd's highest class, and is of the following dimensions:—Length overall, 336ft.; breadth, 47ft.; depth, 24ft. 10in.; has a half poop, bridge over machinery space, topgallant forecastle, tasteful saloon and state rooms, together with captain and officers' rooms. The hull is built with web frames and double bottom under each hold for water ballast; there are six steam winches, steam steering gear amidships and screw gear aft, patent direct steam windlass, iron longitudinal grain division, and stockless anchors. The engines are of the triple expansion type, and have been supplied by the Central Marine Engine Works of Wm. Gray and Co. The cylinders are 24in., 38in., and 64in. diameter, with a piston stroke of 42in. There are three large main boilers of steel, working at a pressure of 160 lb. per square inch. This arrangement enables donkey boilers to be dispensed with, as any one of the main boilers can be kept under steam for working the winches, windlass, &c. A Mudd's evaporator and tail shaft preserver sleeve are supplied, and the vessel is otherwise fully equipped with all the appliances carried by a first-class cargo boat. The owners, Messrs. J. and E. Kish, were on board, as also their superintendent, Mr. M. Metcalfe—under whose superintendence the vessel and her machinery have been constructed; Captain Murrell represented the shipbuilders, and Mr. Jas. Lindsay the engine builders; there were also present Mr. C. L. Cummings, Mr. J. Wilson, Mr. H. Simpson, Capt. W. L. Sinclair—who is in command of the vessel—and Mrs. Sinclair, the Misses Forster, and Mr. John Tulley. The trial was a thoroughly satisfactory one, the engines running with great smoothness, the bearings keeping perfectly cool, and the boilers and glands quite steam-tight. Owing to the dense fog no speed trial was made. The vessel arrived at Sunderland at 8.30 p.m., where part of her company went on shore, the rest proceeding with the vessel to Barry Dock, where she loads for Port Said.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

There was a fair attendance on 'Change at Birmingham to-day—Thursday—and a satisfactory amount of business was done. The leading marked bar iron manufacturers report further inquiry, and recent quotations in that line are firmly maintained. A steady trade is moving in common bars at £5 5s. to £5 15s., and in merchant bars at £6 to £6 5s. There is a more pronounced demand for black sheets from the galvanisers, and prices are dearer by from 2s. 6d. to 5s. per ton more than last month's, £6 15s. being asked for doubles, and £7 15s. for trebles. Orders are offered to extend well into the next quarter, but manufacturers are reluctant to sell. Two new sheet mills have been erected and started at the Corrugated Iron Company's Stour Valley Works, Wolverhampton, which will increase the output by 100 tons weekly. The hoop and thin strip manufacturers report a fair amount of orders, and they are realising £6 7s. 6d. A steady volume of business is on the books for angles at £5 15s. Stamping sheets are £9 10s., and nailrod is £6 10s. Galvanised sheets are £10 5s. to £10 7s. 6d. for 24-gauge in Liverpool. In pig iron a moderate trade is being done, and prices are firm at £4 10s. for cold blast; 55s. for Staffordshire all-mine; 40s. to 42s. 6d. for part-mine; and 35s. for cinder. Northampton forge is 40s.; North Staffordshire and Derbyshire, 40s. to 41s.; and Lincolnshire, 43s. to 44s. The steel makers are actively engaged in executing last month's accumulated orders, and good lines are coming forward. Bessemer billets and blooms of Staffordshire make are £4 5s. to £4 7s. 6d.; Siemens billets are £4 10s. to £4 12s. 6d.; bars, £6; girders and angles, £5 12s. 6d.; and boiler-plates, £6 5s. The Association of Axlemakers has resolved, having regard to increased values of iron and activity of trade, to reduce discounts 2½ per cent. The Board of Trade returns for May show gratifying increases in the exports of iron and steel. Galvanised sheets in particular continue to occupy an excellent position in the market. Makers are full of orders, and prices are stiffening. The demand from the Colonies and foreign countries keeps up, and for the month of May the total reached the gratifying figure of 21,364 tons, as against 17,298 in May last year, and 14,222 in May, 1894. For May the percentage of increase on last year is 36·2, and for the five months it is 47 per cent., and other articles also show satisfactory increases.

The cycle and cycle-tube makers report continued activity of production, and the season's prospects are considered at least as good as they were a month or two ago, when the boom was at its height.

An interesting trial of the Kane-Pennington motor, an American invention, which the Humber Company, Coventry, have lately been using in the construction of self-propelled bicycles and tricycles, took place at Coventry this week. The trial took place on the Kenilworth-road, under the direction of Mr. Pennington, a Humber safety being fitted with the motor. In the matter of speed and facility of control the machine appeared to give perfectly satisfactory results.

It is of interest to the Birmingham marine engine building trades that H.M.S. Swordfish, the first of two of the new torpedo boat destroyers, built at Sir W. G. Armstrong, Mitchell, and Co.'s Elswick shipyard, and engined by G. E. Bellis and Co., of Birmingham, left the Tyne a day or two ago for Chatham, making the passage round the Nore in fourteen hours from Shields. This is, it is particularly noteworthy, the quickest passage on record, but, of course, well within the speed at which these vessels can travel. The sister vessel, Spitfire, together with the Swordfish, have, in fact, had satisfactory three hours' full-power runs off Tynemouth at a speed of 27½ knots, the machinery developing 4300 indicated horse-power. Both vessels are fitted with two sets of four-cylinder triple-expansion propelling machinery, with eight water-tube boilers, specified to develope under fan-forced draught 4000-horse power, and owing to the high speed at which the vessels have to be driven, the design has had to be very specially considered, to keep the weight within the maximum 110 tons. The shafting and working rods are hollow throughout, and the machinery at full power is run at the very high speed of 400 revolutions, or at a piston speed of 1200ft. per minute. The whole of the machinery and boilers, as well as the air compressors for torpedo work, the electric light plant, and other auxiliary machinery were built by Messrs. Belliss and Co., at their Birmingham works, and were fitted by their staff of Birmingham men on board the ships at Elswick shipyard. The machinery on the trials and passage round has been under the charge of the firm's marine superintending engineer, Mr. Thomas Scott, R.N. Messrs. Belliss have already completed four other ships of this class, built at Elswick and the Royal Dockyards. But I may mention that they are now so busy with electric light orders for central station and other installations that they have been obliged not only to extend their premises, but for the present at least to give up marine engine work almost entirely.

NOTES FROM LANCASHIRE

(*From our own Correspondents.*)

Manchester.—The ample supplies of both raw and manufactured material on the market, notwithstanding the general briskness throughout all consuming branches of industry, are making it evident that the existing means of production are fully sufficient to keep pace with any present prospective requirements. To this, no doubt, is due the check which has of late been given to the upward move in prices, whilst merchants and dealers are encouraged to underquote makers in the competition for orders, in the expectation that they will be able to squeeze down prices when they have to cover. The position, however continues very steady, with makers and manufacturers for the most part by no means over-anxious about new business just at present, orders in hand being, as a rule, still sufficient to keep them going, and there is a prevalent tone of confidence in the gradual improvement of trade.

The improvement in the iron market noticed last week has scarcely been fully maintained, and there was an absence of anything like general activity on the Manchester Exchange on Tuesday. For pig iron inquiries were only moderate, and although makers generally were firm at their late quotations, underselling still goes on amongst merchants, who frequently cut in very low to secure orders. For local brands of pig iron quotations are unchanged, and Lincolnshire and Derbyshire foundry qualities are also without quotable alteration; Derbyshire, however, continues weak, if anything. In forge Lincolnshire the partial advance of 6d. per ton, as I anticipated last week, has become general, 41s. net cash being now the all-round quotation delivered here. Middlesbrough and Scotch iron maintain late rates, but with makers in some cases putting into stock, the position is not altogether strong. Good foundry Middlesbrough averages 45s. 10d. to 46s. 4d. net delivered by rail Manchester, and 44s. Docks, with Eglinton about 46s. delivered Lancashire ports, and 48s. Dock Quays, Manchester, and Glengarnock obtainable about 9d. above these figures, although makers quote 49s. 9d. delivered ex stock Manchester, 48s. 6d. delivered Preston, and 47s. 6d. other Lancashire ports.

Although there is still low selling in the manufactured iron trade, chiefly in some of the commoner qualities of bars, which could be bought at £5 6s. 3d. to £5 7s. 6d., the position seems to be improving, and local branded irons are generally firm at £5 10s., with Staffordshire bars £5 10s. to £5 15s. Sheets are fetching rather better prices, £7 to £7 5s. being now the minimum, with hoops firm at £6 2s. 6d. for random to £6 7s. 6d. for special cut lengths, delivered Manchester district, with 2s. 6d. less for shipment.

In the steel trade only a moderate business is reported generally, but good foundry hematites are firm at 57s. 6d. to 58s., less 2½ delivered here. For manufactured material, however, prices are barely maintained at late rates, local-made steel bars being rather easier, if anything, the average selling prices being now about £5 17s. 6d. to £6, whilst ordinary local billets are obtainable at under £4 7s. 6d. net cash, with boiler-plates averaging £6 5s. per ton, delivered in the Manchester district.

In the metal market an active demand for all descriptions of manufactured goods continues the general report, the advance in prices which I reported last week not only being fully maintained, but the tendency is still in an upward direction.

Activity continues to prevail in all the iron-using industries, founders in many cases not having been so busy as they are now for several years past, whilst reports as to the condition of the engineering industry continue most satisfactory, and the employment returns of the trades unions show a continued tendency in the direction of a further decrease in the number of out-of-work members on the books.

At the closing sessional meeting of the Manchester Geological Society, held on Tuesday, Messrs. Holroyd and Barnes read a very interesting paper on the "Mountain Limestone Caverns at Tray Cliff Hill, Castleton, Derbyshire," in which they gave the results of their investigations with regard to the mineral deposits of the caverns, and of experiments they had made with a view of ascertaining the true origin of the varied colours found in the well-known Blue John spar, which is found in these mines. With regard to the origin of these minerals, the writers added that nothing in their researches, or in those of others had been put forward, that did not agree with the theory that both the metalliferous and mineral deposits were due to the action of waters derived from hot mineral springs, under suitable conditions of temperature and pressure. Of course there might have been other modes of formation, but the district contained all the conditions most favourable to deposition of the substances according to the above theory, viz., hot springs, the much-faulted ground, the nature of the country rock, and pressure of interbedded igneous rock, which had afforded additional metallic substances, and brought about in various ways most important changes. As to the conclusions which previous investigators had come to, that the varied colours of the Blue John spar were due to the presence of minute quantities of hydrocarbons, taken up from solutions, from which the mineral had been crystallised, the writers said that the chemists who had analysed fluor spar seemed to have confined their attention to the coloured varieties. If they had analysed the colourless variety, they would have found the same chemical constituents which were said to produce the colours. They, the writers, had made a number of experiments to find what substances were present in the spar, and determine the reason for its being coloured. They found that the dark fluor yielded ·12 per cent. of organic matter, and that the colourless fluor gave a similar amount, and these experiments thus showed that the organic matter present could not be the cause of the colour, as it was found both in the coloured and colourless fluor. The writers then asked themselves whether it was possible to produce, from pure material, fluor spar, and by synthesis, produce it coloured. If so, they would have proved beyond reasonable doubt that the colouring depended neither upon the iron and manganese present, nor upon the organic matter. They therefore endeavoured to synthesise the substance by taking pure calcium and hydrofluoric acid in excess and water, and after removing by evaporation the excess of acid, enclosing some of this white amorphous powder in a steel cylinder, and subjecting it to intense heat for many hours. On opening the cylinders, they found in practically every case crystalline fluor spar of various colours—green, yellow, rose, purple, and colourless. Eminent engineering authorities had given it as their opinion that the pressure inside the steel tubes was from six to eight thousand pounds per square inch. Given a sufficiently high temperature and pressure, they—the authors—believed that all substances, however refractory, might be made soluble in water, and on removal of the pressure, or on cooling, would crystallise out. From these experiments they deduced the fact that coloured fluor spar, whether naturally or artificially made, did not owe its colour to any special mineral ingredient or hydrocarbon, though these might be present, but rather to some peculiar molecular or physical state of the particles forming the crystals, or the crystalline mass, it was an optical phenomenon dependent upon crystallisation, and the physical state of the substance. This was borne out by the fact that pulverisation, which bruised the crystals, caused much of the colour to disappear, and that complete change of the physical state could be brought about by heating, as the particles decrepitated and lost their power of acting upon light. It was also found that if a coloured crystal was tapped gently on a solid angle of a cubical crystal, so as to induce a fracture parallel to the octohedron planes, the colour changed, and eventually disappeared. In a short discussion which followed, the point chiefly raised was with reference to the theory put forward as to the causes which produced the colour in the Blue John, some doubt being expressed as to whether the conclusions arrived at by Messrs. Holroyd and Barnes could be accepted as more than partially explaining the origin of these colours.

Business still drags on very slowly in the coal trade, the demand for all descriptions except engine fuel being extremely dull, and the absence of business coming forward is compelling colliery owners to limit their output, pits not now running on an average above four days per week. House coals meet with but a slow demand, and although prices are nominally unchanged, an easing tendency is noticeable. Steam and forge qualities continue very difficult to move, and for special sales extremely low figures are quoted, whilst the gas coal contracts continue to be competed for at under last year's rates. Engine classes of fuel, which are becoming less plentiful, are in good demand, with a hardening tendency, an advance of 3d. per ton being discussed, but as yet only actually quoted in very special cases. At the pit-mouth, best Wigan Arley averages 9s. 6d. to 10s.; Pemberton four-feet and seconds Arley, 8s. to 8s. 6d.; common house coal, 6s. 6d. to 7s.; steam and forge coals, 5s. 6d. to 6s.; common gas coal, 6s. 3d.; best sorts, 7s.; common slack, 3s. to 3s. 6d.; and best qualities, 4s. 6d. to 5s. per ton.

The shipping trade continues inactive, with prices low and unremunerative, and delivered Mersey ports 7s. is the full average figure for ordinary descriptions of steam coal.

Barrow.—There is an improvement to note in the demand for hematite pig iron, and makers are busier than they have been for some time past. They have only thirty-nine furnaces in blast, as compared with twenty-nine in the corresponding week of last year, but the output is a very large one, as the make per furnace now approximates 800 tons per week. Prices were up to 47s. 8d. on Tuesday, but on Wednesday they were down at 47s. 5½d. net cash sellers, 47s. 5d. net cash buyers. This depression was caused by speculative movements, and not by any shrinkage in the demand. Makers are quoting 49s. to 50s. per ton net f.o.b. for parcels of mixed Bessemer numbers. Stocks show a slight increase.

Iron ore is at its old price of 10s. per ton net at mines for ordinary sorts, and best descriptions are at 12s. 6d. to 14s. 6d., and there is a fair business doing in the latter. Spanish qualities are still largely used for mixing purposes at the West Coast furnaces, and the imports into Barrow and West Cumberland are steadily maintained. 60 per cent. descriptions are at the old rate of 12s. 6d. to 12s. 9d. per ton at West Coast ports.

Steel makers are well off for orders for plates and rails, and report a very good inquiry for forward delivery. Prices are very steady. There is a brisk trade doing in billets and hoops, but next to nothing doing in tin bars. This, however, is the only inactive department of the local steel trade.

Shipbuilders report no new orders, but tenders have been asked of the Barrow Company for the construction of a line-of-battle ship and one or more first-class cruisers. The preliminary steam trials of H.M.S. Powerful, first-class cruiser, have taken place at Barrow this week, with results giving the highest possible satisfaction. The port and the starboard engines were separately tested and both together at about quarter speed, and the Belleville boilers, of which there are forty-eight, were proved to be quick generators of steam. The Powerful is now ready for delivery to the Admiralty.

Coal is quiet, but coke is firm.

Shipments of pig iron from West Coast ports during the week have been 2735 tons and 3034 tons of steel, as compared with 5965 tons of pig iron and 4567 tons of steel in the corresponding week of last year, being a decrease of 3230 tons of pig iron and 1533 tons of steel. The aggregate shipments to date this year total up to 133,897 tons of pig iron and 200,608 tons of steel, as compared with 115,518 tons of pig iron and 157,194 tons of steel in the corresponding period of last year, an increase of 18,379 tons of pig iron and 43,414 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

IN the South Yorkshire coalfield four to five days a week are being made, with no perceptible change in the course of trade, except in regard to steam qualities, which are in brisker request. The coal requirements of London are at present abnormally small, judging by the tonnage sent from this locality, but it is believed that the sea-borne fuel is making the most of the market. Silkstone coal is now at 8s. to 8s. 3d. per ton for the best, while inferior sorts can be had from 7s. to 7s. 3d. In house coal, best Barnsley fetches from 7s. to 7s. 3d., thin seam coal being abundant at 6s. to 6s. 3d. per ton. Best South Yorkshire brands for shipment are in good demand, a number of the more important collieries sending freely to Hull. Last week the shipments of Yorkshire coal exceeded the business done in the corresponding periods of the last two years. Shipments are also well maintained at Grimsby, but Goole is taking a reduced tonnage. That port is chiefly supplied by the West Yorkshire pits. Railway companies are drawing supplies largely under their contracts, the Midland this season having placed a heavier weight than usual with the pits along their own line. In the open market prices of steam coal are from 7s. to 7s. 3d. for the best qualities, and 6s. to 6s. 6d. for secondary sorts. Manufacturing fuel continues to be in better demand, a large quantity going forward for coke-making purposes. Best screened slack makes from 3s. to 3s. 6d.; ordinary pit slack, 2s. 3d. to 2s. 6d.; smudge, 1s. 3d. to 1s. 6d. per ton, according to quantity ordered. In coke the output steadily increases, the pig iron trade being brisk in North Lincolnshire, while a fair tonnage is also taken by Derbyshire and Northamptonshire. Prices are from 8s. 6d. to 11s. for good smelting coke, best washed occasionally getting as high as 12s.

Apart from military material and several specialities, less animation is reported in the general run of the heavy industries, more particularly in railway and shipbuilding work. Manufacturers, however, have satisfactory orders on their books, and the lull will enable them to overtake any arrears caused by the holidays. Orders for armour for the additions to the naval programme are not yet forthcoming; foreign Powers are also much longer than was anticipated in placing their new work. Quotations:—Bessemer billets, £5 12s. 6d. to £6 per ton (special carbons); hematites, from 55s. to 57s. 6d., delivered in Sheffield; bar iron, £5 10s. at makers' works, £6 in warehouse; Lincolnshire forge iron, 39s.; Siemens-Martin acid steel, £7 10s. for average qualities.

Several Sheffield manufacturers who have just returned from the United States report business there to be more depressed than English people are aware of. Although he did not find that the Sheffield makes of high-graded steel, best cutting tools, &c., were being superseded by American or foreign production, yet there was no demand. In sheep shears for the River Plate the shipments are larger than usual; steel cutlery and edge tools are in fair request for Australia, and more is doing with the Brazils, the Argentine Republic, and Portugal.

Makers of agricultural machinery, whose business is largely in foreign countries are anticipating a better season in 1896-7 than the year which ended on the 31st of March last. The reports presented to public companies show that last season's harvest in many of the markets outside this kingdom was almost a complete failure, and greatly reduced the turn-over. Still, in spite of that drawback and the general complaints of extreme competition, the dividends have been well maintained, and in some instances a little more has been paid. It is remarkable that, with the increasing adoption of machinery, the demand for scythes, sickles, and the accessories of handwork in harvest getting, is greater than ever.

Mr. A. Bertram, for many years chief engineer at the Wigan Coal and Iron Company's Collieries, Wigan, has been appointed to a similar position at Messrs. Newton, Chambers, and Co.'s, Thorncliffe Collieries, near Sheffield. Before leaving Wigan, Mr. Bertram was entertained by the officials and workpeople at the Royal Hotel, Wigan, and presented with a cheque for £55, while Mrs. Bertram received a diamond ring.

The new Town Hall of Sheffield, which was to have been opened by the Queen last May, and is still waiting her Majesty's convenience, is now entirely completed, and partly occupied. The original estimate, as set before the Sheffield Corporation, was £80,000, but there have been so many additions and alterations, that the cost, including interest on sinking fund, is expected to exceed £250,000. The building, in its architectural features, has been already referred to in THE ENGINEER; now that it is finished the effect is both imposing and elegant. The Sheffield Electric Light and Power Company are working the installation. The public mains are tapped in Surrey-street, from which the electric current enters the transformers in a room in the basement, and is sent into the lamps at a reduced pressure of 100 volts. On each floor there are two points for the distribution and control of the current necessary for each side of the building. At the different points of distribution the lamps are divided into a large number of sub-circuits, in order that the current density in any of the circuits may not exceed 500 ampères per square inch of copper, and that all the lamps of similar candle-power may be of uniform brilliancy. Altogether about 1500 lamps, each of 16-candle power, will be fixed in the building.

The death is announced of Mr. Harry Wright Atkin, senior partner in the firm of Messrs. Atkin Brothers, silversmiths and electro-plate manufacturers, Truro Works, Matilda-street, Sheffield. Mr. Atkin, who resided at Norton Lees, Highgate, London, has for some time suffered from a weak heart, from which he died suddenly at the London office of the firm on the 2nd inst. The firm was established by the father of the deceased in 1824, and was conducted for nearly thirty years under the style of Henry Atkin and Co. In 1853 Mr. H. W. Atkin, with his two brothers, Mr. E. P. Atkin and Mr. F. S. Atkin, succeeded to the business, the name of the firm being then changed to Atkin Brothers. In the same year the works were transferred from Howard-street to Matilda-street. Mr. H. W. Atkin took charge of the London branch. Three of his sons are connected with the business, which is one of the best in the Sheffield silver and plating industry.

As this letter is closed, the Board of Trade returns for May come in. The two heads which chiefly concern Sheffield are "hardware and cutlery" and "steel unwrought." In the first the foreign business in May reached a value of £172,493, against £145,319 for May of 1895; the value for the five completed months of the year being £853,220, against £718,676 for the corresponding period of 1895. In steel, unwrought, the foreign trade reached a value in May of £233,503, against £147,366 for the corresponding month of 1895. In hardware and cutlery all markets show an increase, except Holland, Belgium, Foreign West Indies, and Argentine Republic. In steel, the only decreasing market is the United States, which took a value of £25,751, against £26,202 in May of last year.

Professor J. O. Arnold, of the Sheffield Technical School, has been awarded by the council of the Institute of Civil Engineers a Telford Medal and premium for his researches on "The Influence of Carbon on Iron."

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE iron market, though quieter than last week, has this week been fairly brisk, and on the whole must be described as in a satisfactory state. Some of the makers have sold considerable quantities of No. 3 for shipment, and have realised more than the generally quoted prices, as it is more likely that the prices will increase than decline. After the lull in business which was reported during May, consumers are beginning to buy more freely, and are showing a disposition to purchase for forward delivery, as they are not likely to gain anything by waiting. But producers do not care to sell forward, as prospects are in their favour. A very good feature of the market now is the excellent shipments of pig iron that are recorded from the Cleveland district. Usually June is a quiet month, and exports fall off; it was this year thought that they would be more likely to do so, seeing that the shipments during the past three months were the largest on record, and it was almost too much to hope that the briskness in deliveries would be maintained. However, the experience is that the exports are increasing; in fact, they much exceed those of each of the last three months, and if maintained will probably be the best on record. What is further noticeable, is that the deliveries are much more than maintained to the Continent, and it is to the Continent that they generally fall off in the summer months. There is, however, this year a tendency to buy more briskly, and this week one of the leading continental buyers of Cleveland pig iron —Mr. S. Elkan, of Hamburg—has been in this district. The exports of pig iron from the Cleveland district this month, up to Wednesday night, reached 49,993 tons, as compared with 35,164 tons in May, and 36,197 tons in June, 1895, to 10th.

The price of No. 3 Cleveland ordinary pig iron has been maintained both by makers and merchants at 37s. 6d. per ton for prompt f.o.b. deliveries, and nothing below that has been reported. Some producers have realised 38s. Merchants have sold for July-August delivery at 37s. 9d., but makers are not disposed to let their iron go at that. Cleveland warrants have kept about 37s. 5d. cash. No. 1 Cleveland pig, which is in fair request for the Continent, is firm at 38s. 9d., but No. 4 foundry and grey forge being more plentiful than for several months are easier in price; in fact, no difficulty is experienced in getting No. 4 foundry at 36s. 9d., and grey forge at 36s. 3d. Cleveland hematite pig iron is also easier in price, as the supply is in excess of the requirements. M. Nos. can be got at 45s. 9d. for prompt delivery, and a little less would not be refused by a good number of the producers. Cleveland hematite warrants are practically a drug on the market, and the nominal price is considerably below that obtained for makers' iron. Consumers do not care to buy Cleveland hematite warrants, for they do not know what brand will be supplied to them, and they may get one which will hardly suit their requirements. Accordingly they prefer to give a higher price, and secure the brand they need. The stock of Cleveland pig iron in Connal's public warrant stores is not increasing much this month, but that could hardly be expected with such heavy shipments. On Wednesday night the quantity held was 198,904 tons, or 454 tons increase this month.

The tendency in ore prices is to rise; in fact, Rubio ore has been put up 1½d. per ton this week, and is now quoted 12s. 9d. per ton, delivered at wharves on the Tees. The reasons for the advance are two-fold—in the first place, the rates of freight have been increased, as steamers are finding more employment in other and better paying directions; and, in the next place, there is a likelihood that the Spanish Government will put an export duty on iron ore, in order to help to provide funds to meet their expenses in Cuba. An export duty on ore has frequently been talked about and advocated in the Spanish journals, but now the time seems to be within measurable distance when a tax will be levied. Such a tax would increase the cost of hematite pig in this district, and would give the makers of basic pig iron and basic steel a better chance of competing than they have hitherto had. The Cleveland ironstone industry would likewise benefit by a curtailment of the imports of foreign iron ore.

The inquiry for finished iron and steel is rather quiet, but works in nearly all cases are well employed. Very large exports of rails, chairs, bridge work, and locomotives are being made from the Tees to India, Japan, and Australia. Some of the bridgework is from the Midlands. Some very large boilers, which have been constructed at Liège, have this week been put on board at Middlesbrough for Rio. We hear so much of British goods being forwarded to Hamburg and Antwerp in transit to the East that it is well to record a case of goods sent to this country in transit. The present quotation for heavy steel rails is £4 10s. net at works. Makers of steel railway sleepers complain of the falling off in demand, owing to many engineers going back to the old cast iron bowl chairs. Steel sleepers are quoted at £5 15s. per ton; cast iron bowl chairs, £3 5s.; and cast iron ordinary railway chairs, £2 17s. 6d., net at works. Steel ship-plates are at £5, less 2½ per cent. at works, and a fair demand is reported as shipbuilding is active. Some of the bar manufacturers have not been so well off for orders for many years, but they cannot advance prices, as others are not so fully occupied, and keep their quotations at the old figures. About £4 17s. 6d. per ton, less 2½ per cent. f.o.t., is now the rate for common iron bars. The steel mills are very well occupied, and particularly is the demand good for galvanised sheets, which are largely needed for export.

Pipe and chairfounders are more fully employed than for several years past, but have not been able to put up their prices much, because there is still plenty of room for improvement as regards the amount of work in hand. Engineers, particularly the locomotive and marine engineers, are doing well on the whole, and shipbuilders have a good deal more work on hand than at this time last year. Wire manufacturers have seldom been more fully occupied than at present, and the same may be said of wire rope manufacturers. Messrs. R. S. Newall and Sons, Washington, Durham, have started new rope-making plant at their works, and they claim that it is the largest cable-making plant in the world. They have in hand a cable for the Glasgow Subway Company, which will weigh 60 tons, and will be 33,600ft. in length and 4¾in. in circumference. It will be without a splice in any part of it. Cables up to 80 tons in weight can be made in one length by the new machinery.

The price of Durham coke has eased a little, as the supply is now larger than it has been for several months, and has at last more than overtaken the consumption, though the surplus is only small. Most consumers have already arranged their contracts for next quarters' requirements, and in some cases for the next half-year. There is now more coke being offered than has been known for nearly a year, and 13s. 6d. per ton delivered on Teesside will be accepted for average sorts. For steam coal the demand has considerably improved, shipments are brisk, and collieries producing this description of fuel are actively employed, this being the best time of the year for them. The price of best steam coal has been increased by some sellers to 8s. 6d. per ton f.o.b., but others will still accept 8s. 3d., and small steam coals are at 3s. 9d.

The Northumberland colliers are to vote by ballot whether their conciliation board is to be continued or to be abolished. It will be remembered that the Durham miners a short time ago voted for the abolition of their board. The shipments of coal from North-eastern ports last month amounted to 1,429,124 tons, or 71,451 tons less than in the corresponding month last year. A curious cause for a strike is reported at the Black Prince Colliery, Tow Law, the men refusing to work because a considerable number of the miners at that colliery are in arrears with their payments to the Union. The employers are thus made to suffer seriously through no fault of their own, but just because the men practically cannot agree among themselves.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market has shown a good deal of activity this week. The settlement of the wages question in the marine engineering trade, which had been the occasion of much uneasiness, has produced a very good effect, as has also the Board of Trade returns, which indicate that an increasing export business is being done in iron and steel manufactures. A large business has been done in Scotch warrants from 47s. to 46s. 10d. cash. Hematite warrants have been in greater request than for a considerable time past, and Cumberland iron has sold between 47s. 5½d. and 47s. 8½d. cash. Only a small inquiry has existed for Cleveland warrants, which have been done about 37s. 6d. cash.

The output of Scotch and hematite pig iron has been maintained at the highest point, there being 81 furnaces in blast compared with 76 at this time last year. There are 39 furnaces producing ordinary, 39 hematite, and three basic iron.

Stocks of pig iron are increasing in the public stores, which would seem to indicate that makers are turning out a surplus that cannot be fully absorbed at the moment. The addition to stock in Glasgow warrant stores in the past week has been upwards of 2000 tons, bringing up the total to 360,000 in round figures, against 282 at this time last year.

The shipping demand for Scotch pig iron continues on a moderate scale. The quantity cleared in the past week was 5210 tons, compared with 3692 in the same week of 1895. Of the total, there was despatched to Germany, 515 tons; United States, 350; India, 335; Canada, 70; South America, 20; Australia, 260; France, 184; Italy, 116; Russia, 200; Holland, 50; Belgium, 40; China and Japan, 170; other countries, 115; the coastwise shipments being 2785, against 1769 tons in the corresponding week. The total shipments, coastwise and abroad, from the beginning of the year to date, amount to 131,363 tons, compared with 137,336 in the same period of last year.

The prices of Scotch makers' pig iron are as follows:—Govan, Monkland, and Carnbroe, Nos. 1, 47s. 6d.; Nos. 3, 46s.; Clyde, No. 1, 49s. 6d.; No. 3, 46s. 6d.; Gartsherrie, Calder, and Summerlee, Nos. 1, 50s.; Nos. 3, 47s. 9d.; Coltness, No. 1, 52s. 6d.; No. 3, 48s.; Glengarnock at Ardrossan, No. 1, 50s.; No. 3, 45s. 6d.; Eglinton, No. 1, 47s.; No. 3, 45s.; Dalmellington at Ayr, No. 1, 46s. 6d.; No. 3, 44s. 6d.; Shotts at Leith, No. 1, 52s.; No. 3, 48s. 6d.; Carron at Grangemouth, No. 1, 52s. 6d.; No. 3, 48s. 6d.

Makers' of finished iron report that business is keeping up very well; indeed, this branch appears to be in a better position than for a considerable time past. A feeling had been growing for years that malleable iron was doomed to be superseded by steel, but this apprehension seems now to be falsified, for there is a substantial revival in the demand for malleable iron, and that, too, at the very time that steel is likewise very active.

The position of the coal trade is rather disappointing, the past week's shipments from Scottish ports have amounted to 143,387 tons, compared with 152,779 in the preceding week, and 148,289 in the corresponding week of last year. The reduction in the shipment is in part due to a scarcity of handy steamers; shippers to the Mediterranean, for example, are reported to have had, within the last few days, orders in hand which they could have executed if suitable tonnage had been available. For main, splint, and steam coals the demand is quiet. Furnace coal and dross, and the better qualities of household coals are in active request. The municipalities and gas companies are now purchasing considerable quantities of cannel and splint coals. Prices f.o.b. at Glasgow are, for main coal, 5s. 9d.; splint, 6s. 3d. to 6s. 6d.; ell, 6s. 3d. to 6s. 9d.; steam, 7s. 6d. per ton.

The question of the wages of the operative engineers in the marine engineering trade of the Clyde and Belfast has now fortunately been arranged. The employers offered an advance of ¼d. per hour, advance to hold good for six months, taking effect from the middle of the present month, and the workmen have accepted these terms by a vote showing a considerable majority.

Several good shipbuilding contracts have been received by Clyde builders, in addition to those noted last week.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

A FAIR amount of business was done last week at the iron and steel works, and I am glad to see that, not only has there been a substantial increase in steel bar orders, but tolerably good ones for steel rails are in hand. The report on 'Change, Swansea, this week, was to the effect that there was an increased demand for finished iron and steel, but more particularly for the latter; that the demand for rails in that district continued brisk, and that rail makers will be fully employed for months to come; and that for steel bars there was a pressure for immediate delivery.

At the close of last week an important cargo of steel rails, 1400 tons, went to Singapore and Hong Kong from Cardiff. This week one cargo of 370 tons rails went to London from Newport, and a small one of 118 tons for Highbridge from the same port.

The leading ironmasters have been getting in large stocks of ore this week from Elba, Castro, Garucha, and Bilbao. Blaenavon was specially noticeable for one cargo of 3900 tons, and another of 1850 tons, Ebbw Vale one of 1600, and three important cargoes for Dowlais. Another large shipment of pig iron from Bilbao came into Newport this week, while Scotland, Barrow, and Whitehaven have been busy importing pig iron to Swansea. In all 570 tons came by sea to Swansea last week, also another cargo of sulphide ore, 2562 tons, consigned from Port Pirie.

There is a gratifying improvement in tin-plate, but makers, whose mills are now working briskly, are afraid that it is of but a temporary character, as such a large number of mills are idle, and there will be a great likelihood that the news of improvement will prompt tin-plate manufacturers to start and bring about by over-production a repetition of the old state of things. Still it will be well not to get unreasonably apprehensive. The "turn" may be at hand, and if increased demand should set in, well and good. I see that last week the shipments of tin-plates amounted to 90,928 boxes, while make was only 68,454 boxes. Stocks at Swansea are now down to 164,056 boxes.

Statistics to hand are encouraging, as showing a greater variety of customers for Welsh plates, the falling off to the States being partially made up by increased shipment elsewhere. Some countries have exceeded their former requirements by 83 per cent. Taking the totals for May, 1895 and 1896, I find that the shipment to Germany last month was 1432 tons against 491 for May, 1895; France, 995 tons against 784 tons; Portugal, 669 against 284; Italy, 894 against 538; Austria, 211 against 90; Straits Settlements, 1111 against nil. Canada showed a decline—142 tons against 765 tons.

An improved trade in spelter is announced, an indication that the make of galvanised sheets is on the increase.

Prospects at Pyle are improving, and increased briskness is likely. Large quantities of ferro-manganese used to be sent from this quarter.

Iron and steel quotations, Exchange, Swansea, mid-week, were as follows:—Glasgow pig, 46s. 10½d. cash; Middlesbrough, No. 3, 37s. 6½d., hematite, 47s. 5d.; Welsh bars, £5 10s. to £5 12s. 6d.; iron plates, £6 to £6 17s. 6d. Steel, £6 to £6 17s. 6d.; steel rails, heavy sections, £4 10s. to £4 12s. 6d.; light, £5 10s. to £5 15s. Bessemer steel, tin-plate bars, £3 17s. 6d.; Siemens, best, £3 18s. Tin-plates, Bessemer steel cokes, 9s. 3d. to 9s. 4½d.; Siemens coke finish, 9s. 6d. to 10s.; ternes, per double box, 28 by 20c., 16s. 6d., 17s. 6d., to 21s.; best charcoal, 12s. 9d. to 13s.; wasters, 6d. to 1s. per box less, all delivered Prince of Wales' Dock, Swansea, cash less 3 and 1 per cent.

The coal shipments last week again showed the result of holidays, the total from the Cardiff ports being about 285,000 only, and until the 300,000 tons are again exceeded the inference must be that the old state of make has not been regained.

I note, however, this week that the demand for best is improving, and the long list of large tonnages on several days is a promise of better things.

Mid-week good seconds were inquired for freely, but drys and Monmouthshire coals were not selling well. Small steam is getting a trifle more brisk. House coal continues sluggish, and some of the minor coalowners look forward somewhat gloomily to the summer months ahead.

Swansea coal shipments last week were satisfactory, slightly exceeding late averages. Newport total foreign was 37,515 tons; coastwise, 19,453 tons. From Briton Ferry some large cargoes of coal and coke have been despatched. I see that at Porthcawl the coal trade has been fairly brisk. Engineers have been surveying the dock of the Great Western Railway Company at this place, with a view to carry out extensive repairs of gates and piers. The estimates are now under consideration. This carried out, and the Esplanade put into good order, would materially benefit one of the best seaside resorts of the Glamorgan coast.

At Cardiff there is an unabated demand for coke, and shipments continue large. Patent fuel is also in moderate demand at Cardiff and Swansea.

Cardiff quotations mid-week, on 'Change, were as follows:—Best steam, 10s. 3d. to 10s. 6d.; special seconds, 9s. 9d. to 10s.; ordinary seconds, 9s. 3d. to 9s. 6d.; drys, 8s. 7½d. to 9s.; best Monmouthshire, 8s. 3d. to 8s. 6d.; seconds, 7s. 9d. to 8s.; best small, 4s. 9d. to 5s.; seconds, 4s. to 4s. 6d.; drys, 3s. 6d.; best house, 9s. 6d. to 10s.; No. 3 Rhondda, 9s. 6d. to 9s. 7½d.; brush, 7s. 6d. to 7s. 9d.; small, 6s. 3d. to 6s. 6d.; No. 2 Rhondda, 7s, to 7s. 3d.; through, 6s. to 6s. 3d.; small, 4s. to 4s. 3d.

Swansea quotations:—Anthracite, best, 11s. to 11s. 3d.; seconds, 9s. to 10s.; steam, 9s. to 10s.; seconds, 8s. 3d. to 9s.; No. 3 Rhondda, 9s. to 10s.; No. 2, 8s. 6d. to 9s. 6d. Cardiff quotations: —Coke, furnace, 12s. 9d. to 13s. 9d.; foundry, 15s. 6d. to 16s. 9d.; special, 19s. 6d. to 19s. 9d. Pitwood, 16s.; quieter, more cargoes coming in. Swansea patent fuel, 9s. 9d. to 10s. 3d.

A quantity of colliery plant, machinery, &c., is to be dispersed this week at Penrhiwfer, one of the collieries of the Glamorgan Coal Company in the Rhondda, and next week a compact tin-plate works at Aberavon, known as the Japanese Works.

Amongst the leading subjects of discussion in the district is the rumoured amalgamation between the Taff Vale Railway and the Rhondda and Swansea Bay Railway. Sir John Jones Jenkins, approached on the matter by the representative of a Swansea contemporary, expressed his opinion that it would be a good thing, particularly for the Taff Vale, if the amalgamation came off.

Wales is again excited by the recommendation of the Water Committee of the London Council to go forward in the matter of a supplementary supply from the Welsh watersheds. The end of the drought of sixty days has brought about a lessened friction between town surveyors and urban Boards as to the condition of local water supplies; and if the engineering work now going on in various localities be brought to a head by next spring, I do not think that the protest of Welsh members in the House against the London scheme will be so severe as anticipated. If Wales were to be afflicted with a great drought during the water campaign in the House, the Rebecca, Tithes, and Chartist days would have the addition of another formidable agitation.

The new coal charter continues to form a topic of discussion on 'Change, Cardiff. At a special meeting of the Cardiff Shipowners' Association on Monday, the secretary was instructed to write to the local dock companies, stating that by the terms of the new coal charter, which comes into operation on the 1st July next, the wharfage on cargo hitherto paid by the shipowner will be paid by the charter.

The viaduct on the Great Western Railway at Cardiff was opened for traffic this week, and forms an excellent improvement, obviating a great deal of waiting and delay outside the station.

The "6ft." seam of coal has been struck at Morfa, Port Talbot, causing much rejoicing.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

THERE is not much of special interest to be reported this week, the raw and finished iron departments being, without exception, in a healthy, active condition.

It is gratifying to note the lively business on the Silesian iron market, which has been steadily improving from week to week, and is now in a state of general briskness, such as has not been known for a long time. As the employment of the manufactured iron and steel works is sure to increase as the year advances, a very strong demand continues to come forward in the pig iron trade, and for orders for the first quarter of 1897, which here and there have been booked, purchasers willingly pay higher prices.

Prospects for further satisfactory occupation in the manufactured iron industry are very good. Besides being actively engaged in the production of girders and bars, the mills also report an uncommonly brisk demand to be coming forward for plates and sheets; the tendency of prices naturally continues to be in an upward direction.

The favourable condition of the Russian iron market is having a good influence on the Silesian export trade, the orders received from Russia being, as a rule, heavy. Projected enterprises in railway plant and mining developments will help to secure a good employment to the engineering industries.

The iron market in Austria-Hungary continues to exhibit a tendency to improve. Stocks are very low, consumption being almost equal to production. Official quotations are the same as previously reported.

French iron business shows considerable animation, and a very firm tone with regard to prices prevails. In Paris merchant iron is exceedingly scarce, which may partly be due to the exceptionally mild winter and to the consequently early revival in the building trade. In the Maas and Moselle district a very considerable decrease in stocks has taken place, and prices are very much inclined to rise; since the beginning of the year an advance of 4f. p.t. has taken place.

Belgian iron business has been just a trifle more quiet during the week that is now past, only few and rather small contracts having been placed. However, there is still a healthy activity noticeable in the different departments, which will probably continue until a fresh amount of work is secured. Prices are firm. The Belgian coal trade is very steady, and slight advances in quotations have even been ventured. At a recent tendering for 400,000 t. locomotive coal for the Belgian State Railways the collieries have well maintained the lately enhanced prices.

Orders for both raw and manufactured iron continue to come in satisfactorily on the Rhenish-Westphalian iron market, and nearly all the works are consequently in brisk employment. Iron ore has met with a decided improvement; the Siegerland mines are hardly able to produce the quantities required, spathose iron ore having, perhaps, never before been so briskly inquired for as it is now. Prices are, for spathose iron ore, M. 9 to 9·60 p.t.; roasted ditto, M. 12 to 13 p.t.; calcined iron ore, M. 12 to 14 p.t. at mines. In Nassau the trade in iron ore is less lively, but may still be regarded as fairly satisfactory, the 50 p.c. red iron ore being sold at M. 9·60 to 9·80 p.t. Lorraine minette is quoted M. 2·40 to 2·60 p.t.; the 40 p.c. sort fetching M. 3·20 p.t. net at mines.

The pig iron market is very active, and stocks are small. Last week's quotations were:—Spiegeleisen, 10 to 12 p.c. grade, M. 50; forge pig, No. 1, M. 53 to 55; No. 3, M. 42; hematite, M. 65; foundry pig, No. 1, M. 65; No. 3, M. 57; basic, M. 56; iron for making steel, M. 54 to 56 per ton at works. Luxemburg forge pig is quoted 56f. p.t. free Luxemburg. The physiognomy of the malleable iron business continues bright. Makers have well filled their order books, and are rather indifferent about selling largely at present. Prices remain exceedingly firm, but leave very little profit generally. However, so long as the raw materials do not further advance, manufacturers are fairly well satisfied with the present state of things, feeling sure that a rise in quotations will take place ere many weeks have passed. Bars remain in strong request, both on home and on foreign account. The same may be told of girders. The hoop mills are well employed, and have raised the basis price. Rivets are in good call, comparatively speaking, and prices show a stiffening tendency.

The following are the present list quotations, per ton at works: Good merchant bars, M. 120 to 122; angles, M. 130; girders, M. 94 to 97; hoops, M. 125; billets in basic and Bessemer, M. 85 to 86; heavy plates, for boiler-making purposes, M. 160 to 165; tank plates, M. 135 to 140; steel plates, first quality, M. 145; second quality, M. 130; tank plates, in steel, M. 120 to 125; sheets, M. 137 to 150, in some instances, M. 155; iron wire rods, common quality, M. 130; drawn wire, in iron or steel, M. 118 to 138; wire nails, M. 127 to 130; rivets, good qualities, M. 185 to 190; complete sets of wheels and axles, M. 280 to 290; axles, M. 220; steel tires, M. 200; steel rails, M. 118; steel sleepers, M. 110; fish-plates, M. 120 to 130; light section rails, M. 100.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

THE demand for steam coal keeps fairly good, with prices unchanged. House coal shipments are quiet; prices same as last week. Tin-plates continue in demand, with prices very firm. The iron and steel works are all well employed. Fairly good attendance.

Coal: Best steam, 8s. 3d. to 8s. 6d.; seconds, 7s. 9d. to 8s.; house coal, best, 9s. 9d. to 10s.; dock screenings, 5s. to 5s. 3d.; colliery small, 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 46s. 9½d.; hematite warrants, 47s. 5d. f.o.b. Cumberland; Middlesbrough, No. 3, 37s. 5d. prompt; Middlesbrough hematite, 44s. 10d. Iron ore: Rubio, 12s.; Tafna, 11s. 3d. Steel: Rails, heavy sections, £4 12s. 6d.; light ditto, £5 f.o.b.; Bessemer steel tin-plate bars, £4. Siemens' tin-plate bars, best, £4 2s. 6d.; all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel, coke, 9s. 3d.; Siemens, coke finish, 9s. 6d.; ternes, per double box, 28 by 20 C, 19s. to 20s. 6d. Pitwood: 16s. to 16s. 3d. London Exchange Telegram: Copper, £47 13s. 9d.; Straits tin, £60. Freights firm.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, June 4th.

MANUFACTURERS are more deeply concerned with business politics this month than with quotations, feeling the latter will take care of themselves, if political measures are right. It is virtually settled that the money power in the United States has been propitiated by private assurances, which satisfies it that it will own the next president, hence the almost death-like silence in the gold journals. The masses of the people have no suspicion that they are to be sold out, but it is all fixed, and Britain's millions can start on their crusading investment in "Americans" as soon as they feel like starting. The iron trade is very dull, for two or three reasons: first, people are waiting to see what way the St. Louis cat will jump. It will be into the gold bag with a sympathetic purr, for silver buyers of steel will not place their big contracts much before July. It would be no more than guesswork to say now what volume of business will probably be placed in July, or what such action will have on prices. It is known that quite a number of large iron and steel consumers have already been assured of supplies at fixed prices, and it is presumable that these people will not be in as great haste as others on the first appearance of the better conditions which almost all are anticipating for the latter half of the year. The actual consumption of iron and steel is heavy, probably on a basis of 170,000 tons per year. When the urgent work projected for this year is entered upon, these figures will be exceeded. There is some movement among railroad managers for rolling stock, which may develope into a considerable demand by August. Earnings improve slowly. Prices are low, but this fact augurs well. Buyers frequently go like sheep when something occurs to start the first one, and that is the next thing in order.

11,538. Treatment of Seaweed, A. Krefting, London.
11,539. Elastic Wheel Tires, E. E. Duller, London.
11,540. Steering Gear for Velocipedes, J. Monteith, London.
11,541. Trees for Boots, H. W. Mobbs and A. Lewis, London.
11,542. Pneumatic Tires for Cycles, L. T. Darnault, London.
11,543 Axles, J. R. Quain and F. W. Dunlap, London.
11,544. Binocular Hand Glasses, E. Bloch, London.
11,545. Means of Advertising, F. J. Watts and F. Poston, Ilford.
11,546. Construction of Gas Engines, J. G. Horsey, London.
11,547. Umbrella Frames, W. P. Thompson.—(*L. E. Bisson, France.*)
11,548. Spark Arrestors, W. P. Thompson.—(*F. E. H. W. Krichauff, Australia.*)
11,549. Devices for Gas Engines, A. A. Hamerschlag, London.
11,550. Applliance for Ladies' Skirt, R. J. Edward and R. Hall, Liverpool.
11,551. Cycle Handles, J. G. Dobson.—(*H. H. Johnson, United States.*)
11,552. Means for Switching Current, C. Adam, Liverpool.
11,553. Production of Filaments, &c., J. W. Swan, London.
11,554. Velocipedes, S. Frank, London.
11,555. Manufacture of Sulphide, D. A. Peniakoff, London.
11,556. Saddles Suitable for Cycles, F. M. Gilmore, London.
11,557. Producing Gaseous Mixtures, S. Pitt.—(*The Société Anonyme de l'Institut Raoul, Pictet, Switzerland.*)
11,558. Machines and Motor Cycles, A. Williams, London.
11,559. Water-softening Apparatus, H. L. Doulton and A. W. Manger, London.
11,560. Hydraulic Forging Presses, C. Davy, London.
11,561. Rifle Bullets, A. Reinhard.—(*A. Krupp, Austria.*)
11,562. Nut-locking Devices, W. Wright, London.
11,563. Toys, W. Tyree, London.
11,564. Distributing Pulverulent Material, C. Oesterheld, London.
11,565. Excluding Dust from Bearings, C. A. Drake, London.
11,566. Globes, W. H. Gritton, W. Edwards and H. B. Sheridan, London.
11,567. Saddles, O. von Briesen, London.
11,568. Tobacco Pipes, H. J. Bird, London.
11,569. Resilient Soles for Boots, J. R. Gumley, London.
11,570. Boxes for Storage of Papers, W. Willig, London.
11,571. Means for Advertising, R. D. G. Hall, London.
11,572. Boxes, W. H. Scott and W. M. Turner, London.
11,573. Automotive Vehicles, R. Haddan.—(*F. de Couinck, France.*)
11,574. Skein Holders and Winders, H. Brocklebank, London.
11,575. Toys, W. L. Urquhart, London.
11,576. Reflecting Light from Candles, L. Silberstein, London.
11,577. Constructing Marine Vessels, E. L. Kitchingham, London.
11,578. Double-faced Automatic Machines, L. Silberstein, London.
11,579. Fastener for Envelopes, J. W. Wilkins, London.
11,580. Manufacturing Nuts, J. H. Sternbergh, London.
11,581. Gas Lighting, G. Moreau and A. Poulhiès, London.
11,582. Apparatus for Pearl Fishing, E. Veron, London.

28th May, 1896.

11,583. Stop-cock for Hose Branches, W. Hanlon, Cork.
11,584. Machines for Filling Bottles, A. P. Blaxter, sen., London.
11,585, Cycle Seats or Saddles, T. W. Woodgate, London.
11,586. Metal Liquid Polish for Brass, C. D. Scott, Birkenhead.
11,587. Locomotive or Motor Vehicles, E. K. Dutton, Harrogate.
11,588. Air Pumps for Pneumatic Cycles, H. D. Simpson, Derby.
11,589. Chair Backs, &c., P. J. Job and P. B. H. Seabrook, London.
11,590. Attaching Golf Club Shaft to Head, G. Young and J. Anderson, Glasgow.
11,591. Oil Lamp Burners, A. H. Griffiths and T. B. Smith, Birmingham.
11,592. Pulleys for Hauling and Winding, T. Bodycombe, Bristol.
11,593. Gulleys, A. T. Swain, Manchester.
11,594. Window Tickets, J. Parkinson, Keighley.
11,595. Covers for Cycle Tires, D. Nelson and A. Tayler, Glasgow.
11,596. Leather Cleaning Apparatus, J. W. Blakey, Leeds.
11,597. Adjustable Spanners, J. R. Cooper, Birmingham.
11,598. Elastic Tires for Vehicle Wheels, J. P. Roe, London.
11,599. Mixing Liquids and Solutions, G. T. Gillespy, Manchester.
11,600. Cycle Frames, J. McElroy and R. McMillan, Belfast.
11,601. Harness, A. Black, Edinburgh.
11,602. Gas Meters, Bruxelles, sen., Brussels.
11,603. Piano Keyboard Guide, F. Gunther, Brussels.
11,604. Transforming Negatives, &c., M. Magnus, Brussels.
11,605. Purses, Bags, Pocket Books, E. G. Johnson, London.
11,606. Lamp and Heating Device, J. D. Humphrey, London.
11,607. Boots, A. M. Boilinger, London.
11,608. Sheet Metal Rolling Mill, J. Matthews and A. G. Sherman, London.
11,609. Frames for Grindstones, S. C. Schofield, London.
11,610. Velocipedes, A. J. Murphy. London.
11,611. Cuff Holders, N. L. Reynolds, London.
11,612. Moulding and Fret Cutter, J. Delli, London.
11,613. Opening Out Vegetable Fibres, A. R. Waddell, Airdrie.
11,614. Automatic Tipping Apparatus, R. M. Howatt, London.
11,615. Safety Clip for Lift Ropes, G. Q. Roberts, London.
11,616. Pneumatic Springs for Vehicles, F. J. Esmond, London.
11,617. Electric Alarm for Railway Trains, H. Binko, London.
11,618. Hook and Eye, D. Joy, Kent.
11,619. Fluid for Cleaning, &c., Paint, J. Cornwall, London.
11,620. Small-arms, T. Perkes, London.
11,621. Effecting the Separation of Gases, H. Maxim, London.
11,622. Duplex Gripper Pneumatic Tire, G. E. Brinkworth, London.
11,623. Writing and Drawing Pencil, K. Gengnagel, St. Leonards-on-Sea.
11,624. Appliance to be Attached to Bicycles, T. P. Chittenden, London.
11,625. Tires of Cycles, J. James, sen., and J. James, jun., London.
11,626. Pneumatic Wheel Tires, W. E. Rowlands, London.
11,627. Secondary Batteries, E. J. Clubbe, A. W. Southey, and The Electric Motive Power Company, London.
11,628. Buttons, N. Hipwell, London.
11,629. Toy, W. P. Thompson.—(*E. Reuther, Germany.*)
11,630. Biscuit Boxes, G. A. Foster, London.
11,631. Lasting Machines, H. von Kalinowski, London.
11,632. Water Gas, J. E. Goldschmid and C. Dellwik, London.
11,633. Filtering Apparatus, S. K. Welch, London.
11,634. Elastic Tires, C. Fox, London.
11,635. Brake Mechanism for Bicycles, &c., P. E. Doolittle, London.
11,636. Oil Lamps, J. F. C. Jürgens and A. B. Kistritz, London.
11,637. Apparatus for Preserving Milk, A. J. Vause, London.
11,638. Bicycle Supports, P. A. Newton.—(*J. J. Slevin, United States.*)
11,639. Exhibiting Phases of Movement, J. N. Maskelyne, jun., London.
11,640. Optical Instruments, J. Richard, London.
11,641. Files for Letters, F. W. Marriott, London.
11,642. Game Scorers, T. F. Barber, London.
11,643. Parcel-carrying Apparatus, J. Smith.—(*N. Guthridge, Australia.*)
11,644. Brake Pipe Couplings, J. E. Bousfield.—(*M. L. Weaver and B. B. Babcock, United States.*)
11,645. Mattresses, F. W. Golby.—(*O. Steiner, Germany.*)
11,646. Mechanical Musical Instruments, F. W. Golby.—(*U. Schwerin and Co., Germany.*)
11,647. Electric Couplings. E. Theodora, London.
11.648. Braking Road Vehicles, D. Cremmen, London.
11,649. Frames for Cycles, B. Verity and T. Stoward, London.
11,650. Wheels for Railway Wagons, &c., F. Ludewig, London.
11,651. Cutting Glass, A. J. Boult.—(*B. Gruhl, Germany.*)
11,652. Letters or Characters, W. R. Lake.—(*G. J. B. Rodwell, United States.*)
11,653. Material for Packing Articles, J. N. Beach, London.
11,654. Pneumatic Tires, O. Jones, London.
11,655. Engine Indicators, F. Grover and G. A. Mower, London.
11,656. Engines and Motors, F. Lamplough and F. T. Goodman, London.
11,657. Pneumatic Tube Valves, J. P. Hitchcock and J. Dring, London.
11,658. Keels of Sailing Vessels, C. A. Jensen.—(*C. Stangeby, Norway.*)
11,659. Pneumatic Tires for Cycles, V. de H. Dowler, London.
11,660. Variable Speed Gear for Cycles, D. Joy, London.
11,661. Fixing Music and Reading Desks, J. H. Rosoman, London.
11,662. Corkscrews, R. A. Brown, London.
11,663. Harness Hangers, C. E. Barber.—(*The Gleason and Bailey Manufacturing Co., United States.*)
11,664. Ore Separating Apparatus, W. T. Newman, London.
11,665. Tea and Coffee Cups, &c., H. C. Parsons, London.
11,666. Pneumatic Tire Covers, A. H. Culley, London.
11,667. The Union Stopper, G. A. Leighton and C. Ball, London.

29th May, 1896.

11,668. Small Arms, R. P. Puelma, London.
11,669. Saddle Pins for Cycles, J. Womack, Doncaster.
11,670. Vessels for Containing Liquids, R. J. Parkes, Liverpool.
11,671. Supporting the Frames of Cycles, R. J. Parkes, Liverpool.
11,672. Wheel Tires, W. Hughes, Birmingham.
11,673. Marking Emery Cloth, W. M. Fuller and F. G. Williams, Birmingham.
11,674. Carpets, The Heckmondwike Manufacturing Co. and W. Holt, Halifax.
11,675. Wheels for Cycles, Auto Cars, &c., E. Wright, London.
11,676. Wheels for Cycles, J. W. Laing, Glasgow.
11,677. Raising and Lowering Cages, M. J. Oliver, St. Tudy, Cornwall.
11,678. Springs for Use in Cycles, &c., D. Doyle, Youghal.
11,679. Boot Tree or Last, W. Bourne, Ashton-on-Mersey.
11,680. Shaping Metal Tubes, W. T. Smith, Keighley.
11,681. Hubs for the Wheels of Cycles, R. F. Hall, Birmingham.
11,682. Manufacture of Silica Bricks, J. Dixon and A. Reynolds, Sheffield.
11,683. Safety Flush Bolt for Doors, A. Wache, Berlin.
11,684. Paper Feeding on Double Action Machines, A. Hellman, Berlin.
11,685. Velocipedes, J. E. Evered and D. G. Pappa, London.
11,686. Cycle, &c., Route Indicator, H. C. Hope, London.
11,687. Pneumatic Tires, H. J. Heinze, London.
11,688. Pneumatic Tires, H. J. Heinze, London.
11,689. Door Lock Furniture, H. D. Hodgkinson and R. A. Hall, London.
11,690. Opening Sealed Cans, R. A. Sloan and J. E. L. Barnes, Liverpool.
11,691. Pneumatic Tires for Cycles, E. C. Ogden, London.
11,692. Uniform Pressure in Gases, &c., F. Doller, London.
11,693. Burning Vapourised Petroleum, H W. Hatfield, London.
11,694. Drawing Down Machines, A. C. Wright, London.
11,695. Hardening Chrome Leather, K. Möller, London.
11,696. Coin-freed Gas Meters, R. T. and J. G. Glover, London.
11,697. Typewriters, J. Melling, Kent.
11,698. Soldering Appliances, G. B. Harkes and C. E. Bacon, London.
11,699. Pneumatic Tires, A. F. Aldridge and T. Hewett, London.
11,700. Toy, R. Wallwork, London.
11,701. Polishing Steel, G. Hales, C. Tutill, and C. Greensides, London.
11,702. Medicine for Curing Lumbago, C. Canham, London.
11,703. Stern Tubes of Steam Ships, D. C. F. Wulff, Sheffield.
11,704. Constructing Steam Generators, M. Le Blant, London.
11,705. Elastic Tires for Vehicle Wheels, J. P. Roe, London.
11,706. Purifying Acetylene Gas, E. F. J. C. Bauweraerts, London.
11,707. Burner for Acetylene Gas, E. F. J. C. Bauweraerts, London.
11,708. Generation of Acetylene Gas, E. F. J. C. Bauweraerts, London.
11,709. Pneumatic Duplex Teats, A. E. Booth, London.
11,710. Joining Metallic Tubes, W. L. Poole, A. tone, A. St. V. Turquand, London.
11,711. Threshing Machines, F. Korb, London.
11,712. Frames of Velocipedes, J. Mason, London.
11,713. Generator for Road Carriages, P. Davies, London.
11,714. Receptacles for Holding Papers, G. Blakey London.
11,715. Bicycles, S. A. Watkins and W. A. D. Keys, London.
11,716. Fertiliser and Insecticide, F. E. Rutland, London.
11,717. Covering Steel Plates with Copper Sheeting, W. T. Lougher, Swansea.
11,718. Basic Lining for Pig Iron, O. Imray.—(*Oberschlesische Eisenbahn-Bedarfs Actien Gesellschaft, Germany.*)
11,719. Attaching Pneumatic Tires to Wheels, C. Merington, London.
11,720. Lock Stitch Sewing Machines, A. E. Duncan, London.
11,721. Corsets, H. Bendy, London.
11,722. Cycles, S. A. Watkins and W. A. D. Keys, London.
11,723. Pneumatic Tires for Cycles, H. N. Grove, London.
11,724. Electrical Hot Plates, A. E. Woodhouse, London.
11,725. Gear Wheels, R. O. Cowan, London.
11,726. Pneumatic Tires, W. Corah, jun., London.
11,727. Cycles, W. A. Aikin, London.
11,728. Cycles, W. F. Hills, London.
11,729. Nutlocks, W. P. Thompson.—(*J. Schirra, United States.*)
11,730. Producing Galvanic Depositions, W. P. Thompson.—(*The Elekta Galvanoplastische Anstalt, H. Teith, and A. Floeck, Germany.*)
11,731. Separating the Husk of Locust Bean Kernels, P. C. D. Castle, Liverpool.
11,732. Plate for Storage Batteries, F. Grünwald, Liverpool.
11,733. Steam Generators, A. J. Boult.—(*J. B Loquet, and J. B. Ketelair, Belgium.*)
11,734. Steering of Horseless Vehicles, M. L. Blant, London.
11,735. Pigeon Traps, E. Harrison, London.
11,736. Otter Boards of Trawling Gear, J. Epton, London.
17,737. Storage of Acetylene Gas, E. Clausolles, London.
11,738. Plastic Substances, H. H. Lake.—(*M. Friedheim, Germany.*)
11,739. Softening and Purifying Water, O. Guttmann, London.
11,740. Pointing Wires, W. H. Spottiswoode and E. J. Passingham, London.
11,741. Tires for Wheels of Vehicles, D. Davy, London.
11,742. Gauge Glasses, J., E. T., T. W., and F. S. Tomey, London.
11,743. Closing Device, C. A. Floyd and A. E. Morrall London.
11,744. Elastic Tire for Cycles, R. McAllan and J. Henderson, London.
11,745. Elastic Tire for Cycles, R. McAllan and J. Henderson, London.
11,746. High Explosives, S. A. Rosenthal.—(*S. J. V. Romocki, Germany.*)
11,747. Cartridges, E. Rubin, London.
11,748. Tank Wagons, S. Fox and The Leeds Forge Co., Ld., London.
11,749. Air Guns, W. F. Markham, London.

30th May, 1896.

11,750. Side and End Tipping Wagons, C. W. Lyon, Dewsbury.
11,751. Spring Tube Scraper, C. Vincent, Belfast.
11,752. Fastener, &c., J. Pipan and L. Bangerter, London.
11,753. Pockets for Garments, R. Colegate and E. B. Woods, Folkestone.
11,754. Hoes, W. Savery, Bristol.
11,755. Cycle Chain Adjustments, J. Whitehead, Birmingham.
11,756. Ink-wells, S. Sauvage, London.
11,757. Utensil for Washing Dishes, &c., A. M. Unger, London.
11,758. Street-sweeping Machines, T. J. Robertson, London.
11,759. Rubbers for Carding Engine Condensers, A. Hardwick, Halifax.
11,760. Trusses, The Accrington Surgical Appliances Company, Ld., and W. J. Bell, Halifax.
11,761. Golf Balls, W. Park, jun., Glasgow.
11,762. Fastener for Window Sashes, T. White, J. Buchanan, and W. Wilson, Glasgow.
11,763. Cycle Gearing, W. Downie, Glasgow.
11,764. Tires for Vehicle Wheels, D. Halley, London.
11.765. Self-cleaning Sanitary Gulley, H. W. Swain, Bristol.
11,766. Roller Brake, W. Gardner, Harborne, near Birmingham.
11,767. Cranks for Bicycles, W. Hall, J. T. Blackett, and W. Hutton, Guisborough.
11,768. Doors for Gas Cooking Stoves, R. Clayton, Wolverhampton.
11,769. Spiral Roundabout, A. Marsden, Stockton-on-Tees.
11,770. Ladies' Tie-up for the Hair, E. A. Stamps, Birmingham.
11,771. Photographic Cameras, W. J. Lancaster, Birmingham.
11,772. Additions to Small-arms, A. Tunstall, Birmingham.
11,773. Fork-end Lugs for Cycle Frames, J. Johnson, Birmingham.
11,774. Looms, R. L. Hattersley and S. Jackson, Keighley.
11,775. Manufacture of Weldless Steel Tubes, J. Davies, Wednesbury.
11,776. Gas Engines, C. W. Siddle and R. Field, Huddersfield.
11,777. Velocipedes, F. J. P. Cheesbrough and E. R. Royston, Liverpool.
11,778. Lamps for Velocipedes, W. T. C. Gray, jun., and H. T. Livesley, Liverpool.
11,779. Electric Arc Lamps, J. G. Lorrain.—(*J. McLaughlin, United States.*)
11,780. Checking Delivery of Measured Quantities of Liquids, E. A. Pallister, Leeds.
11,781. Flat Stripping Motions for Carding Engines, J. Edge, Manchester.
11,782. Construction of Passenger Cars, T. W. Main, Dumbartonshire.
11,783. Electric Railways, H. H. Lake.—(*G. Ferraris and R. Arno, Italy.*)
11,784. Automatic Weighing Machines, T. S. Sheard, Liverpool.
11,785. Pump, C. Schey, Brussels.
11,786. Wool-beater, E. Beaumont, Brussels.
11,787. Automatic Flushing of Water-closets, C. Losange, Brussels.
11,788. Self-closing Tap, G. Laguens, Brussels.
11,789. Hygienic Feeding and Drinking Apparatus for Carrier Pigeons, E. Goemans, Brussels.
11,790. Refining Sugar, G. Ranson, Brussels.
11,791. Suet Cutter, W. Stabb and F. Little, London.
11,792. Bottle, W. Stabb and F. Little, London.
11,793. Cycle Mudguards, W. Stabb and F. Little, London.
11,794. Obtaining High Pressures, C. W. Siddle, R. Field, and W. G. Robinson, Huddersfield.
11,795. Vernier and Wind Gauge Combined, J. Wight, Ayr.
11,796. Cycle Lighting, G. R. Jaggs and A. Bodwell, London.
11,797. Abrading Machines, P. M. Justice.—(*A. R. Pritchard, United States.*)
11,798. Bicycle Driving Chains, S. Z. de Ferranti, London.
11,799. Tires for Bicycles, &c., S. Z. de Ferranti, London.
11,800. Electric Meters, J. Atherton, G. Knight, and G. Ellis, London.
11,801. Socket for Electric Lamps, J. Katzenstein, London.

11,802. Impregnating Wool with Oil, G. R. Smith, London.
11,803. Encaustic Tiles, J. E. Heath and J. Adams, London.
11,804. Child's Seats, W. F. Locke, J. H. Sargent, and P. Gallaher, London.
11,805. Tires, H. W. Tyler (Knight) and J. F. Dowding, London.
11,806. Pipe Couplings, M. F. Lancrenon and G. W. A. FitzGeorge, London.
11,807. Pneumatic Tires for Cycles, &c., R. Crittall, London.
11,808. Metallic Rims for Wheels, A. L. Kendrick, Birmingham.
11,809. Gas Mechanism, W. P. Thompson.—(*A. Dempster, Australia.*)
11,810. Bicycles, Tricycles, W. A. and A. A. Legg, Liverpool.
11,811. Retaining Aerated Liquids, S. Barnett, London.
11,812. Rings, H. H. Perkes, London.
11,813. Cables, W. A. Price, London.
11,814. Boats, F. W. Zimer, London.
11,815. Stoppers for Bottles, &c., R. D. Todd, London.
11,816. Lock, E. Draullette and A. E. Catois, London.
11,817. Regulating Warp Tension, G. W. Burrows, London.
11,818. Sieves, N. Greening and Sons and F. R. Crowder, London.
11,819. Battens for Weaving Looms, J. Poyser, London.
11,820. Manufacture of Tires, &c., T. Sloper, London.
11,821. Hand Tools for Miners, &c., E. Bingham, London.
11,822. Skirt or Garment, B. Polich and O. Beyer, London.
11,823. Cart, H. Scheller, London.
11,824. Carriage, C. Miethe, London.
11,825. Mail-carts, R. R. Thom, Kilmarnock.
11,826. Protective Covers, B. Lobee and M. Callahan, London.
11,827. Counter for Looms, A. J. B. E. Darras, London.
11,828. Apparatus for Drying Fabrics, T. Bradford, London.
11,829. Swansea Plate, W. T. Lougher, Swansea.
11,830. Door Knocker, A. King, London.
11,831. Motor Carriages for Roads, M. L. Blant, London.
11,832. Using Volatile Substances, J. Bengue, London.
11,833. Toughening Manganese Steel, R. A. Hadfield, London.
11,834. Wheels, E. Latham, London.
11,835. Tires for Cycles and Vehicles, S. H. Sharp, London.
11,836. Taking Photographs, J. Terme and A. de Maroussem, London.
11,837. Motor Carriages for Roads, M. L. Blant, London.
11,838. Railway Permanent Way, G. B. V. Scharberg, London.
11,839. Extracting Gold from Ore, A. S. F. Robinson, London.
11,840. Shafts for Carriages, &c., F. D. Bernier, London.
11,841. Velocipedes, D. Pascual-Hernandez, London.

1st June, 1896.

11,842. Explosives, G. G. André and C. H. Curtis, London.
11,843. Puncture-proof Pneumatic Tire, E. Oades, Wokingham.
11,844. Hat Retainer, C. H. Raddatz, Birmingham.
11,845. Castor, W. U. Coates, Fairfield.
11,846. Condensing Water from Steam, W. Weir, Glasgow.
11,847. Making Tiles and Quarries, J. E Brindley, Hanley.
11,848. Nickel Muffles, J. H. Gartrell, Penzance.
11,849. Steering Gear, T. H. Poole and T. W. Wright, Clonakilty.
11,850. Tire, J. Harding, Wolverhampton.
11,851. Paper Threader, L. Fletcher and A. H. Tuer, Wigan.
11,852. Rotary Hutch Tipplers, T. Thomson, Glasgow.
11,853. Envelope, J. B. Wilson, Glasgow.
11,854. Pole or Rod Holders, &c., G. Riley, Leicester.
11,855. Lighting and Heating Apparatus, P. Fraser, Glasgow.
11,856. Potters' Kilns, H. Cartlidge, Longport.
11,857. Fixing Screw Propellers, J. K. Oldfield, London.
11,858. Electrically-driven Pumps, J. C. Merryweather, London.
11,859. An Automatical Fruit Tree, G. Fritsche, London.

11,970. Frame for Miners' Lamps, M. B. Baird and T. Thomson, Glasgow.
11,971. Guard for Ships' Tables, R. C. McCunn, Glasgow.
11,972. Gas Engines, J. Wolstenholme and J. F. Bennett, Sheffield.
11,973. Movable Platform for Lamp-posts, A. Dalolry, Ealing.
11,974. Gas Burners, C. W. Davis and H. C. Turner, London.
11,975. Seats or Saddles for Velocipedes, J. Harris, London.
11,976. Machines for Mixing Syrup, J. Werner, London.
11,977. Machines for Cooling Syrups, J. Werner, London.
11,978. Tying Packages, C. A. Burr, H. Ewell, G. M. Flumerfelt, and A. G. Griggs, London.
11,979. Wood-working Machinery, H. McD. Jessop and L. Barnett, London.
11,980. Road Carriages, A. H. Adcock and W. Corteen, Birmingham.
11,981. Electrical Indicating Apparatus, J. G. Lorrain.—(*M. Pfatischer, E. S. Hosmer, and H. Binney, United States.*)
11,982. Speed Indicators, J. G. Lorrain. — (*M. Pfatischer, E. S. Hosmer, and H. Binney, United States.*)
11,983. Draught and Dust Excluder, R. de M. Lawson, London.
11,984. Chain Gear, G. G. Bauve, fils, and P. V. C. Hirschfeld, London.
11,985. Electric Arc Lamps, C. E. H. Edman, London.
11,986. Card Game, G. Tout, London.
11,987. Tubular Steam Generators, J. J. Cain, London.
11,988. Bicycles, H. Hardy, London.
11,989. Pipe Plug, F. Williams, London.
11,990. Frictional Gear, J. P. Maginnis and R. Harrison, London.
11,991. Pneumatic Cushion Tire for Cycles, T. J. Phipps, Watford.
11,992. Mechanical Movement, J. Polke, London.
11,993. Cycle Tires, W. J. T. Goatley and A. Hunter, London.
11,994. Motor Driven Cycles, E. J. Pennington, London.
11,995. Aerial Navigation, E. J. Pennington, London.
11,996. Boilers, C. D. Holmes, London.
11,997. Spring Latch Runner, F., W., E., and H. Claughton, London.
11,998. Mud Guard, C. G. Buik and G. S. Ullathorne, London.
11,999. Marine Telegraphy, R. J. Crowley, London.
12,000. Velocipedes, J. W. Cottee, London.
12,001. Support or Rest for Velocipedes, C. Lester, London.
12,002. Driving Gear, C. D. Abel.—(*The Gasmotoren Fabric Deutz, Germany.*)
12,003. Starting Gas Engines, C. D. Abel.—(*The Gas motoren Fabrik Deutz, Germany.*)
12,004. Flower Holder and Dress Fastener, R. C. M. Sterling, London.
12,005. Magic Lanterns, R. Ehrlich, London.
12,006. Brakes for Road Locomotives, F. J. Burrell, London.
12,007. Bottle Stoppers, H. H. Lake.—(*G. W. Steffens, United States.*)
12,008. Drying Granular Substances, T. T. Oliver, London.
12,009. Preventing Rattling in Couplings, J. W. Willard, London.
12,010. Scales, E. N. Gilfillan, London.
12,011. Brakes for Railway Trains, A. M. Willets, London.
12,012. Hat Ventilators, D. B. Metchim, London.
12,013. Wire Ropes, G. G. M. Hardingham.—(*Felten and Guilleaume, Germany.*)
12,014. Mud Guards, W. P. Thompson.—(*H. Engelbreit, Germany.*)
12,015. Saddle Support, W. P. Thompson.—(*Haag and Saalmüller, Germany.*)
12,016. Preventing Stoppage of Drains, J. Edmundson, Liverpool.
12,017. Tires, R. Buchanan, Liverpool.
12,018. Tires, A. M. Reveley and M. L. Barbeau, London.
12,019. Rotary Cutters, M. T. Denne, London.
12,020. Tins for Preserving Meat, W. E. Jope, London.
12,021. Hat Fastener, W. A. Collett, London.
12,022. Shoes, J. Wenzel, London.
12,023. Saddle Pins for Cycles, S. A. Parkes, London.
12,024. Buttonhooks, S. Wigglesworth, London.
12,025. Support for Sleeves of Garments, H. Loeb, London.
12,026. Bicycle Support, H. S. King, London.
12,027. Fibre Extracting Machine, V. B. F. Bayley. —(*F. J. Moden, India.*)
12,028. Caps for Electric Incandescent Lamps, R. J. Bott, London.
12,029. Clothes Drying Apparatus, L. H. Wood-Seys, London.
12,030. Tires for Bicycles, &c., H. H. Sturges, jun., London.
12,031. Ladies' Garment Hook, E. L. and A. Vaughan, London.
12,032. Axle Bearings for Cycles, &c., P. C. Lawless, London.
12,033. Cycle Pedals, P. C. Lawless, London.
12,034. Brake for Pneumatic Tires, W. Panter, Beckenham.
12,035. Cycle Stand, J. Henderson and R. McAllan, London.
12,036. Dies for Forming Nail Strips, S. M. Cutter, London.
12,037. Cheque Blanks, G. H. Rogers, London.
12,038. Railway-car Coupling, G. Schubert, London.
12,039. Transmitting Electric Signals, G. Marconi, London.
12,040. Caps for Air Valves, D. Doherty.—(*G. B. Doherty, India.*)
12,041. Machinery for Motor Cars, W. R. Smith, London.
12,042. Steam Generator, G. Viggars, Newcastle-under-Lyme.
12,043. Pencil Holders, J. Lee, London.
12,044. Meter for Reckoning Distance Traversed, P. Sylva, London.
12,045. Machines for Separating Light, H. Secks, London.
12,046. Generating Acetylene Gas, M. C. A. Fourchotte, London
12,047. Generating Gas, M. C. A. Fourchotte, London.
12,048. Photographic Shutters, G. J. F. M. Mattioli, London.
12,049. Boats, A. J. Hook, Surrey.
12,050. Removable Clips, E. Levison and C. I. Steiner, London.
12,051. Bells, E. Levison and C. I. Steiner.—(*H. Dissner, Germany.*)
12,052. Action of Bells, E. Levison and C. I. Steiner. —*H. Wissner, Germany.*)
12,053. Recovery of Zinc, &c., H. R. Angel, London.
12,054. Steam Turbines, A. J. Boult.—(*J. Comas, ——.*)
12,055. Apparatus for Producing Acetylene, G. Kern, London.
12,056. Metallic Threads, M. L. Ross.—(*E. Oberlé, France.*)
12,057. Watering Plants, A. J. Boult.—*G. B. Martinetti, Italy.*)
12,058. Looms, B. Hilbert, London.
12,059. Steam Generators, S. Lacavalerie, London.
12,060. Rotary Engines and Injectors, S. Lacavalerie, London.
12,061. Bottles, L. C. Werner, London.
12,062. Pipes, A. F. Volk, London.
12,063. Bottle Attachments, M. and L. W. Tebbetts, London.
12,064. Guards for Lamps, &c., S. N. Goodman, London.
12,065. Bottles, J. H. Green, London.
12,066. Rod Fastening, C. Schwinke, London.

3rd June, 1896.

12,067. Till, G. H. Himus, Cambridge.
12,068. Ventilation, W. Birch, Sheffield.
12,069. Machines for Cutting Wood, R. J. Lines, Northampton.
12,070. Transmission Dynamometers, W. E. Dalby, Cambridge University.
12,071. Billiard Cue Tip, J. R. Sutton, London.
12,072. Ladder Platform for Roofs, R. Beckett, Wilton.
12,073. Soaps, J. M. C. Grierson, London.
12,074. Rotary Motors, C. Burgess, King's Heath, Worcester.
12,075. Pneumatic Tires, J. Taylor, St. Helens.
12,076. Explosion Engines, W. Rowbotham, Birmingham.
12,077. Gearing for Vehicles, W. Rowbotham, Birmingham.
12,078. Horse Collars, D. Bowen and W. G. Cummings, Swansea.
12,079. Making Tubes for Cycle Frames, C. Binks, London.
12,080. Pattens, W. Brown, Swansea.
12,081. Invertible Label Damper, T. F. Lynch, London.
12,082. Fixing Handles to Cycles, J. B. Belcher, Birmingham.
12,083. Pneumatic Tires, B. Fox, Manchester.
12,084. Bicycles, W. Carson, Glasgow.
12,085. Brush and Broom Fastener, G. Shelvoke, Birmingham.
12,086. Combing Machine, J. Stake and A Stead, Halifax.
12,087. Brakes for Railway Wagons, L. W. Williams, Glasgow.
12,088. Cotton Spinning Machinery, J. Lord and T. Wilson, Tyldesley.
12,089. Fastenings for Broom Handles, J. H. Filbee, Birmingham.
12,090. Stoppers, A. J. Logan, London.
12,091. Walker's Mudguard Brake, J. Walker, Birmingham.
12,092. Cycle, &c., Hubs, H. Hiscott and J. Andrews, Birmingham.
12,093. Button Fasteners, &c., A. C. Twigg, Birmingham.
12,094. Substitute for Human Milk, T. Drewery.—(*M. V. Hagen, Holland.*)
12,095. Cog Wheels for Chain Driving, E. C. Bellamy, Birmingham
12,096. Bicycles, T. W. Sheffield, Liverpool.
12,097. Wheels of Cycles and Vehicles, W. Booth, London.
12,098 Cycle, &c., Tires, J. T. and S. E. E. Stephen, Leicester.
12,099. Water-closet Pans or Basins, J. C. Martin, London.
12,100. Gear Chains of Cycles, E. L. Tournet, Birmingham.
12,101. Reversing Valves of Engines, T. R. Robertson and W. E. Moss, Liverpool.
12,102. Hat Fastener, T. W. and M. Marsters, Nottingham.

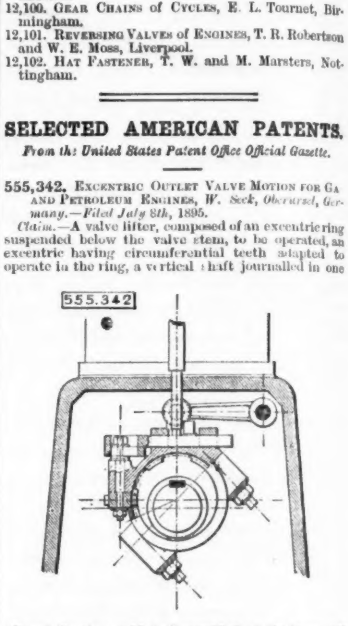
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

555,342. Excentric Outlet Valve Motion for Gas and Petroleum Engines, *W. Seck, Oberursel, Germany.—Filed July 8th*, 1895.

Claim.—A valve lifter, composed of an excentric ring suspended below the valve stem, to be operated, an excentric having circumferential teeth adapted to operate in the ring, a vertical shaft journalled in one edge of the ring, said shaft provided at its lower end with a worm wheel adapted to be operated by the excentric, and at its upper end with a cam and a slide, adapted to be operated by the cam, said slide provided with an upwardly projecting pin, whereby the valve stem is operated, substantially as set forth.

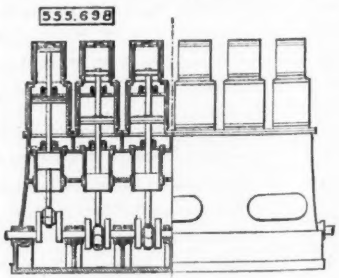
555.342



555,698. Balanced Steam Engine, *J. J. Heilmann, Paris, France.—Filed December 1st*, 1894.

Claim. (1) A balanced engine having a number of cylinders standing side by side with their axes in the plane of the shaft, said cylinders being a multiple of three or four or the equivalent thereof, and divided into two equal portions, the cranks in said two portions being symmetrical relatively to a vertical plane marking the line between the portions, and each symmetrical pair of cranks standing at the same angle and moving in the same direction, substantially as described. (2) An inverted vertical engine having six cylinders or series of six cylinders standing side by side of which the cranks are symmetrical relatively to a vertical plane cutting across the centre of the engine, the three cranks of each half of the engine being 120 deg. apart, and the pistons, piston-rods and other reciprocating parts having respectively exactly the same weight for each cylinder, substantially as and for the purpose hereinbefore described and illustrated by the accompanying drawings.

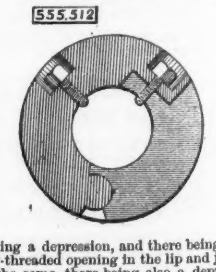
555.698



555,512. Split Slip Collar, *J. B. Johnson, Gouverneur, N.Y.—Filed October 12th*, 1893.

Claim.—A split slip collar comprising two parts secured together by a rocking groove and tenon joint, their opposite ends provided with a lip and jaw respectively, and shoulders against which the ends abut, the lip having a depression, and there being a coincident screw-threaded opening in the lip and jaw, a bolt engaging the same, there being also a depression in the collar and a screw-threaded opening, and a set-screw to pass through said opening and engage the shaft, as and for the purpose specified.

555.512



THE CRYSTAL PALACE EXHIBITION.

It is not too much to say that in the Crystal Palace is now to be seen the most remarkable and completely historical collection of carriages of all kinds for use on common roads that has ever been got together. It is true that the horseless carriage is more conspicuous by its absence than its presence, but that fact is in itself one fraught with instruction, and by no means devoid of importance. Of vehicles propelled by animal power, there are, however, enough to satisfy all but the most exacting. The exhibition of pictures and illustrations of locomotion is more than nearly complete, it is exhaustive; and we commend particularly to the attention of our readers the probably unique series of photographic reproductions of sculptures, paintings, tapestries, and old prints lent by M. Maurice Bixio, illustrating every conceivable form of vehicle from the days of Ancient Greece and Egypt to the nineteenth century. Many of the mediæval pictures are extremely quaint and curious. There are other collections got together by Sir David Salomons and Mr. Sennett, extending from the old French diligence to the modern French locomotive, in which will be found some historical engines, of which we fancy even Mr. Stretton has never heard. The entire display reflects infinite credit on Mr. Gillman and the Crystal Palace authorities.

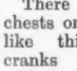
The principal interest, however, for engineers centres just now in the self-propelled carriages and vehicles of various kinds; and those who are now scheming and inventing, and devising and patenting, will miss an object lesson of maximum importance if they do not visit the Crystal Palace and see what is to be seen there. Of petroleum spirit motors there are seven or eight in or about the Palace; but, unfortunately, only two of these seem to be generally available for running in the grounds. These are two Arnold "Victorias," very similar in construction, and worked by Benz motors, driving at two speeds, with belts. There are two or three Delmar "Victorias," but these are run in a very erratic fashion by the representative of the firm, who sometimes takes them out and sometimes leaves them in the Palace for a week at a time. Sir David Salomons' carriage is also there, but Sir David allows no one to run it but himself, at which we are not surprised, because its works are a dreadful nightmare of parts. It would appear, however, that the display is at least as satisfactory as that at the Imperial Institute. There, there are a few more carriages, and no satisfactory place in which to show what they can do; whereas at the Palace there is ample room, and stiff hills and long ones to display all the characteristics, bad and good, of the horseless carriage. The display is small. The fact reminds us of well-known lines in the *Critic*, "The British fleet we cannot see because it is not yet in sight." The motor car we cannot have because it does not yet exist.

We think the time has come when we should speak out, and warn the public asked to take shares in companies being formed to supply horseless carriages of all kinds, that no vehicle is yet on the market which is free from radical faults of construction. That money should be subscribed to develope the horseless carriage, to try experiments, and work out something that will be satisfactory, is quite legitimate. But that is a very different thing from suggesting that it is possible at this moment to supply such demands as the British public will be likely to make now or in the immediate future. We can only speak of things as we find them. Leaving out for the moment the objections which may be urged, on the score of danger, to the use of petroleum spirit, let us consider what the carriages at the Crystal Palace demonstrate. In the first place, then, they are one and all unhandy. They have brakes, but these brakes will not hold them going down a steep hill; and in one case the attempt to stop resulted in tearing the india-rubber tire and smashing the brake gear. The vehicles cannot be stopped, started, run a few yards and stopped again in the way that would be necessary for street working. When running they have practically two speeds, say four miles an hour and ten miles, and they will not run with any certainty at any other speeds. They are in this respect subject to the well-known conditions of all explosive engines, the speed of which must be fairly constant. At times the engines cannot be induced to start, as much as twenty minutes being now and then expended in getting them to run, for no readily detectable cause. This is when they are in the hands of skilful men well accustomed to all their peculiarities. How the inexperienced man would get on with them we do not care to contemplate. The workmanship of the motors is about as good as that of a lawn mower. The coppersmiths' work, of which there is a good deal, is simply astoundingly bad. Soft solder seems to enjoy more favour than brazing. The one or two exceptions only make the defects of the other vehicles more prominent.

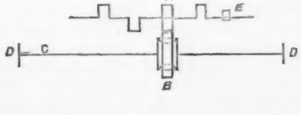
It may, and no doubt will be said that all these defects are remediable. This is true in part; it is true of workmanship and proportions, but it is not true of other things. Variable speeds can only be got by the aid of gearing more or less complex, because the motor must be run within very narrow limits at the same speed, whatever the exigencies of traffic may demand. All the carriages at the Crystal Palace are underpowered. They cannot start with the high speed gear on a level. How they will climb even moderate hills in bad weather, with muddy roads, we are not prepared to say; but already we hear that at the Imperial Institute the short ramp on the track has not been surmounted without the assistance of friendly hands to push. Given a nice level, or moderately level road, and plenty of room, they run with perfect ease, and give no trouble whatever. But none the less are they very unhandy, and unsuitable for working in crowded thoroughfares. Whether this unfortunate peculiarity can ever be overcome while an explosive engine is used, is more than we feel justified in saying. Reversing can be effected, but at a cost of complexity of gearing which few will care to encounter. All these facts should encourage English engineers to take the subject up. They have a clear course as far as competition is concerned; for we feel persuaded that no French or American machine yet produced and put in the market will either satisfy the British demand, or prove able to hold its own in competition with that which our own engineers can turn out. As we have said, we write of the horseless carriage as we find it; not as it may be; not as it appears on paper. We have not the least doubt but that all the Crystal Palace carriages, for example, could be remodelled with great advantage. Sir David Salomons has had his almost rebuilt. But this is not the point. That on which we insist is that the horseless carriages which have reached this country, or have been made here, up to the present, are little more than highly instructive toys, constituting an excellent groundwork for future operations, but a thousand miles from finality.

Nor is it to be supposed that the steam carriages shown at the Palace are much better. Our readers will find two of them not very far from the Galloway engine driving the electric lighting plant. These are very much alike, save in the form of the carriage body, with which we need not concern ourselves. We may confine our attention to one, the steam carriage built in 1892 to take part in the *Petit Journal* competition. A general description of this carriage appeared in our seventy-eighth volume. We may consider and criticise it in some detail with advantage; but we earnestly advise any of our readers interested in road locomotion to go and examine it for themselves. If they will apply at Mr. Sennett's office in the building they will be given every facility. Beginning with the carriage as a vehicle, it will be seen that the front wheels are much too small. The "fifth wheel," or fore carriage, and central pin are inadequate to prevent that "tucking in" of the fore carriage under the main body of the vehicle to which there is always a tendency. When a horse or horses *draw* a vehicle, the traces being attached to the fore carriage, the tendency is to pull the wheels out in front, and the "fifth wheel" may be a small affair having little to do. But in the self-propelled carriage, as in the traction engine, the leading wheels are *pushed* instead of being pulled; and it is easy to see that if they dropped into a small transverse rut in the road they might be doubled up under the carriage. We have seen this very doubling up occur to two ploughing engines in succession in trying to cross a stubble field. The evil is much aggravated by the small diameter of the wheels.

Turning now to the hind wheels, we find that strong and well designed as they are they have been shaken to pieces by the faulty method of driving adopted. On the hub of each wheel is fixed a pitch chain wheel. This wheel is not more than an inch or an inch and a-quarter thick; its boss constitutes a brake drum. The diameter of the whole is so small that a very heavy stress is brought on the spokes in the hub. The chain wheel ought to have been very much larger and secured to the spokes near the felloes. The chain pins are so small and short that they are much worn. The stress on the chain and the wheels is the greatest possible, instead of the least trouble. The brake consists of a strap of flat wire rope round each hub drum; it is, no doubt, very powerful, and so it must be, because the Serpollet engine and boiler are so worked that, as is well known, there is no throttle valve, and the engine is stopped by shutting off the feed, and will always make a few revolutions with the water remaining in the boiler. The brake will, however, bring the carriage up almost dead; but, as we have said, at the expense of greatly stressing and straining the wheels. The boiler is of the type with cross tubes set in a square casing, the tubes being in cross section like the annexed sketch. The fire-door is very inaccessible, and the grate is so high that it is a puzzle to us how a fire more than a couple of inches thick could be carried; but to burn coke to advantage a heavy fire is needed. The grate is very small, and we believe that, as a matter of fact, steam was kept up with much difficulty, especially going up hill.



There are three horizontal cylinders with the valve chests on top. The arrangement of the crank-shaft is like this. Two cranks close together, then an interval, in which is mounted a steel spur pinion A, which gears into a spur wheel B, about three times as large, on the second-motion shaft. This wheel contains the jack-in-the-box bevel wheels shown by dotted lines in the diagram. At E is an excentric, working the feed pump. Our sketch diagram is a plan. The whole is right under the foot-plate, just where it can best get dust from the road and coal and cinders from the foot-plate. The second-motion shaft is very light; the proportions, indeed, throughout will not commend themselves to English engineers, and it is evident that certain strengthening parts have had to be added. The workmanship is inferior throughout.



Here, again, it may be said that all this can be modified and improved. That is quite true. It is for this reason that we commend the Serpollet carriage to the attention of those designing steam carriages. Compared with the Randolph carriage close by, the French coach seems very feeble; yet, it must be remembered, that it has been run quite successfully for a time in France, and we hope to see it running again in the grounds of the Palace. The owners, indeed, have stipulated that it is only to run during the last fortnight of the Exhibition. Why, we are unable to say.

We wish we could say something about the Ward electrical omnibus; but it is only the carriage part that is to be seen, and as the underframe and driving gear has not yet arrived we are compelled to silence. The old Ward omnibus stands close by; a glance is almost enough to show that however excellent as an experiment it could never attain complete success. Indeed, Mr. Ward admits as much by providing what is claimed to be very much better, one of the special advantages being that in some way not yet explained the batteries are prevented from being run down too fast. It is a very tempting thing to turn on a tremendous current to get out of a hole or ascend a short steep incline like a high pitched bridge. But there is always the imminent risk of dissipating the insulation of the armature in a flame, or of irreparably injuring the accumulators. We believe that the underframe carrying the motors is being made in Leeds, and is daily expected at the Palace.

THE INSTITUTION OF NAVAL ARCHITECTS IN GERMANY.

The Earl of Hopetoun, in returning thanks to Bürgermeister Doctor Mönckeberg for his courteous address, gracefully acknowledged in a bright little speech the exceeding cordiality of the welcome which we had received. He was charmed to observe that his advice to the members—to accept the invitation generally—had been acted on so implicitly. He only hoped it was not too implicitly for their hosts. But he wished to explain that the Institution of Naval Architects was a cosmopolitan society. It was certainly not British in an exclusive sense. It represented the naval architectural skill of all great naval powers, for members from all these countries were included in its ranks. Hence there was all the more cogent reason for the warmest sense of international brotherhood when its members met together. It was the scribblers to papers who did all the mischief, and stirred up disturbances amongst nations between whom the strongest natural ties existed. He remarked that two important papers were being read that day, which reminded him in the most distinct manner that German enterprise has gone ahead. Of that they had a remarkable, and at the same time agreeable object lesson, in the splendid ship which brought them over. They had seen, too, on Monday, the immeasurably valuable improvements in the Port of Hamburg. Perhaps the contemplation of their importance might occasion anxiety as well as admiration. But rivalry and competition are the true elements of success. He meant peaceful rivalry. It must never be forgotten, moreover, that Germans and Britons came from the same old stock. The world was large enough for both, and there was no need for them to tread upon one another's toes.

In the discussion which followed the paper by Mr. F. A. Meyer, upon the "Maritime Position, &c., of the Port of Hamburg," published in our last impression, Mr. Brown said a few words in regard to the question of the portable steam cranes, the introduction of which, by his firm, into the wharfage appliances of the port, had been so appropriately noticed by Mr. Meyer in his paper. We should have mentioned that the lecturer had prepared a most elaborate and valuable series of plans, of large size, which were on view at the Concert Haus, and which we regret not to be able to reproduce.

Sir E. J. Reed expressed his sense of pleasure and admiration at the paper which had been read. It was an important and concise contribution to the history of that great port, the increase of whose resources had hardly been understood. He thought that if any place of similar character in our country had an analogous history—though not in so considerable a sense—it was Cardiff! He was particularly struck by the energy and enterprise observable everywhere whilst running through the harbour basins on Monday afternoon. The majestic Elbe, with its great arms stretching out in all directions, embraced the commercial enterprise of the world. Cardiff was, of course, only a centre for coal exportation. Hamburg supplied the wants of the Continent of Europe in the widest sense. The reception of the Society of Naval Architects in Hamburg had been a panorama of magnificence.

Lord Hopetoun remarked, in regard to this capital and instructive paper, that, as a direct descendant of the Picts and Scots, he was exceedingly glad that Hengist and Horsa came over from Germany. Perhaps one reason for their remaining in England and not returning to their own country, was that they had uncomfortable ships. They had not a Fürst Bismarck to return in.

Mr. Meyer replied that he only hoped, as the members of the Institution were so pleased with their reception, that they would imitate Hengist and Horsa by remaining in the country to which they had come.

A paper was then read by Mr. C. Ferd. Laeisz, Chairman of the Hamburg Chamber of Commerce, upon "Shipbuilding in Germany." He pointed out that when wooden sailing vessels were superseded by steamers of iron, the vast natural resources of Great Britain, allied to her immense capital and wonderful enterprise, prevented other states from keeping pace with her. Germany still laboured under considerable difficulties. The great cost of materials, and the restrictions imposed by the law in the employment of juvenile labour stood in the way of employers. Hence the quantity of tonnage turned out was small compared with England. Some of the craft, however, "made in Germany" might be worthy of the Society's notice. Two boats were building now for the North German Lloyds, one at the Vulcan Yard, Stettin, the other by Mr. Schichau, at Dantzic. Their dimensions were 625ft. between perpendiculars, 66ft. beam, 43ft. moulded depth, displacement, 20,000 tons, indicated horse-power, 28,000. Mr. Laeisz noticed that the new German steamers showed a coefficient of fineness seldom over 0·76, whilst many under the British flag approached, or even exceeded 0·8. Forced draught was not extensively believed in in Germany. It had been found necessary to strengthen some of the large new sailing ships beyond the requirements of Lloyd's rules. Germany had not seen the wisdom of imitating the English Load Line Act, but her Bulkhead Committee was "pondering over the solution of the problem of rendering her ships unsinkable."

In the discussion which ensued, we cannot but think that an undue spirit of self-depreciation was observable amongst some of the speakers on the British side. Perhaps it was out of a sincere desire to render a tribute of homage and admiration to the remarkable energy and ability of their hosts, as exhibited in the perfecting of the city of Hamburg as a great commercial port. Nevertheless, we are of opinion that the respect of others is not likely to be gained by running ourselves down wholesale.

Mr. Martell noticed that much of the machinery which we employ is of an ancient character, whilst Hamburg shipbuilders appeared to have everything brand new. His position as a guest in that hospitable country, and after so splendid a reception had been accorded to him and to his colleagues, forbade criticism, even if there was any to offer. He had seen the day before, upon the wharves, and in the shipyard workshops, magnificent appliances, and was tempted to wonder where they could have come from, until he was reminded of the works of Messrs. Krupp and Co., at Essen, and their unrivalled workmanship. In regard to what was said in the paper upon the accidents which had occurred to oil tank steamers, it must be remembered that, at first, shipbuilders did not realise fully the conditions under which oil was carried in bulk, nor the strains which were brought to bear upon the bulkheads. He observed that although Germany built her ships under trying restrictions as regarded material and labour, they could be run more economically, because there was better discipline amongst the crews and other employés. The fact of there being no Load Line Act rendered Germany independent, but she was following a bold course in this as in other respects, an illustration of this being found in the circumstance that she was just turning out a great cargo vessel to carry 14,000 tons of dead weight. He must, however, find one fault with the paper, and protest against the modification of Lloyd's rules, and the strengthening of its formulæ as to scantlings, &c. He would say, in conclusion, that Germany had begun her enterprise in shipbuilding where we left off.

Sir W. H. White did not acquiesce in the view of the Load Line Act which was taken by the writer of the paper, and gave unqualified testimony to the efficiency and importance of Lloyd's rules. Mr. Martell was quite right in indicating the position which Germany now occupied, as beginning where we left off. It was, indeed, better to come after and improve upon the work of other nations, in shipbuilding or anything else. Messrs. Blohm and Voss had been born at the right time, and they had opportunely taken advantage of what they had learned in England. It is a proud position to occupy, that of an instructor, and to have pupils growing up around one; yet sometimes one almost feels inclined to wish that he had been born later. As regards the restrictions and difficulties of manufacture in Germany, he could not help thinking that Germans bought their material most economically, whilst they employed the cheapest labour. They had a great advantage in this last respect, which was a most important consideration when we illustrate it by saying that 70 per cent. of the cost of work in a torpedo gunboat is labour. He would not himself personally invest money in a shipbuilding yard which did not employ the cheapest labour and materials. He considered that we had a vast deal to learn from Germany in everything.

Mr. Archibald Denny paid a graceful little compliment to the value of the work of instruction which he had received under the teaching of Sir W. H. White, whilst he remarked that Hamburg had gone ahead of Great Britain as her pupil. He would never advise Germany to introduce the load-line law. As regards the question of bluff coefficients, it was imperative to build mercantile vessels of this character, as shipowners demanded them. They were under the impression that they had already gone too far in reducing the solid rectangle.

The Earl of Hopetoun, in proposing a vote of thanks to Mr. C. Ferd. Laeisz for his excellent paper, said that he had by it added one more item to the load of gratitude which we owed to our kind and hospitable hosts.

A paper upon the subject of "Recent Improvements in Docks and Docking Appliances," which we publish elsewhere, was then partly read by Mr. Lynel Clark, but, owing to the pressure of time engagements for the day, it had to be considerably curtailed. This, though necessary, was a pity, as the paper was of considerable value and importance, and it is to be regretted that it could not have been introduced during the second day's readings, in the presence of the Emperor, in lieu of the somewhat uninteresting dissertation by Professor Elgar upon the "Classification and Relative Power of Warships"—a question which is purely academic. The paper had, too, a peculiar application and interest attaching to the visit of the Institution of Naval Architects to Hamburg, as the docks and dock appliances to which it alludes could be seen in full swing at the shipbuilding yards of Messrs. Blohm and Voss, and the Reiherstieg Schiffswerfte. The initial cost of graving docks for the repair of vessels, and the immense labour and expense of pumping them out for use, which is, as Mr. L. Clark points out, in inverse ratio to the sizes of the vessels to be docked, should prohibit their employment for this service. Yet, as we know, this system is commonly employed in our country, more especially in Government dockyards. The rapidity with which the floating docks, whose use is advocated in this paper, can lift a vessel and place it in readiness for examination, is very remarkable. It is said that the present Hamburg large dock lifts a vessel of a dead weight of 5000 tons clean out of the water in a space of thirty-two minutes, and that, with the new North Shields dock, this rapidity has been still further increased, as it will lift a vessel of a displacement of 6000 tons, and a draught of some 20ft., in a space of thirty minutes.

The proceedings at Ludwig's Concert House were terminated with the proposal, by Sir W. H. White, of a cordial vote of thanks to the Bürgermeister, Senate, and people of the port of Hamburg, and to the Reception Committee who represented them. He remarked that this Committee represented all who were great and influential in Hamburg, whether socially or officially. When he had stepped upon the Fürst Bismarck he was welcomed by Herr C. Ferd. Laeisz, as upon German soil. This welcome had been emphasised more and more warmly as events wore on. We had felt the cordiality of our welcome most sincerely. In the harbour, as he landed, as he moved along the streets, he realised that it was a royal one in every sense.

Herr Laeisz replied that Hamburg was delighted to see the Institution of Naval Architects. The meeting was one which would tend to cement most closely the ties and intimacies between us, both nationally and socially.

The carriages, which had been so kindly provided by the city of Hamburg, then rapidly swept the visitors along the fine wide streets and boulevards of the town to an elevated spot near the new bridge, which spans the site of the old fortifications. Here at the Fährhaus, looking out upon the broad and glittering bosom of the Elbe, amidst shady trees and terraces, luncheon was served to the entire body of members and their lady *compagnons-de-voyage*. After the discussion of this—which we are bound to confess was a far more animated one than that of the papers—the whole party was driven out of the town around the beautiful waters of the Alster Lakes, across which they had steamed the night before. A countless variety of fine villas and mansions dotted the green slopes which led down to the water's edge, and these were embowered in trees and their lawns bright with flowers.

After an hour and a-half's breathing space, devoted by the ladies of the party to the unpacking of their pretty frocks, they were carried off in the same carriages to the St. Pauli landing stage and embarked on board the Prinzessin Heinrich, newly built by Messrs. Blohm and Voss for the Heligoland service, for conveyance down the Elbe to Blankenese, a picturesque village upon the hilly right bank of the river, where they were entertained at dinner by the citizens of Hamburg and their wives. After a most excellent repast, a few hearty speeches of welcome and reply were made, during which Sir E. J. Reed pointed out how the superior education of Germany had contributed to her success in shipbuilding, the party descended the hill side to their steamer and started for the town. It was now dark, and as the paddles began to revolve slowly, the party gradually found themselves at the head of a large procession of small steamers and launches lighted up most gaily. It was 12 p.m. before the procession ended, and the visitors had been driven back, delighted with the reception accorded to them, to their several hotels. Thus ended the visit of the naval architects to Hamburg.

On Wednesday morning early the visitors gathered at the railway station, where the thoughful kindness of the reception committee had arranged that they should have a special train in readiness for their conveyance to Berlin, only one halt to be made on the journey at Wittenberge for lunch. Capital arrangements were made by the committee, aided by the indefatigable secretary of the society, Mr. George Holmes, for the transport of the baggage, which by this time, swollen by the addition of that belonging to the passengers who had arrived independently at Hamburg, had assumed most formidable dimensions.

At a little after 2 p.m. the train steamed into the Lehrter Station in the last-mentioned town, after crossing the fertile plains of North Germany for some 140 miles, during which not a single cutting or embankment had been negotiated, so flat is the surface—a sandy expanse, but green and excellently cultivated, with pasture or grain fields peeping out between small fir woods and groups of silver birches. The villages and farms were few and far between. It is clear that the crowding of the inhabitants into the town of Berlin, whose population has enormously increased since the war of 1870-71, has thinned the country districts. This Germany will live to repent, as has been the experience of our own country.

It was very hot in Berlin, and the sun-glare very powerful in the streets, but the watering arrangements are so good that, although the city is built upon a sandy plain, there is very little dust being blown about. The banks of the Spree are a model of neatness. In the commercial quarters of the town every available square inch of the water's edge is taken up by goods. Barges are seen loading and unloading sand, not by clumsy baskets, but by rows of neat revolving bands, with buckets upon them. Bricks are piled neatly in stacks, so that the contents of these latter could be ascertained in a moment. There are advertisements on the wharfs, but they are clear, and do not obstruct one another. The street advertisements are all on tall columns, specially constructed.

In the evening the members of the Institution and ladies were entertained at the New Royal Opera House, Berlin, by the Imperial German Government. Supper was served in the saloons adjoining the theatre, and was a very substantial affair altogether.

On Thursday, June 11th, the members of the Institution, as well as the ladies, were all in attendance in the Great Hall of the Technical High School. The Emperor had notified his intention of being present at the reading of the papers. At a little after ten o'clock the large proportion of the party, who had remained outside waiting for the coming of the Kaiser, filed into the room, amidst lines of smart-looking students in handsome uniforms, with swords and small scarlet caps. Then a side door was opened and the Emperor entered, and was received with hearty cheers.

The following inaugural speech was then delivered by his Excellency, Admiral Hollmann, after the Emperor had taken his seat, and his presence had been duly acknowledged by the speaker:—"My lord, ladies, and gentlemen, on behalf of my Imperial German colleagues I bid you heartily welcome to the German Empire. Our thanks are ever due to the Institution of Naval Architects for the improvements in shipbuilding which they have inaugurated. The admiration of the world has always been called forth by shipbuilding perfection. Architecture in building may call for admiration, but a building is inert. 'A ship, however, is a thing of life!' By the art of shipbuilding, great battleships, great Atlantic liners, great cruisers, beautiful yachts are evolved. Who has created all these? The Institution of Naval Architects. The interest taken in your visit to this country is evidenced by the presence in our midst of our beloved gracious sovereign. (Loud and prolonged cheers.) May your pleasure here be great, and may all your efforts be crowned with success."

The Earl of Hopetoun briefly responded, assuring his Majesty the Emperor—himself a member of the Institution—of the deep sense of gratitude which the Institution experienced at the honour which he had conferred upon it by his presence in their midst. He, the Emperor, had himself a practical knowledge of the ships of all nations. In regard to the paper which was about to be read, it would be well in the discussion to avoid comparisons between Imperial German and British navies. Each nation had definite requirements as to conditions of service of the vessels employed, and must have its own peculiar models to meet those requirements. But whichever navy was under consideration, whether that of Germany or that of England, it must, if efficient, be of world-wide usefulness. A powerful navy is a sure factor of peace.

Herr A. Dietrich, constructor-in-chief of the Imperial German Navy, then read a paper upon "Development in Design and Construction of German Men-of-war." This paper we published in our last issue. Herr Dietrich particularly noted the assistance he had received from The Engineer in respect to matters touching upon warship construction.

Sir William White remarked that this was a most valuable paper, and an important contribution to the history of the development of the German Navy. As Lord Hopetoun had said, the several requirements of each individual navy must be considered in the designs of men-of-war. Germany and England present different features in their requirements. There are also so many divergent views of naval officers to be consulted, even before those of the naval architect. There is the question of the weight of heavy guns forward and aft. Then the matter of boilers, whether they shall be cylindrical or water-tube, must be a point to be settled by the requirements of local circumstances. He had seen the greater part of the German warships afloat, and fully recognised their admirable points. We were certainly not too proud to come to Germany to learn, and the presence of the beloved sovereign of Germany showed the keenness of his interest in the matter.

Mr. Thornycroft thought that the two great points of interest in the paper were the application of electrical appliances to the German ships and the matter of boilers. He thought that electrical apparatus was especially valuable, as it was so simple and easy to repair. He did not, however, agree with the paper as to the use of tubulous boilers for short and broken periods of use. He preferred to keep his boilers going.

Lord Hopetoun seemed to think that the only material which should be inflammable on board ship should be the men.

A vote of thanks was given to Herr Dietrich for the paper, and Professor F. Elgar was called upon to read that upon "The Classification and Relative Power of Warships." It was a difficult subject to treat, and, although dealt with in a satisfactory manner by Mr. Elgar, interest in it fell rather flat. One or two interesting points in it may be noticed. Dr. Elgar states that "the cost of a ship increased at a rapid rate with growth in size—roughly, in proportion to the displacement in different types." Also that "as ships go on growing in size the weight of hull will absorb an ever-increasing proportion of the displacement, and that the remainder that is left available for the different elements of fighting power will become relatively less." He also said that "it certainly should be required of a warship that she would be reasonably safe after a single blow from the ram or torpedo." These three points are deserving of the utmost attention, and redeemed the otherwise dull nature of the paper in question.

The discussion of this paper was of little importance, with the exception of some remarks by Sir E. J. Reed and Sir W. H. White. The former said that the warship which is able to speak first, loudest, and most truly in the time of battle will be the most effective. The latter observed that the protective-decked ships of the Japanese at Yalu did not appear to suffer much during the action.

The Thursday meeting then terminated. We shall give in our next the result of a visit to the works of Messrs. Siemens and Halske, which took place in the afternoon of the same day.

HORSELESS CARRIAGE NOTES.

The Locomotive on Highways Bill was read a third time in the House of Lords on Tuesday, June 16th, and passed. Assuming that the House of Commons exhibit the same knowledge of the spirit of the times and the recognition of the requirements of the various industries and trades, we shall not long rest under the stigma of being the only nation that allows itself to be taxed by heavy penalties and restrictions on road transport.

The opinions of M. François Deloncle, député of the Lower Alps, concerning horseless carriages and their uses, are published by the *Petit Journal* of the 6th inst., at considerable length. He is of opinion that already sufficient has been achieved to show the possibility in the near future of the establishment of regular lines of vehicles connecting places not already connected by rail, and he is confident that the automobile will render unnecessary any extension of the light railway system.

With a view to the establishment all over France of the modern equivalent of the stage coaches of former days, but with the advantage of everywhere better roads, a great Société Nationale des Express Automobiles is proposed, and strongly supported.

"THE ENGINEER"

ENGINE POWER AND SELF-PROPELLED TRAFFIC.

By Sir DAVID SALOMONS.

THE technical and general Press have published a great deal of information concerning self-propelled vehicles. A large number of carriages have been described in detail, and the merits of such vehicles have been trumpeted, right and left, in advertisements duly paid for.

So far as I have been able to gather, nothing has been published in regard to the question which I may term the "kernel within the nut." By this I mean, what is really the horse-power required to do a given work on a high road? This matter has been solved long ago in respect to railways—for all inclines, and for all weights of trains; and there is no doubt that the problem has been solved many a time for the high road, but I do not believe that anything definite has so far been published on the subject.

It will naturally be imagined that to mount an incline on the highway would require more power than to mount a similar incline on the railway. This is not the case, although the power required to travel on a level road when compared with a given incline—the surface of such roads being equal—would be practically equivalent to the increased power necessary had it been a tramway, but the initial force required on the level in the case of a tram or railway would be very different to that of propulsion on a high road.

It is not my intention to compare the railway with the road, but to confine myself to the latter. Many years ago I made a number of experiments in regard to traction on good high roads. When the modern horseless carriage appeared I at once pointed out to the makers that the power placed within them was far too small, with one or two exceptions, for practical work in a hilly country. The main advantage of self-propelled traffic over horse traffic lies in the fact of greater speed, which within reasonable bounds is certain and regular, and consequently in being able to run hour after hour at a constant speed without fatiguing the animal drawing the vehicle, with the further advantage of easing the mind of the driver of any feeling of perpetrating a cruelty.

A vehicle which will travel at a given speed, say of twelve to fourteen miles per hour, no matter whether the country be flat or hilly, is a great factor in annihilating space.

Before my steam carriage with the Serpollet boiler was constructed, I was anxious that a series of calculations and experiments should be made in order to be fairly sure, in advance, that the result I sought was likely to be realised. The results are closely in accord with the experiments I made at an earlier date, and it may be of interest to those engaged in the manufacture of these carriages to have some information on the subject. In giving the figures, I take round numbers, which are quite close enough for all practical requirements.

I assume the carriage to weigh 2½ tons when laden, then on a good level road a speed of 7½ miles per hour can be obtained for 2⅓-horse power, and on a bad level road for 4⅓-horse power. To travel up an incline of 1 in 20 on a good road at the same speed would require 10-horse power, and on an incline of 1 in 10 on a similar road about 19-horse power would be necessary. It will be noticed from these figures that each succeeding horse-power necessary is practically double the preceding one. It will also be observed that the increased power required between a level rough road and an incline of 10 per cent., which is not uncommon in many districts, is practically as 1 to 5.

From these figures it is obvious that in order to travel at so slow a speed as 7½ miles per hour, whether on the level or a hill of 10 per cent. rise, in the case of a carriage weighing 2½ tons, when provisioned and laden, the vehicle must carry an engine capable of giving up to, say, 20-horse power. If a speed of 12½ miles per hour on a good road is sought, nearly 4-horse power is necessary; on a bad road, 7⅓-horse power; on a 1 in 20 incline, 16¾-horse power; on a 10 per cent. incline, roughly, 80-horse power. For a speed throughout at the rate of 15½ miles per hour on a good level road about 5-horse power is necessary; on a bad road, 9-horse power; on an incline of 1 in 20, 20-horse power; and for an incline of 10 per cent. rise, nearly 40-horse power.

If the weight of the vehicle when laden was, say, one ton, the horse-power necessary for similar speeds would be two-fifths of the figures given above. This I mention, because one ton is approximately the weight of most petroleum motor-driven carriages when laden.

If it now be desired to travel on the level and up hill at an unvarying speed of, say, twelve miles per hour, which speed would hold good for downhill also, since a greater speed would probably not be tolerated, it would appear, when it is taken into consideration that except in a few districts the roads are rarely what may be termed good in the strict sense of the word, such a carriage should carry an engine capable of giving from 2-horse power up to 12-horse power. Since the majority of the carriages in question are fitted with engines incapable of giving more than 4-horse power, the desired uniform speed of twelve miles per hour will, therefore, be reduced to one-third, viz., four miles per hour where a 10 per cent. incline is reached. This is what they realise in practice, and may be taken as a very good proof that the figures I quote are very approximately correct.

The general analysis given above is instructive, for the reason that it teaches two important facts which are essential when a given average speed is required: (1) That no vehicle is of much service for heavy work unless an engine capable of giving out not less than 30-horse power is fitted; (2) that for light traffic the engine should give not less than 12-horse power for the maximum.

That both these conditions can be fulfilled with steam has been proved, but in the case of petroleum-driven motors I do not think that the result has yet been satisfactorily obtained. To increase the power of the latter form of engine threefold, means in practice that its weight would be at least twice as great, and that more water would have to be carried for cooling the cylinder or cylinders, water in all probability being lighter than any form of cooling apparatus to do the equivalent duty. It is, therefore, clear that if the petroleum motor is to be heavier, the first conditions stand altered, and in consequence of the carriage being heavier, the speed will be reduced, or a still larger engine must be carried.

I therefore conclude, in the present state of our knowledge, that if the light petroleum-driven carriage is required to run at an average speed of twelve miles per hour on good and bad roads, where inclines exist up to a 10 per cent. rise, the carriage laden will probably weigh not less than 1½ tons and require a maximum of not less than 18 to 20-horse power.

So many statements have been made as to the capabilities of special types of carriages, that I consider this a proper time for the public to have every means of gauging how far such assertions are true, and the above information, although it does not pretend to be mathematically accurate, is true to within a very small percentage, and sufficient for all practical purposes.

In conclusion, it is only fair to say that by comparing the statements of the many makers of these vehicles, that although it frequently occurs that their statements are misleading, yet in a great number of instances they are approximately correct, but it will always be observed how slow petroleum-driven carriages are stated to be for the hills.

THE INCORPORATED GAS INSTITUTE.

ON the resumption of proceedings on Thursday, the 12th inst., Mr. W. J. Dibdin read a paper on "A Standard Photometer," and this was immediately followed by a paper by Mr. W. Sugg on "Photometers and Standards of Light." The object of Mr. Dibdin's paper was to suggest a form of photometer suitable for general adoption as a standard instrument for testing the illuminative value of coal gas. Mr. Dibdin's views are well known to gas engineers, and the present paper did not contain any fresh development, nor the record of any new work undertaken in their support. Briefly, he advocated the general adoption of a simple open-bar photometer, as first suggested by King, with the addition of a reversible holder for the Bunsen disc and mirrors, mounted in an easily movable box, and with velvet screens 12in. from each light to prevent reflection from other surfaces, and a screen to cut off direct rays from the observer. The photometer should stand near the middle of a well-ventilated but not draughty room, kept at a temperature of about 65 deg. Fah., and with walls coated with a dead wash. Mr. Sugg's paper was replete with historical matter very interesting to those anxious to learn how the modern forms of photometer and methods of gas testing have been evolved. He is of opinion that both the modified Evan's photometer as used in London, and the Letheby, which is also sanctioned by the Metropolitan Gas Referees, give equally trustworthy results, and he considers that if the pentane Argand standard were adopted in place of candles, the testing of the illuminating power of coal gas would be satisfactorily settled.

These two papers provoked much discussion, but, unfortunately, little criticism. Mr. Dibdin had asserted that Mr. Lewis T. Wright had misused the 10-candle pentane standard in some experiments, the results of which were unfavourable to it. In response to this challenge Mr. Wright explained his use of the standard, and amplified the account of his experiments. The confidence of the meeting in it was much shaken when Mr. Dibdin, in his reply, refused to remain its sponsor, and retreated from the discussion, on the plea that the recommendation of the standard by the last Board of Trade Committee placed it beyond the pale of common criticism. Mr. Dibdin should have refrained from remarks adverse to Mr. Wright's published work if he was not prepared to meet that gentleman's reply, and we hope to see him take an early opportunity to reassure engineers who are using his 10-candle standard that their confidence has not been misplaced.

A suggestion, said to be due to one of the London gas examiners, that the position of the disc at each observation on the photometer should be recorded by the impress of a spring-pointer on a paper scale placed on the photometer bar, instead of being read by the observer, met with general approval, and as it was proposed to have the record of the whole series of ten observations on one paper-scale invisible to the observer, the method seems calculated to remove any suspicion of his later readings being biassed by the knowledge of his earlier ones. But if the necessity for such a method of recording observations is admitted, it becomes a question whether the movements of the disc throughout the period of observation should not be traced by a pencil on a roll of paper. Such a record would be invaluable to counsel in arguing disputed cases of deficient illuminating power, and would afford the chief gas examiner a ready means of checking the work of his assistants. The question of errors introduced through defective vision of an observer appeared to be a momentous one to many speakers. There seemed to be some little doubt in the minds of many as to the issues here involved, and we therefore make no apology for a few words of explanation. There is the question of the purely personal equation, *i.e.*, as to whether two observers of tolerably normal eyesight, *cæteris paribus*, make similar readings. It has been pretty generally conceded that they do. There is, however, the further question as to whether the receptivity of the eyes of any one observer is the same. It is known that very many people credited with good sight can see better with one eye than with the other. The result of this unequal power of vision would be a tendency to make readings always to one side of the correct position of the disc. To obviate such a tendency, Mr. F. Beale and other speakers suggested that only one eye should be used in making observations, but there are obvious objections to the general adoption of such a plan. We were much surprised that those present at the meeting seemed unaware of the simple means of compensating for unequal receptivity of the eyes which the method of taking readings alternately from different sides of the photometer bar affords. As it is now conceded that it is desirable on other grounds that a photometer should be placed in the middle of a room, the necessary structural alterations of the instrument to permit readings to be made from either side of it would be but small.

The proceedings on Thursday afternoon opened with a paper by Mr. Frederick G. Dexter, of Winchester, on "A Season's Experience with Incandescent Public Lighting." He recommended the use of the bulb pattern light, with metal reflector, in place of the ordinary burners with glass or mica chimneys; in other respects he found the common bye-pass burner the best. The anti-vibration spring burners had proved no more satisfactory than the ordinary ones. At Winchester vibration had been deadened as much as possible by packing the lamp column with sawdust.

The author gave some interesting results of the effect on the illuminating power of incandescent lamps, of variations in draught, and air supply. To obtain the maximum efficiency the flame should fill, but no more than fill, the space enclosed by the mantle. The author's experience with 500 street lamps at Winchester showed an average consumption, inclusive of the bye-pass jet, of 3⅞ cubic feet of gas per light per hour, and an average of three mantles per light per annum for renewals. The glass bulbs were broken on half the number of lamps in use in the course of the year. In the course of the discussion on Mr. Dexter's paper, an invention by Mr. W. R. Clay, of Bolton, for minimising the effects of vibration on incandescent mantles was described. From the top of the pillar, ⅛in. brass pipe is carried out horizontally to a distance of about 1¼in., then bent at right angles, and carried upwards to the height of the chimney top. It is there bent into a coil of three turns, and carried down again alongside the chimney to the base of the burner, of which it forms the supply pipe and sole support. In effect the small diameter brass supply pipe thus forms a coil spring, from which the burner is suspended. This device, which is provisionally protected in all countries, was said to entirely overcome the disastrous effects of vibration from traffic on the mantles of street lamps.

At the close of the discussion on Mr. Dexter's paper, the President announced the election of the following gentlemen as officers for the ensuing year:—As President, Mr. C. S. Ellery, of Bath; as Vice-presidents, Messrs. J. Stelfox and S. Stewart; as Members of Council, Messrs. G. Winstanley, Isaac Carr, S. S. Mellor, and W. Cotton; and as Honorary Secretary, Mr. Andrew Dougall, of Tunbridge Wells. The President then presented, on behalf of the members of the Institute, a choice silver bowl to Mr. J. Hepworth, M. Inst. C.E., in appreciation of his several years' services as Honorary Secretary of the Institute. An illuminated address was presented to Mr. F. G. Burfield, the late Secretary of the Institute, and after the transaction of some formal business the meeting closed with a hearty vote of thanks to Mr. W. R. Chester for his services as President and Chairman. In 1897 the annual general meeting will be held at Bath.

THE NEW "DESTROYERS" NOW BUILDING.

THE following list comprises the whole of the new type of "fast destroyers"—forty-eight in number—now building to the order of the British Government by the different firms mentioned. Messrs. Yarrow and Company will be fully engaged for months to come on foreign orders.

Messrs. Laird Brothers, Birkenhead.

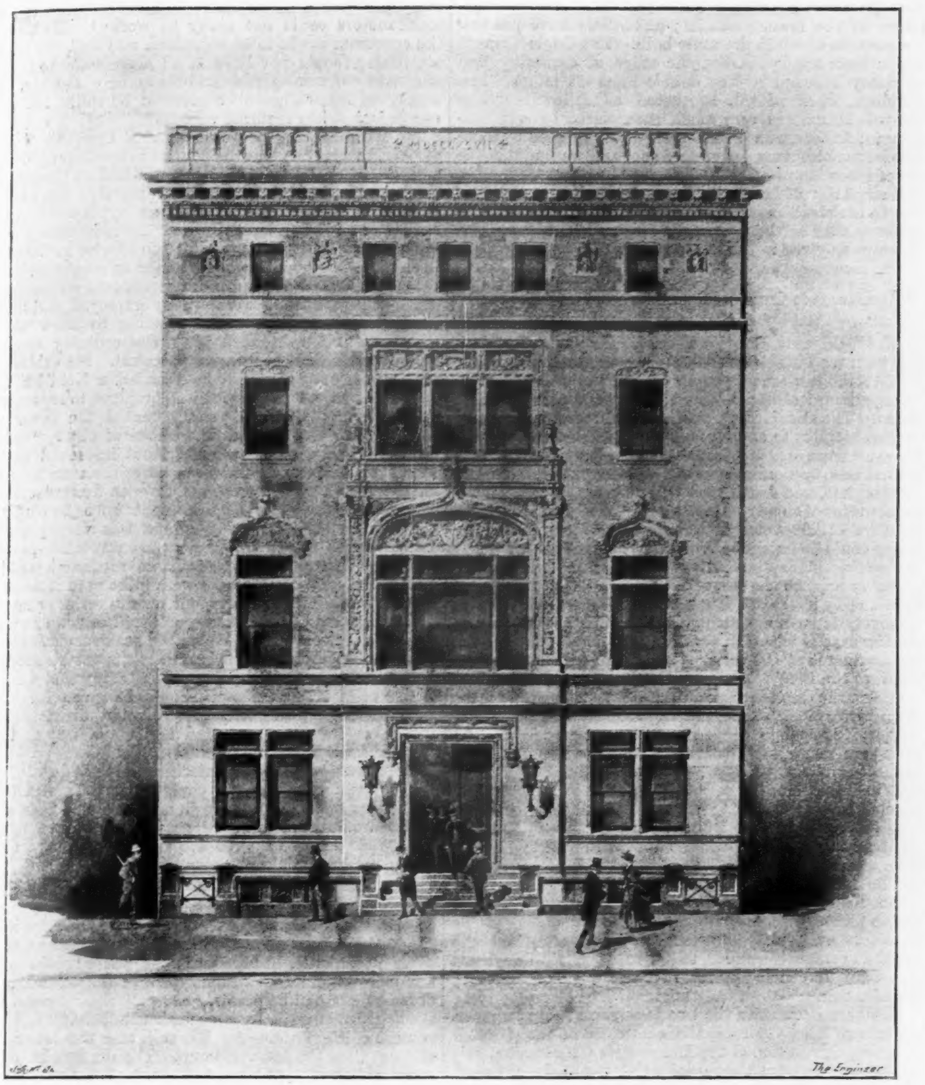
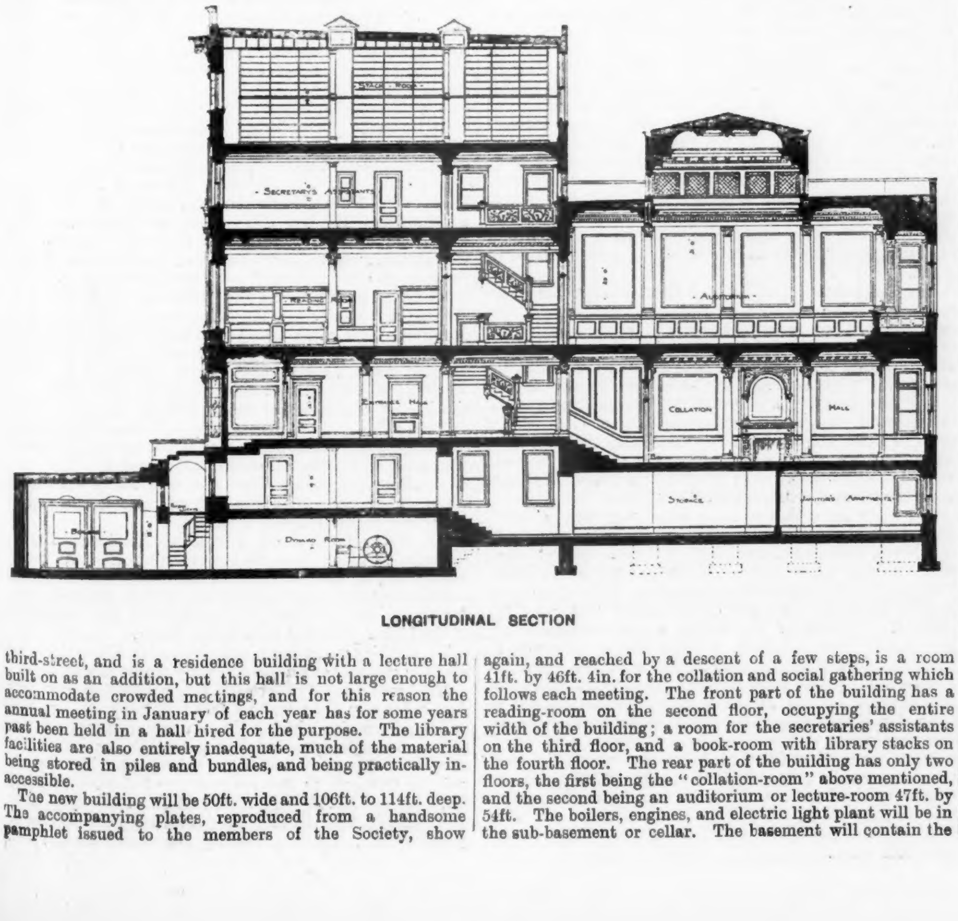
KING'S COLLEGE ENGINEERING SOCIETY.—At the last meeting Mr. Standen read a paper on "The Great Western Railway." The author commenced by a brief summary of its history, which was followed by a description of the first stage of the railway, Paddington to Bristol, all the important structures, such as the Wharncliffe Viaduct, the Maidenhead Bridge, and the Box Tunnel being referred to. He then gave a brief description of the works at Swindon, showing three types of engines on the screen. In the second division Mr. Standen dealt with the South Devon Railway, showing how Brunel constructed his line along the seashore, and explaining the atmospheric system as there used. This was followed by a description of the great bridge at Saltash, and an illustration of trestle work viaducts was shown. The author then dealt with the South Wales portion of the line, alluding to the "battle of the gauges," and the proposals for crossing the Severn. The Lydbrook and Crumlin Viaducts were described at this point, followed by the Chepstow Bridge over the Wye.

THE NEW HOME OF THE AMERICAN SOCIETY OF CIVIL ENGINEERS





LONGITUDINAL SECTION

NEW HOUSE FOR THE AMERICAN SOCIETY OF CIVIL ENGINEERS.

THE American Society of Civil Engineers, whose headquarters are in New York, has recently purchased a site and approved plans for a handsome new building on West Fifty-seventh-street, as it has long outgrown the capacity of its present building. The present building is on East Twenty-third-street, and is a residence building with a lecture hall built on as an addition, but this hall is not large enough to accommodate crowded meetings, and for this reason the annual meeting in January of each year has for some years past been held in a hall hired for the purpose. The library facilities are also entirely inadequate, much of the material being stored in piles and bundles, and being practically inaccessible.

The new building will be 50ft. wide and 106ft. to 114ft. deep. The accompanying plates, reproduced from a handsome pamphlet issued to the members of the Society, show the street elevation, and a longitudinal section. The main floor is raised a few steps above the street level. On the right of the vestibule and hall are the secretaries' rooms, while on the left are a reception-room and a coat-room. Beyond these is the main stairway hall, lighted from a narrow court on each side, while a toilet-room opens from one corner and the coat-room from another. Beyond this again, and reached by a descent of a few steps, is a room 41ft. by 46ft. 4in. for the collation and social gathering which follows each meeting. The front part of the building has a reading-room on the second floor, occupying the entire width of the building; a room for the secretaries' assistants on the third floor, and a book-room with library stacks on the fourth floor. The rear part of the building has only two floors, the first being the "collation-room" above mentioned, and the second being an auditorium or lecture-room 47ft. by 54ft. The boilers, engines, and electric light plant will be in the sub-basement or cellar. The basement will contain the janitor's rooms, and also ample accommodation for storing books, records, stereotype plates, &c.

The architect is Mr. G. L. W. Eidlitz, whose plans were accepted from among twelve sets of competitive plans. The site cost £16,000, and the estimated cost of the new house is £18,000 for the building and £2000 for furnishing.

THE CONVENTION OF THE MUNICIPAL ELECTRICAL ASSOCIATION.

AFTER the delivery of the presidential address, which we published last week, the business of reading the papers and discussing them was proceeded with. We were glad to find that each author only read a very brief summary of his paper, it being taken for granted that all members had had time to read the advance proofs.

The first paper was by Mr. A. S. Barnard, the borough electrical engineer of Hull, and the subject was

"ELECTRICITY SUPPLY AT 220 VOLTS."

We have not space to reproduce the paper verbatim, but shall summarise the chief points. The author pointed out that nearly all systems include networks of distributing mains, maintained at about the same pressure as required by the lamps on the consumer's premises; he, therefore, dealt chiefly with the advantages and disadvantages of the use of 220 volts on the distributing mains, without dealing with the vexed question of supply. It should, in the first place, be remembered that it is not to the much-discussed new regulations of the Board of Trade that we owe the beginning of a new era, in which 200 to 220 volts will be the accepted standard of pressure for incandescent lamps, as 100 to 110 volts is at present. The regulations did not produce the lamp, but it naturally followed that as engineers were considering the advisability of adopting the higher potential, that they should have been anxious to secure liberal clauses in these regulations, which should allow the use of 220 volts on the three-wire system, involving 440 volts between the outer cables. In the end they were mainly successful, but there are qualifications and conditions which will, in some cases, prove almost insuperable difficulties in the way of changing over an existing system.

Whatever doubts exist as to the benefits to the consumer of the higher voltage, there can be no question of the immense gain to the supply works by its adoption. In the first place, should the Westinghouse Company succeed in its application for a renewal of the three-wire patent, some stations having three wire networks at 110 volts may find it worth while to discard their middle wire and adopt a two-wire 220-volt system rather than continue to pay royalties on their mains. Briefly the advantages of the change will be as follows:—(1) Existing mains can supply twice as many customers, at the same time reducing the percentage of loss in the cables by one half. (2) Variations and fluctuations due to the switching on or off of motors or large groups of lamps, or carelessness in switching dynamos in or out at the station, are all reduced by at least one-half. (3) New customers can be supplied at a much greater distance from the station. After a station has been in operation two or three years the mains are usually overcrowded, and as electric light becomes more and more regarded as a necessity and not a luxury, this matter will entail very heavy expenditure. It was thought that the same end would be attained by the use of 110-volt lamps, which should take half the current which they now do for a given light. At present the most efficient 110-volt lamps take 2½ watts per candle-power, and the best 220-volt lamps in the market about 3½ watts, that is to say, the 220-volt lamps will consume about 40 per cent. more current than the high efficiency 110-volt lamps. Most people, however, prefer the 3 to 3½ watt lamps, which last longer and do not cause the annoyance of burning out so rapidly. No complaints of the 220-volt lamps have been received in Hull, where a number is in use. The author thinks 2½ watts per candle-power lamps will soon be produced for 220 volts.

Passing to the second point, the reduced variation of pressure, the author gives numerical examples, showing that if a person has a motor now worked at 100 volts, it will, of course, take only half the current if supplied at 200 volts. At starting it may cause a "jump" in the neighbouring lights of perhaps 4 per cent. of the pressure, but on the higher potential this will only cause a flicker due to 1 per cent. drop. Then there is the "coefficient of personal error," which makes itself felt if an attendant switches a machine in parallel with others, at say, 3 per cent. to 5 per cent. above the normal pressure. This error would be reduced to one half on the higher potential of, say, 200 or 220 volts.

With regard to the third point mentioned, the advantages to be derived are very obvious. A station distributing at 110 volts on a three-wire system can supply an area of about one square mile, or, say, an area of half a mile radius. Beyond this distance the cost of the heavy feeders and distributing mains is almost prohibitory, and the point is soon reached where it pays better to adopt a high tension system with transformers. To what distance it is possible to supply economically at 220 volts can hardly be said to be settled yet. Mr. Addenbrooke, in his recent paper before the Institute of Electrical Engineers, claimed that a 220-volt three-wire system could cover an area of 25 square miles from one station. As regards improvement in regulation, if the present condition of things in most towns, having a supply over an area of about one square mile from one station, be the best obtainable at 110 volts, it would seem that too much loss has been allowed in the distributing mains, and the error should not be repeated when the area is being extended. The author would not care to recommend the attempt to supply much more than four square miles from one station or sub-station, and this could be done in the case of many existing stations by doubling the pressure, using mains, which cost little over half as much as the mains laid in the business parts of the town, and yet reducing the loss and variation of pressure at the lamps to half the percentage obtaining at present. The new area would not, of course, be nearly equal to the present area in the number of lamps connected per yard of mains laid, and whatever basis be taken for calculating the sizes of mains in the business part, it should be quite safe to take two-thirds or even half of that figure as the basis for mains laid in streets of villas, private houses, &c.

At Bradford, as stated by Mr. Gibbings, the new station is designed to supply an area of about nine square miles on the three-wire system with 230-volt lamps. Districts at a greater distance, in an area of about seventeen square miles, will be supplied from the same station by means of motor transformers. This arrangement is practically the same as that recommended by the author for Hull.

For new stations, of course, capital outlay on mains can be largely saved. The author considers that installations designed for 100 or 110 volts pressure when changed over to 220 volts, run very little, if any, extra risk; the reduction in current quite balances the objection to the pressure being doubled. Certain little American switches, which are largely in use at Hull, get perceptibly warm with a 32-candle power 110-volt lamp, but keep quite cool and sparkless with a 220-volt lamp of the same candle-power. The author considers that with attention to the details of fittings, such as fuses, switches, and ceiling roses, wiring at 220 volts will be just as cheap and rather safer than at 120 volts. One difficulty, however, is with consumers who wish to use single arc lamps or to be able to switch off arc lamps separately, a man will do without a lamp rather than be obliged to have four lamps in series. Perhaps it may be possible to arrange a set of four very small arcs in series in one globe. For street lighting the 440 volts will be a distinct advantage. With respect to incandescent lamps, one firm has brought out an adapter by which two 8-candle power are used in series instead of one 16-candle power at the lower potential; and others have put two filaments in series in the same bulb. The single filament lamps have hardly reached the stage of durability and efficiency attained by the double filament lamps. Mr. Gibbings, of Bradford, is quoted as follows:—"The 230-volt lamps are very much appreciated by our consumers; in fact, we are continually being pressed by those who have not changed over to do so, and we find that the life of these lamps comes out if anything better than the ordinary 115-volt lamps." The author thinks that this is due to the steadier pressure supplied rather than to the better quality of the lamps. We reproduce illustrations of lamps as given in the above paper.

The second paper,

"Alternating Current Stations and High Voltage Lamps,"

by H. W. Couzens, Borough Electrical Engineer, Taunton, was then read in short abstract. The author remarks that it is to the low-tension engineer that we owe the high-voltage lamp, although this appears a contradiction in terms. The standard practice for high tension alternate current work is to employ transformer sub-stations, with a low-pressure distribution to consumers; but this hitherto has not been economically practicable in scattered residential districts, and distributed transformers have been the usual means of supply. He points out that with a declared pressure of 200 volts at the consumers' terminals, the mains could be extended four times as far each way, and the saving in capital outlay on the transformers will probably balance the cost of the low-tension network, and the stand-by losses of a number of small transformers with relatively large magnetising currents will be wiped out. A rarer case is where sub-stations are employed and the distribution is at 100 volts. On the two-wire system the pressure can then be easily doubled.

Where the distribution from the sub-stations is on the three-wire system at present, the 200-volt lamp is still of service. Straggling consumers may be picked up, and there are many installations which it would pay to connect at 200 volts although not at 100 volts. Reduction in initial cost is of great importance, and can be effected by this change. At present all the demands for high voltage lamps are from the direct-current stations, and alternate-current engineers appear to have taken very little interest in the matter. The new Stearn M-shaped double filament lamp gives a useful and pretty effect when lighted, and the 8-candle power lamp is also a success, though the importance of this size of lamp is, he considers, over-rated at present, for it is very difficult to get the average consumer to be satisfied with anything less than 16-candle power in these days of increased illumination.

The discussion upon the two papers was taken together. Alderman Higginbottom, the chairman of the Electric Lighting Committee of the Manchester Corporation, said he rose to represent the ratepayer's view of the question. He believed if such a body as the Municipal Electrical Association had been in existence at the time of the Board of Trade Conference in Westminster, that a number of points could have been settled. The President, in his address, had raised a question as to the advisability of having separate committees to deal with particular points, the speaker thought joint committees were best. In Manchester the Electric Lighting Committee does not touch the streets. Is it right to build up a large reserve fund out of the ratepayers' money, and not to reduce the price of the current? Of course, a renewals account is very necessary, but in Manchester after 5 per cent. profit had been made, it was necessary to reduce the price of the current. A contingent fund was permitted up to 10 per cent. of the total capital, and after that, profits must be distributed in some way. Should municipal buildings be charged less than ordinary buildings? He thought not, and they were not so charged in his city. Then as to income-tax. Why should they be obliged to pay when the profit was made by the city for the ratepayers? A municipal electric light station should not be a sort of training school whence their engineers should pass to other towns, and in order to retain their officials good salaries and adequate bonuses should be given.

The Chairman of the Bedford Electric Lighting Committee gave an account of the work in Bedford, and said they had had great difficulties to contend with, but they made a profit last year of £90, all costs included except paying back the instalment of loan and interest—the period within which the loan was repayable was twenty-five years. The committee had had applications for reduced charges for Sunday lighting of chapels and churches, and they were now considering the question, which was one of some difficulty. He thought it would be well if representatives of corporations could have seats upon the Council of the Association.

Mr. Jackson said the lamp efficiency was a most important matter, and should be carefully considered. A 100-volt lamp was more efficient than a 200-volt lamp and a 50-volt lamp more efficient than a 100-volt lamp. The gas industry was now endeavouring to compete more keenly, and the price per candle-power was very important. He believed Mr. Stearn, a lamp manufacturer, had stated that the high voltage lamps were not so economical to the consumer as those of 100 volts. A 4 or 5-candle power lamp was not possible at 200 volts. The question should be taken up by the Association, as the value of the different types of incandescent lamps was very important.

Mr. Carson thought that 220 volts would be very advantageous for outlying districts. If the Westinghouse Company obtained a renewal of the three-wire system patents it would be a bad thing for the supply companies, and payment could be avoided by putting lamps across the outer wires.

Mr. Rider, of Plymouth, was amused to see the low-pressure engineers going in for high-pressure so eagerly; it seemed as though they were following the alternate current system as much as possible. If 220 volts were used the consumer with a single arc lamp must be given up, and small motors could not easily be worked. He thought the consumer ought to be consulted, and that the supply companies should not have it all their own way. The alternate current system was extremely flexible, and supply to houses could be given at 50 volts, 100 volts, and in fact at any required voltage.

Mr. Wordingham, the City Electrical Engineer of Manchester, said his city was the pioneer in the use of 400 volts, and the fact of the use of that potential had led the Board of Trade to raise their standard of low-pressure. They had no difficulty in the supply as yet, although very few of their customers had 200 volt lamps in use. He must utter a warning as to the wiring; it would not do to wire for 200 volts in the jerry way which was now so often employed for 100 volts he had made a number of experiments with ordinary china fittings, such as were usually employed, and he had brought the remains to the meeting to show to the members. He contended that the ordinary crockery would not stand the increased potential. He exhibited a single pole cut-out which had carried a No. 30 S.W.G. tin wire, and he had put on 60 ampères to represent a short circuit; with 200-volts potential the cover was broken. He also showed a number of other "relics," proving clearly, as he thought, that improved fittings would be necessary. In some cases the terminals and all the metal work were fused into an irregular mass. The point which had been brought up as to single arc lamps and 8-candle power lamps was very plausible. The five-wire system in Manchester was a low-pressure system, and gave 100 volts, and two arc lamps could be used in series. If 220 volts were to be used it need not become a question of using four arcs in series or none at all, for it was obvious a great number of consumers would object to use four arcs. He should get over the difficulty by putting in a pair of balancing direct-current transformers across the mains, and he was now advising that a supply of 200 volts or thereabouts should be given for purely incandescent lighting in the residential districts. The apparatus should be arranged in such a way as to be suitable for a given pressure.

Mr. Stearn, a lamp manufacturer, rose and stated that the opposition to the movement in favour of 220-volt lamps was gradually dying away. There had been a few short circuits, but precautions must be taken against risks. He believed the relative risks in the case of the three best-known illuminants were:—

Electricity.	Gas.	Oil.
1	10	40

So that they could very well allow for a slight rise in the risk without even then approaching to the risks of the other illuminants. There was no reason why the use of a higher potential should necessitate the abandonment of lamps of 8-candle power. He entirely disagreed with the suggestion made by one speaker that the 50-volt lamp is more efficient than the 100-volt, and the latter more efficient than the 220-volt lamp. The diminution of the cross section of the filament does not affect the life of the lamp. Filaments of 2 mils. diameter last as long as those of 50-volts, but of course if the cross section is decreased and the filament made abnormally long, it must have some mechanical support. There was no need to abandon either the 8-candle power or even the 5-candle power. Lamps of high efficiency had been strongly advocated by the speaker, but, as a matter of fact, the bulk of those in use consumed from 3·7 to 3·9 watts per candle-power. An 8-candle power lamp at 3·7 watts per candle-power and 200 volts pressure lasts well and is quite satisfactory; for 10-candle power and 16-candle power lamps an efficiency of 3·0 to 3·2 watts per candle-power could be obtained at 200 volts. He thought it was undesirable to attempt too high efficiencies at first, they should begin with lamps which would give perfect satisfaction. For pressures of 200 to 230 volts 16-candle power lamps could be made to take from 3·2 to 3·3 watts only, and these were now obtainable, but engineers should begin with lower efficiencies at first.

Mr. Gibbings, the Borough Electrical Engineer of Bradford, said that the arc lamp question was, of course, a difficulty. He had 379 private arc lamps upon his mains, and he had just ordered a special machine, and was about to use a third wire so as to be able to balance the load on each side, and keep two arc lamps in series between the third wire and the mains carrying the 230 volts. He had carefully tested the efficiency of 220-volt lamps constantly in the last two years, and found that at first they gave 1-candle power for 3·7 to 3·8 watts, and after burning from 2000 to 3000 hours they still gave an efficiency of 3·5 watts per nominal candle-power, although the actual candle-power had fallen to one-half of its original value. He would be able to discuss this portion of the question much better a year hence, as he now had 385 consumers using 230-volt lamps, many of them being of small candle-power. The fact was, many customers asked to be put on to the 230-volt circuit, instead of remaining on the 115-volt circuit.

Mr. Stewart, Borough Electrical Engineer, Derby, remarked that he thought the explanation of the statement made by the last speaker, as to the preference of consumers for 230-volt supply, rather than 115 volts, was due to the fact that the meters registered less accurately at the higher potential than at the lower.

Mr. Gibbings, Bradford, replying to Mr. Stewart, stated that the meters read quite correctly with 230 volts.

Mr. Arnot, the City Electrical Engineer of Glasgow, said that in his city they had no 200-volt lamps in use yet, and the discussion which had now arisen as to the relative efficiencies of lamps of various potentials, reminded him of what a Glasgow doctor told him about Mr. Swan's visit to Glasgow in the early days of electric lighting. Mr. Swan exhibited his lamps, and the same objections were brought forward and difficulties raised as were now brought forward about the high-pressure lamps, and he—Mr. Arnot—had no doubt all these points would soon be surmounted. He believed the 200-volt lamps would be chiefly used in the future, and that the consumption of energy will be materially less than 4 watts per candle. The same discussions had taken place as to the relative economies of high and low-pressures to steam boilers, and he believed that pressures of 300 lb. per square inch were now being used. Sir Courtenay Boyle would doubtless see that the regulations of the Board of Trade precluded the possibility of such results as those shown by Mr. Wordingham in his samples. He should be very glad to see all the crockery which was now scattered about the house cleared off the walls, and put in some safe places. It was no good arguing as to the relative advantages of high pressure or low pressure, alternating or direct current *per se*, each was best for certain districts, and it was for the electrical engineer to decide which system was best suited to his own particular case.

Mr. Barnard then replied, and said he was glad to hear from Mr. Stearn that the opposition to the use of 220-volt lamps was dying away, and that lamps of small candle power could be produced. In Hull he proposed to use motor transformers. In Bradford it had been stated that only 180 eight-candle power lamps were in use. Upon this point we would remark that, from his own personal experience, he felt sure central station engineers are greatly deceived as to the number of low candle-power lamps in use on their circuits. If practice in the provinces at all resembles that in the metropolis, it is quite a common thing for the whole of the lamps in a house to be stipulated as 16-candle power in the specification; this is, of course, done so that there may be no dispute about the size of the wires, every lamp being wired as though for 16-candle power. The application forms are, we know, often filled up from the specification long before the wiring of the house is completed, and we believe it is on these application forms that station engineers rely for their data. The figures obtained from such forms are, however, entirely untrustworthy, as in many houses the bulk of the lamps are 8-candle power; in fact, it is a common thing for a consulting engineer to instruct the contractor to put in 8-candle power lamps throughout, and substitute 16-candle power lamps afterwards in case the consumer complains that he gets insufficient light. With respect to "crockery" being scattered about the house, we suppose Mr. Arnot meant cut-outs, and though this practice may still exist in Glasgow, it is very rarely met with in London. Distribution boards in proper glazed cases are the rule and not the exception.

Mr. Couzens then replied, and said that consumers buy lamps of 3·5 watts per candle-power, and like a lamp with a long life. He had made a number of experiments similar to those carried out by Mr. Wordingham, and had put a farthing into a lamp holder instead of the lamp so as to cause a short circuit; the results, however, were not like those obtained by Mr. Wordingham; in fact, the porcelain suffered no injury. He presumed that this was due to the fact that the alternate current arc did not persist so long as that produced by direct current.

In our next impression we shall conclude our report of the proceedings.

THE NUMBER OF PERSONS EMPLOYED IN COAL PRODUCTION in various countries in 1894 was as follows:—United Kingdom, 665,747; Germany, 299,627; Belgium, 117,103; France, 131,587; Japan (1893), 30,345; the United States (1893), 363,309; British India, 43,197; Canada, 9654; New South Wales, 9131; New Zealand, 1899; and the Cape, 1601.

GAS ENGINES IN ELECTRIC LIGHT STATIONS.—Considerable interest attaches to the statements of accounts of the Belfast electric supplyconcern, recently published. A total of 95,126 units have been generated, with a total consumption of 4,454,667 cubic feet of fuel gas from the town mains, or 46·8 cubic feet per unit generated. The price paid for gas was 2s. 3d. per 1000 cubic feet, or 1·26d. per unit generated. Of the total amount generated, 82,197 units were sold during the hours when the charge is 7d. per unit, and 574 units in the time when 4d. per unit was charged, this is 87 per cent.; and deducting from the remainder the 3822 units used on the works for lighting, starting the engines, &c., the residue represents a loss of only 9 per cent. of the total generated. The energy wasted in the batteries has been 6304 units, and in the mains 2229 units, figures which correspond respectively to 6·7 per cent. and 2·3 per cent. of the total generated. Accordingly, the consumption of fuel gas per unit sold has been 53·7 cubic feet, the cost of which has been 1·45d. The cost of lubricating oil, waste, circulating water and stores, was 0·202d. per unit generated, or 0·232d. per unit sold. It cannot be alleged that either of these figures is excessive. Higher figures are, the *Electrician* says, often reached in steam-driven stations. In fact, the total generating expenses have not exceeded 2·82d. per unit generated, or 3·24d. per unit sold, figures which are not unreasonably large for a station of the size of that at Belfast.

THE LONDON WATER SUPPLY.—In giving evidence before the Hybrid Committee of the House of Commons engaged in the consideration of the London Water Companies' Bills on Wednesday, Sir J. Pease presiding, Mr. R. E. Middleton, M. Inst. C.E., recalled, said that, inclusive of the powers already possessed by the water companies, they would, under the Bill, be able to take 149,000,000 gallons of water per day from the Thames. As the Bill stood, the three companies who were party to it would be able to take 100,000,000 gallons a day from the Thames so long as the flow over Bell Weir was not reduced below 250,000,000 gallons, and what they did not use of the water they so took they could sell to other water companies. They had no intention of doing anything of the kind, but no doubt the joint committee would be the first mortgagees of the water coming over the Bell Weir over 250,000,000 gallons per day. The case of the Conservators of the river Thames, who were opponents of the Bill, was afterwards proceeded with. Mr. C. H. Moore, engineer to the Conservators, declared that the six London water companies had power to take 130,000,000 gallons of water from the Thames per day, but as a matter of fact on single days they had exceeded that amount by 10,000,000 gallons—a serious thing when they bore in mind that the flow of the river had sunk on a certain day in 1877 to 180,000,000 gallons. He thought the companies should not be allowed to increase the amount of their daily intake from the river. Mr. Fitzgerald addressed the committee on behalf of the Thames Conservators, insisting that the companies should not be allowed to sell the surplus water taken from the Thames to other companies, and that whatever fresh water they took they should pay for at the same rate as they paid for their present intake. The case of the London County Council was then submitted. Mr. Dickinson, chairman of the Water Committee, and formerly deputy-chairman of the Council, who was the first witness, gave a history of the London water question, and declared that the scheme of the present Bill, if passed, would prejudice the settlement of that question in the future.

THE MANUFACTURE OF STERILISED BUTTER.

THERE is probably no industry in which this country has been so far outstripped in the race of progress by foreign ingenuity as that of butter-making, and it behoves our dairy farmers to look around them, if they would desire to win back for our own home trade some part of the thirteen or fourteen millions sterling which annually finds its way on to the Continent and to our Colonies for the purchase of butter. Dairymen, even in this country, have for some time past become alive to the necessity of employing what may be termed up-to-date appliances, and we now see those beautiful examples of mechanical ingenuity for separating cream from the milk by centrifugal force almost universally employed. That these appliances are almost solely due to the inventive genius of our continental friends cannot be seriously disputed; and while, on the one hand, this is a matter for regret, on the other it is some satisfaction to know that the net result has been to place this important industry on a far surer and more scientific basis.

Ever since it has become generally recognised that one of the most essential factors in preserving health is the purity of food, scientists have turned their attention largely towards the sterilisation of foods which are generally consumed uncooked. Milk usually undergoes this process before consumption, but butter has baffled ingenuity to devise some method of freeing it from its microbes, which are equally as detrimental to health as those contained in milk. The reason for this is that butter cannot be raised to the required heat, *i.e.*, 160 deg. Fah., for destroying its microbes, without ceasing to be palatable; and it has again fallen to the lot of a Swedish gentleman, Mr. Gustaf Salenius, to sterilise, or, as it is termed on the Continent, "pasteurise" butter by means of a machine which he has invented, and which has for some time been at work with perfectly satisfactory results in Sweden. To this appliance the inventor has given the name of "Radiator," from which it will at once be surmised that centrifugal force again plays an important part in the process. The advantages claimed for pasteurised butter are two-fold: It is conducive to the preservation of health, and its keeping qualities are greatly increased, the latter being a consideration of the greatest importance to the dairy farmer. The chief considerations which Mr. Salenius has had in view in designing his butter-maker are as follows:—First, the production of a very fine, uniform butter, with great keeping qualities; secondly, the importance of obtaining the largest possible yield of butter or cream from the milk; thirdly, the convenience of installation of the machinery in a small space, and facility of management, together with simplicity of the parts and ease of removing and cleaning them; and fourthly reduction in the number of dairy hands required.

Fig. 1 herewith represents a sectional elevation of the "Radiator" butter-maker, and Fig. 2 on page 616 is a photographic reproduction of a complete plant for producing pasteurised butter, which was shown at work at the recent Bath and West of England Agricultural Show. Briefly, the machine consists of a cast iron stand A, a skimming bowl N, churning chamber R, and three tin-plate covers introduced one into the other. The stand comprises a flat base connected with the body, holding the skimming bowl by two uprights, one of which supports the bracket B. The two legs are connected by three crosspieces D, E, K, provided with brass bushes. In the lowest crosspiece D, a footstep bearing is provided for supporting the driving spindle F, with its pulley G. This spindle F is connected with the bowl spindle L by a coupling H, and the bowl spindle passes up through the cast iron body containing the skimming vessel, being supported on ball bearings M, which are kept thoroughly lubricated by the oil tube shown. On the top of the spindle L is a collar which carries the bowl N, and the top of the said spindle is turned up to a cone shape, and fits into a hole drilled in the whole milk distributing basin. Above this cone is placed the inlet cone or pillar S, open at both ends, and through the top of which the whole-milk enters. The upper open end T of this pillar constitutes the cold water distributing cup, the water being conducted to it by a pipe X, surrounding the whole-milk inlet tube V, while wings provided on the pillar support a number of step-shaped cooling plates P. The wall of the cold water distributing cup T is pierced by six holes *l*, to which are fitted an equal number of tubular cooling frames U, placed all round the inside of the churning bowl R. After passing through these the water falls into the cold water receiver *i*, from which it is led away by means of a spout. The churning bowl is fixed on the skimming bowl N by means of a special joint shown. The skim milk is discharged from the chamber N into the receiver *k* by means of six small bent tubes *n*, and from this receiver it is again discharged by the spout *q*. The cream passes up into the churning chamber through an opening *m* in the bottom, and spreads itself in a thin layer on the surfaces of the coolers U, where its temperature is rapidly reduced to that suitable for churning operations.

The churning tube Y is provided with a handle shown, so that the sharp-edged mouthpiece at its lower end may be brought into or thrown out of contact with the layer of cream. When in contact the cream enters with some force into the churning tube, where it is subjected to repeated concussions, which cause agglomeration of the butyrous globules in suspension. It is then passed out of the tube by way of a number of small holes about $\frac{1}{16}$ in. diameter, and being violently projected in fine sprays against the layer of cream produces butter, which rises and passes in a granular form through openings at the upper edge of the chamber into the receiver *g*, where automatically operated scrapers *h* collect the produce and drive it out of the spout *p*. By throwing the mouthpiece of the churning tube out of contact with the layer of cream by means of the handle above mentioned the cream escapes unchurned through the same spout. It will thus be seen that the radiator can be utilised either simply as a cream separator or simultaneously as a separator and churn. *b* is the colour feed apparatus, *c* the thermometer,

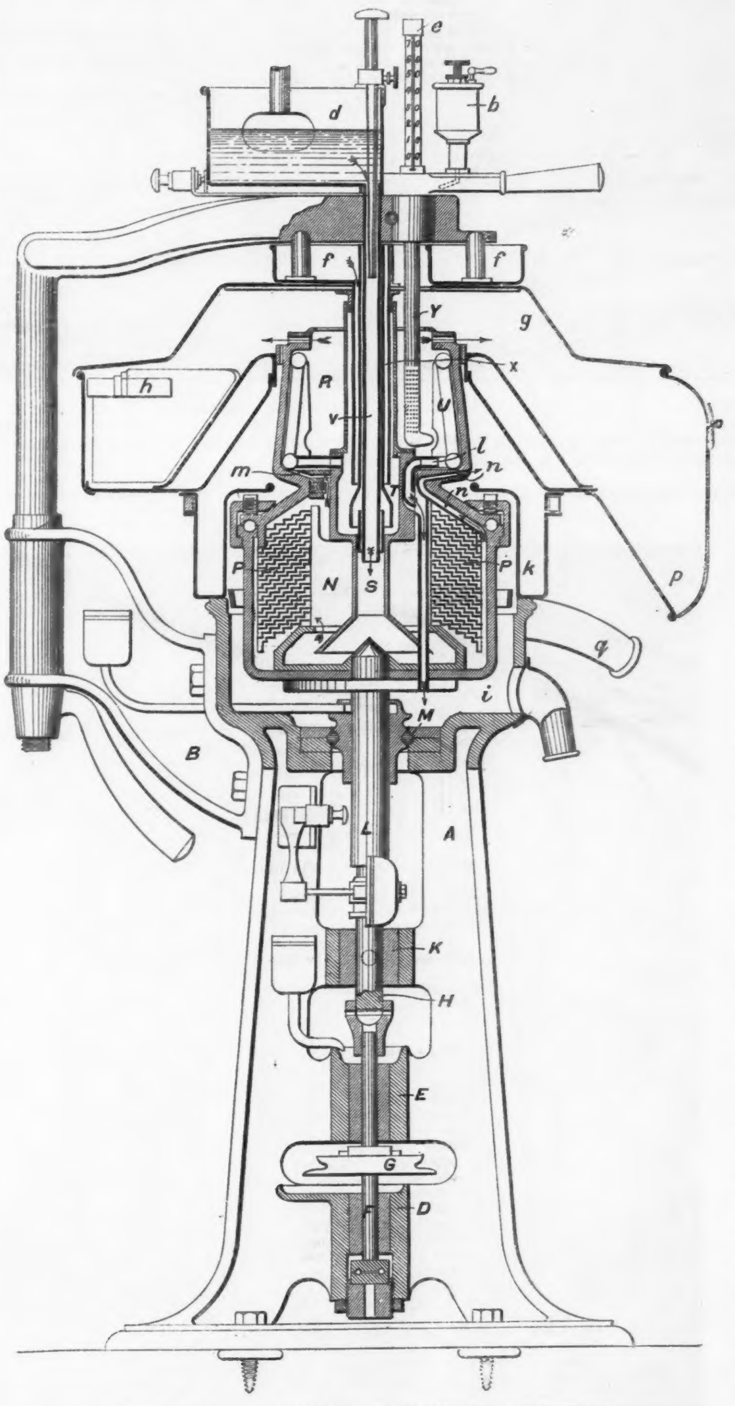

Fig. 1—SECTIONAL ELEVATION OF RADIATOR BUTTER-MAKER

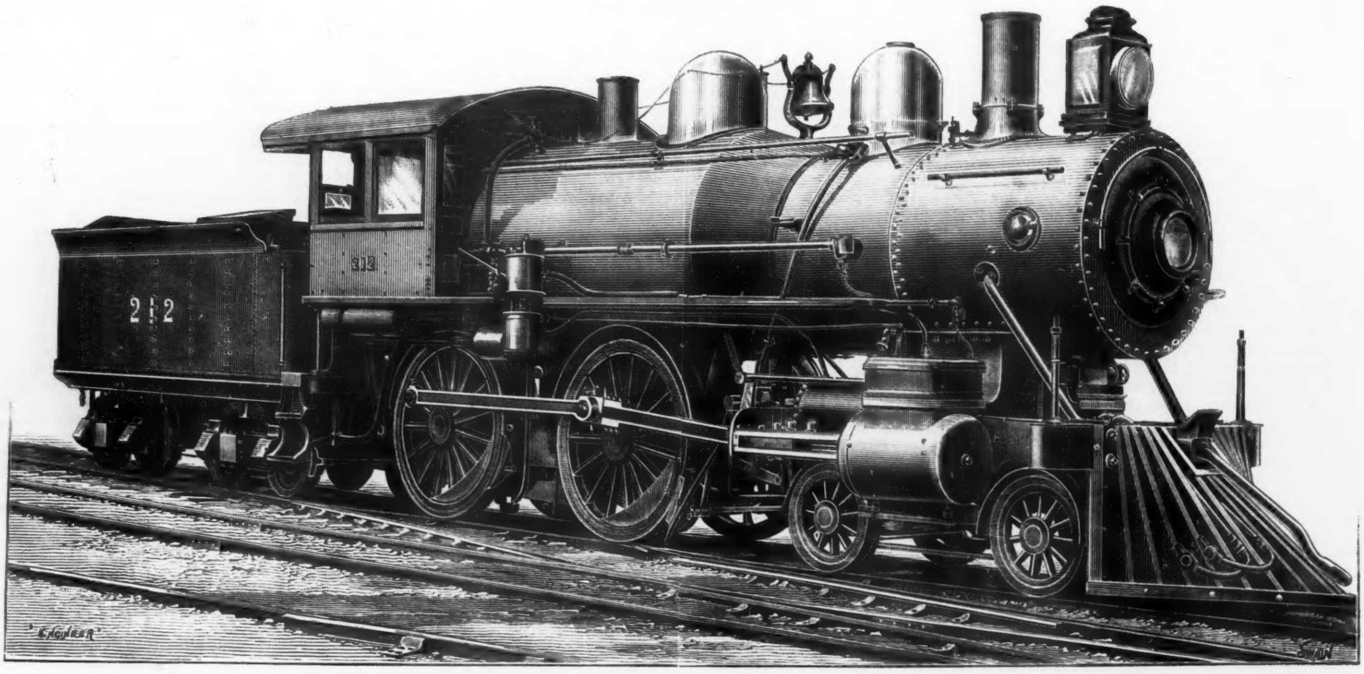
EXPRESS LOCOMOTIVE, BOSTON AND ALBANY RAILROAD, U.S.

(*For description see page* 622)



and *d* the whole milk inlet trough wherein is collected the milk as it comes from the pasteuriser, while *f* is the cold water inlet trough.

Fig 2, as above stated, represents a complete plant for making pasteurised butter, the radiator being shown in the foreground, while on the stand behind it is the pasteurising tank W, in which the whole milk is heated up to the desired temperature, *i.e.*, 160 deg. Fah., before being admitted into the top of the radiator. Behind this tank W is the water tank X^1, from which the cold water jackets are fed by a centrifugal pump. The skim milk from the radiator is discharged into the tun dish shown, and is forced by another centrifugal pump through the pipe X^3 into the cooler X^2. When the milk in the pasteuriser has reached the temperature of 160 deg., and the radiator, after being started, has attained the speed of 6000 revolutions, shown by a speed indicator, the supply cocks for the cooling water and whole milk are opened; one minute after that, the granular butter, impregnated with its buttermilk, issues from the butter spout, and is collected in an open butter tub. It is easy during the working to vary the consistency of the cream by adjusting the whole-milk feed inlet, as well as to maintain unchanged the desired churning temperature, by increasing or reducing the water supply to the tubular frames in the churning bowl. Although in the drawing the radiator has a somewhat complex appearance, it is comparatively simple in construction, and can easily be taken to pieces for cleaning, while the plant required for driving a complete pasteurised butter apparatus capable of treating 200 gallons of milk per hour need only be sufficient to exert about four horse-power. This system of butter making has been extensively used in Sweden for about two years.

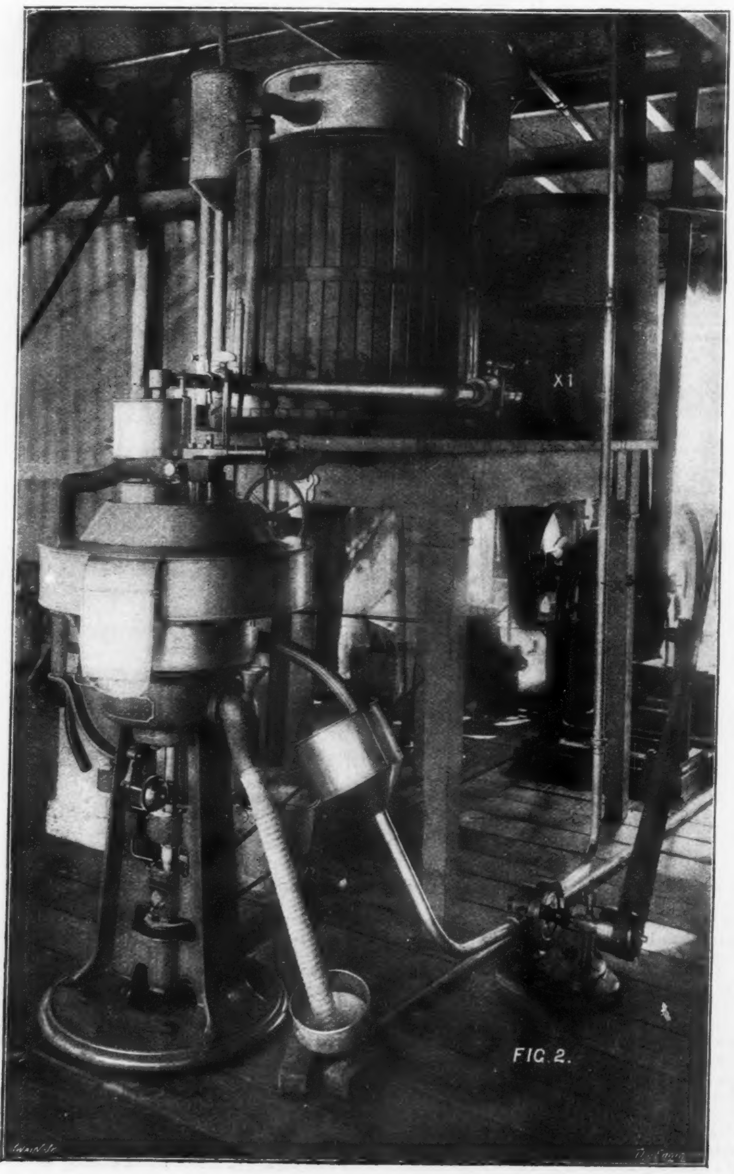


Fig. 2—STERILISED BUTTER-MAKING PLANT

The following is an abstract of a report to the Minister of Agriculture in Paris of trials of the radiator, made by MM. H. Friant and V. Houdet at the Practical Dairy School at Poligny in July last:—

"From a mechanical point of view the radiator is a very ingenious and perfectly constructed machine, which works with irreproachable regularity. In spite of the high speed with which it revolves, and the absence of any foundation, it works silently and without vibration. The mode of mounting it is most simple, and in every way within the reach of our dairy servants. Its starting presents no difficulty, the preparations and precautions are the same as for other centrifugals. From an industrial point of view the radiator indisputably offers important advantages. The space necessary for its installation is only a room 17ft. square, including space for accessory work. The labour is reduced to a minimum. Two persons, in fact, suffice for attending—one to the boiler and engine, the other to the radiator and its necessary appliances, dividing between them the butter working and the cleaning. The radiator can operate either simply as a cream separator, producing pasteurised cream, which can then be soured by addition of lactic ferments, or at all times of the running it can operate simultaneously as skimmer and churn. In the operation of cream separating, the degree of clean-skimming is as high as is practically possible. We do not know any centrifugal which, on this point, is superior to the radiator. The churning is as complete as possible, and does away with the anomalies incident to the souring of cream. In none of our comparative trials has the yield of butter by the radiator been exceeded by that of the procedure ordinarily used.

"The whole-milk is pasteurised, skimmed, and its cream churned while almost completely protected against contact with the air, a very favourable condition, which is not obtained with any other method of manufacture. During the running the pasteurised cream is instantly brought down to a suitable temperature, which is kept constant by regulating the admission of cold water. By this means one avoids the previous heating and cooling of the cream, and also the faults in the butter itself caused by the raising of the temperature, which invariably takes place when using ordinary churns. Not only is the work continuous, but one can control all its stages rapidly during running, within the following limits of temperature—from 85 deg. to 160 deg. for the skimming, and from 54 deg. to 68 deg. for the churning.

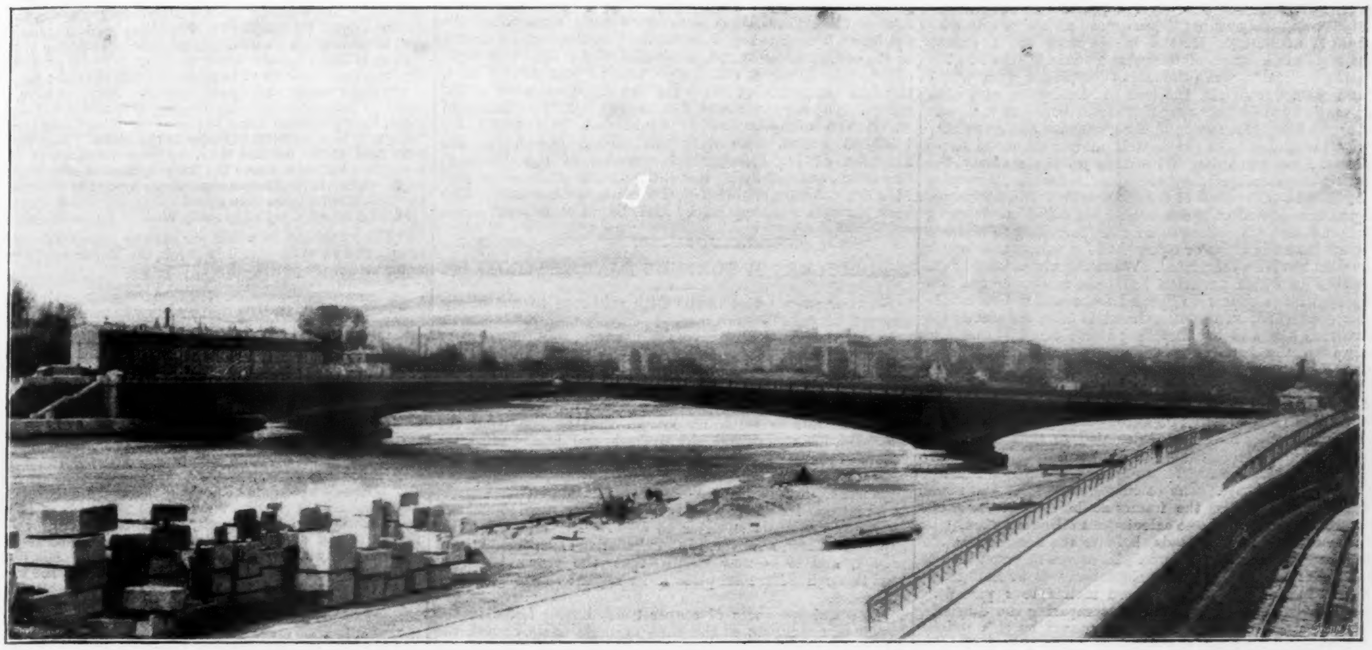
"As regards the quality, the butter leaves nothing to desire, although the cream has not been soured; it is, besides, rendered independent of any special skill on the part of the attendants. The butter is homogeneously plastic, fine, and of good consistency; has a fresh flavour, a delicate aroma, and, owing to the pasteurisation of milk, it has keeping properties which we have in all cases found superior to those of butter made by the usual processes, and a safety in being used as food all the more valuable, as butter, once produced, cannot be sterilised. In conclusion, the radiator gives, economically, excellent work, with a minimum of buildings, of implements, of labour, and of time. It has consequently its place indicated in dairies of some magnitude, notably in those which work for export."

The Société Nordenfelt, 8, Rue Auber, Paris, are the agents for this system as regards England and France.

THE BIRMINGHAM ASSOCIATION OF MECHANICAL ENGINEERS.—At the half-yearly meeting of the above Association, held on Saturday last, the following gentlemen were elected members of the Council:—Messrs. W. Greenup, C. Proctor, F. M. Martin, and W. Holt, vice Messrs. F. S. Green, W. H. Winn, W. Deakin, and Arnold. Mr. W. Arnold was elected auditor vice Mr. C. Hill. The President, Mr. C. Hazel, announced that arrangements had been made to visit Messrs. Siemens in July.

MASON COLLEGE, BIRMINGHAM.—From our advertisement columns it appears that Professor R. H. Smith has resigned his engineering professorship in Mason College. We learn that Professor Smith intends to devote his energies in future entirely to practical work. The restrictions placed upon the development of the engineering school in Birmingham have for some years inclined him to leave it, and the latest arrangement are such as he does not feel he can share the responsibility for. Nevertheless the school has had considerable success. The engineering students of Mason College supply 35 per cent. of the fee-income of the seven scientific departments of the College, and 21 per cent. of that of the fourteen science and art departments forming the whole College, while the engineering expenditure in proportion to income has been much below the average throughout the College. The school has attracted numerous pupils from every quarter of the globe, and a considerable portion of its past students are, we are informed, now in management of important works not only in England, but in many other countries. These students will hear with regret that their *alma mater* is now to pass under other management.

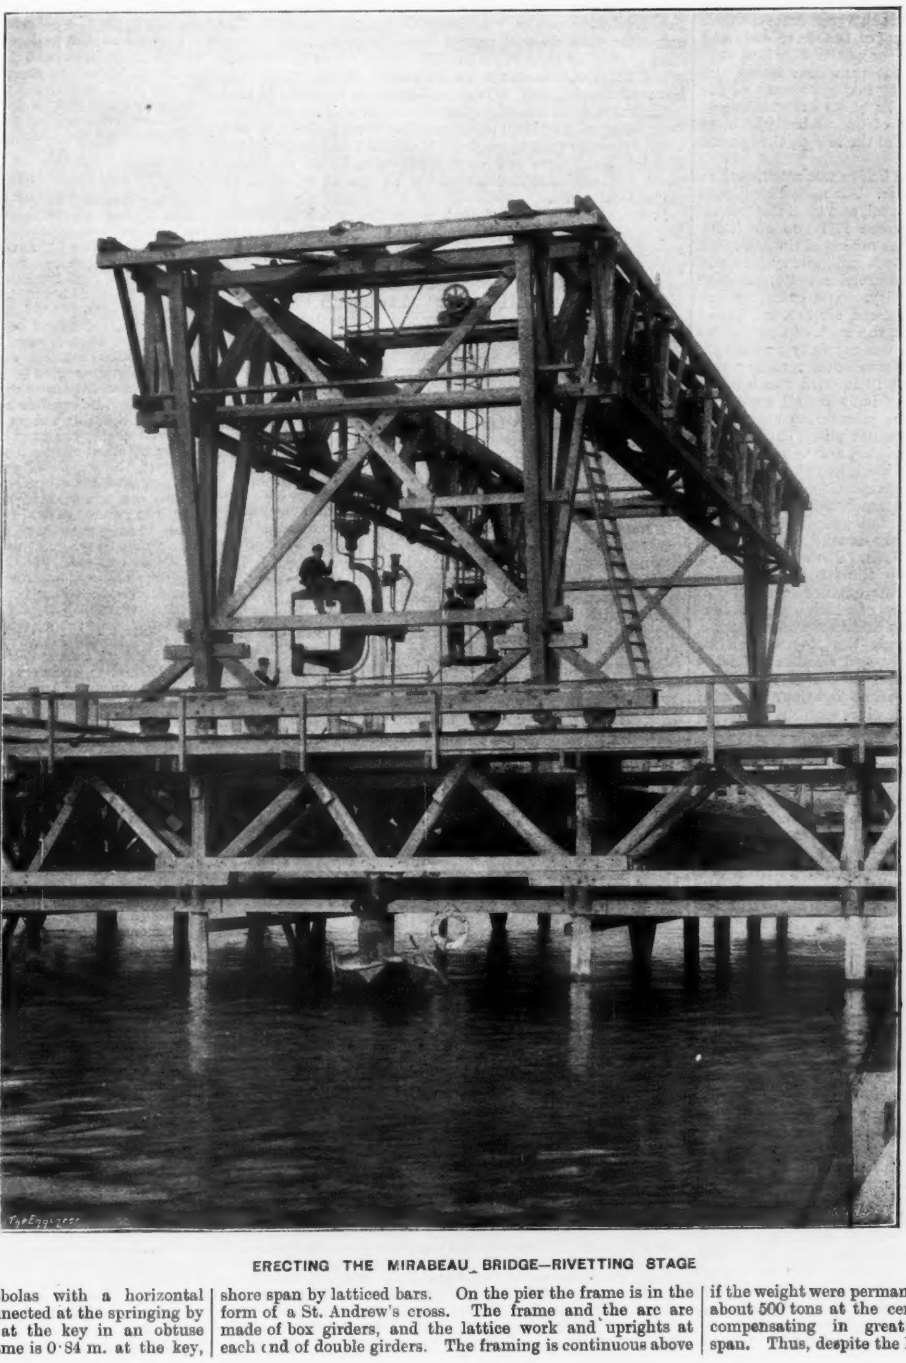
THE MIRABEAU BRIDGE OVER THE SEINE



THE MIRABEAU BRIDGE.

THE particulars we published in a recent issue of the Mirabeau Bridge, which has been constructed across the Seine in Paris to connect the districts of Javel and Auteuil, may be supplemented by details that are not without a certain interest. The main feature of this bridge is the novelty of its design, which has had to meet the special requirements of the traffic in the neighbourhood, both vehicular and water-borne. The conditions laid down were that the approaches to each end of the bridge were to be sufficiently easy to permit of the traffic crossing it without difficulty, at the same time that the structure did not cause any impediment to the passage of vessels. These have been carried out with entire success by the cantilever bridge designed by M. Résal, chief engineer of the Ponts et Chaussées. With a central span of 306ft. and two travées or arms of 106ft. 6in. each, measured between the masonry. The bridge has a width of 65ft. 8in. between the parapets, the roadway itself being 39ft. 5in. wide. The metallic superstructure rests upon two piers, which are founded on a stratum of hard chalk at a depth of 37ft. 4in. on the left and 36ft. on the right of the river. The masonry of the piers is built with Portland cement concrete set off with Cherbourg granite, while the abutment is constructed with hydraulic lime concrete. The superstructure is composed of seven rolled steel frames placed at distances of 3 m. from each other under the roadway and of 3·72 m. under the pavement. The cantilever is made of two equal halves resting upon the pivots and connected at the centre by an articulation, while they are fastened to the abutment by anchoring bolts. Each half river span has a length of 163ft., measured from the pier pivot to the key, and the culasse or shore span measures 122ft. 9in. from the pivot to the extremity. The height from the pier pivot to the centre of the bridge is 20ft. 3in.—see engravings on page 618. The upper part of the cantilever is rectilinear, with an inclination on the horizontal of 0·02 m. per metre. The lower part or the arc has the form of two semi-parabolas with a horizontal axis. These parabolic arcs are connected at the springing by rectilinear elements which meet at the key in an obtuse angle. The height of each half frame is 0·84 m. at the key, 0·50 m. at the end of the shore spans, and 5·35 m. on the piers. The top frames and the arc abut on the same frame at the two ends of the cantilever. At the key they are connected by vertical castings at distances of 2 m., and at the end of the shore span by latticed bars. On the pier the frame is in the form of a St. Andrew's cross. The frame and the arc are made of box girders, and the lattice work and uprights at each end of double girders. The framing is continuous above the pier, and the ends of the arcs are fixed on a steel pivot or balance. This balance is composed of two plates or tables on which the soles of the arcs are bolted, and a central piece with a double heel and collars which support the soles, while the combination rests by means of a half cylinder upon a steel cushion let into a cast iron bed in the granite. The articulation of the key is formed by means of a double series of steel pieces, some being merely plates riveted to the ends of the cantilevers, and the others male and female joints which bolt the cantilever together. The anchoring of the ends of the shore spans is effected by vertical rods, of which the upper parts are fixed in the box girder of the abutment, and the lower part to the trunnions fixed to the cast iron cushion which is fastened to the embankment by four bolts. These bolts pass within the thickness of the abutment and are anchored to an iron framework in the masonry. The pier beds and cushions of the culées are all fixed in cement. The frames are connected together at the level of the arc by latticed girders, by] sections at the right of the vertical uprights, and by girders forming part of the bridge at the upper part. The top of the shore spans is built up on brick vaults set with cement, and that of the river span is constructed of steel plates of 10 mm. in thickness riveted on to the frames. The roadway is paved with wood. The pavements on the shore ends are supported on plates strengthened by double girders let into a thick bed of concrete, and on the river span by plates riveted on to Zorè's sections. The space between the girders which connect the upper part of the frames and the plates supporting the pavement has been left free to permit of the laying down of water and gas pipes. The piers of the bridge are to be adorned by bronze figures, which have been modelled by M. Injalbert, and are now being turned out at the foundries of MM. Thiébaut Frères.

The principle of equilibrium upon which the bridge has been designed is a very simple one. Under the action of a symmetrical weight the two sections of the river span are subjected to a horizontal stress, which if the weight were permanent would be very small, somewhere about 500 tons at the centre, the weight of the shore spans compensating in great part the weight of the river span. Thus, despite the lowness of the central arch, it has



ERECTING THE MIRABEAU BRIDGE—RIVETTING STAGE been possible to give to the piers the moderate transverse dimension of 10 m. Under the influence of loads on the river span the stress increases, and it can attain to as much as four times the stress produced by the permanent weight alone. The temperature also has the effect of causing a fluctuation in the pushing strains, and this brings into play the jointed anchorage. If the bridge were not anchored in this way, an elevation of temperature would result in the key rising vertically, while the end of the shore span would fall and pull away from the axis of the bridge, and each frame would turn slightly round the articulation of the pier. A fall in the temperature would, of course, result in an exactly opposite movement. As the vertical movement of the shore end would have the effect of breaking up the roadway, the anchoring rods compel the bridge to rise without causing any horizontal movement of the shore ends. The anchorage thus produces the effect of a vertical force, sometimes working in one sense and sometimes in another, according to whether the temperature is above or below that for which the length of the rods has been calculated. When the temperature rises above that for which provision has been made, the reaction of the anchorage causes an upward force and the thrust increases; but when, on the other hand, it falls, the traction is a downward one and the thrusting strain diminishes. The pressure on the foundation under the permanent charge alone is 5 kilos. per centimetre at the weakest point. Under the most unfavourable conditions, when the river span is loaded and the temperature is at a maximum of 40 deg. C., the pressure increases to 14·5 kilos. The different parts of the metallic frames have been calculated so that under the most unfavourable conditions of load and temperature the stress on the steel at its weakest part will not exceed 10 kilos. per square millimetre. The calculations were at first made on the supposition that the frames at the ends of the shore spans would be free. These calculations offer no difficulty in the case of symmetrical loads, because the mutual reaction merely causes a horizontal force. To secure an exact idea of the effect of the anchorage, a calculation was at first made of the influence of a weight of ten metric tons placed at the end of the shore span, and, by comparing the displacement of the end of the shore span caused by this weight with that resulting from the different loads that had been calculated for, it was easy to estimate in each case the reaction of the anchorage on the girders and the effect produced by this reaction. It was then only necessary to add this effect to the results obtained upon the hypothesis of the end girders being free. The influence of the temperature was ascertained by the same means, first by supposing the end girders free, and then calculating the reaction of the anchorage. The same scheme of calculation can be employed to ascertain the effects of dissymmetric charges. An estimate is first made of the raising and lowering of the shore ends and of the key of each half girder, upon the assumption that they are isolated, under the action of the presumed forces, and then the calculation is corrected by taking account of the holding together of the frames. In these calculations no account is taken of the rigidity of the plates, which, of course, adds greatly to the strength of the bridge, though the proportion is not easy to ascertain.

The construction of the Mirabeau bridge was sanctioned in 1893, and was begun in the same year. The metallic caissons were put together on the quay at Javel, and then floated out on the river and sunk. Each caisson had two air locks, one for the labourers and one for the raising of the extracted soil. The first of these was upon the Montagnier system, and the others upon the Zchokke and Terrier systems. The caissons were lighted with electricity. The extracted soil was sent to the surface by a compressed air motor. When the caissons reached the solid chalk, the work of sinking was stopped, and the working chamber was carefully filled with concrete. The sinking of the caissons and masonry was carried on so that their level varied little with the level of the water. The upper masonry was built up all round, to serve as cofferdams to permit of the piers being completed. The first caisson was dropped on August 8th. The work of sinking was commenced a fortnight later, and was completed on October 24th. The first granite block was placed six days afterwards. The sinking of the second caisson took place immediately after the first, and the same machinery was used by carrying the compressed air pipes along cables stretched across the river. The sinking of the second caisson lasted from November 10th to December 30th. The compressed air was supplied by engines placed on the right bank of the river, the installation comprising four engines of a total of 60-horse power, four air compressors, of which two were low-pressure machines, upon the Sautter and Lemonnier systems, for the working chambers, one upon the Roy system for working the compressed air motors, and another upon the Burkhardt system was held in reserve. There was also a small motor and dynamo for the electric lighting. In order to avoid condensation and ice in the pipes crossing the Seine, the air for the caisson on the left bank was heated on the right bank pier, and the air for the motors was mixed with steam. The work of erecting the metal superstructure was begun on September 1st, 1894. The programme of the work necessitated the completion of the first half of the bridge before the winter of 1894-95, so that in the event of high water or of ice interfering with operations, the shore spans could be loaded and the metallic frames rendered independent of the centres. The erection was carried on by means of a travelling crane with a reach of 26 m. Starting with the articulation of the pier, the shore spans and a part of the river span were constructed, and then the river span was completed. The soles of the arcs were first bolted on to the balances, and the collars for tightening them were not put into place until the frames were for the most part completed. The riveting was done partly by hand and partly by a hydraulic machine. A compressed air pump and an accumulator were placed on the Javal quay. The erection of the first half of the bridge lasted from September 1st, 1894, to January, 1895. The removal and reconstruction of the centres lasted from February 26th to April 23rd, 1895, and the erection of the second half of the bridge, begun April 13th, was completed on August 24th, 1895. When the two halves had been constructed, the bridge was regulated, which operation consisted in bringing the two extremities of the bridge in line and in placing them at the required level and in measuring the thickness of the wedges on each arc between the articulation and the frames. Once the wedges were prepared, the ends of the bridge were raised with screw jacks. The wedges were then put in position, and the screw jacks removed, the ends of the bridge thus falling in contact at the proper level. Having thus got the bridge into position, the other work of laying the plates, and paving, &c., was rapidly proceeded with, and the bridge was opened to pedestrians on December 5th, 1895. The work of construction thus lasted for about eighteen months, though it was only lately opened to vehicular traffic. It had previously been submitted to very exhaustive trials lasting a week, when heavy loads were drawn over the bridge under every possible condition, and the way in which it stood the test gave entire satisfaction. The bridge will not be formally opened until the bronze ornaments have been placed in position. The quantity of metal used in the superstructure of the bridge was 2744 metric tons, of which 2077 tons were rolled steel, 385 tons rolled iron, and 82 tons forged steel, the rest consisting of metal for the ornamentation of the bridge. The cost in round figures was 2,067,000 francs, of which the metallic superstructure was responsible for 1,235,000 francs. The work was carried out under the direction of M. Rabel, chief engineer of the Ponts et Chaussées, assisted by M. Résal, the author of the plans, and M. Alby, ordinary engineer of the Ponts et Chaussées. The metallic work was supplied by MM. Daydé et Pillé, of Creil.

THE BOILERS OF TORPEDO BOAT DESTROYERS.

SOME erroneous statements with reference to one of the new "destroyers"—the Sturgeon—having been made in the columns of a daily contemporary generally well-informed in naval matters, we think it desirable, in the interests of the Admiralty, the engineers, and the public generally to explain the reasons why this vessel, and some of the earlier vessels of the destroyer type, are being laid up at intervals.

It may not be generally known that at the time the Sturgeon, her sister ships, the Starfish and Skate, and some others of similar type were contracted for, the boilers of the vessels were, in accordance with the Admiralty specifications then issued, fitted with copper tubes. At that date copper, as a material for boiler tube heating surface, was considered by many engineers superior to steel. The fallacy of this supposition has, however, from exhaustive experiments, been proved, and it is now known that the transmission of heat through clean steel plate is as rapid as through plates of copper.

A few isolated cases of copper tubes having failed in the boilers of destroyers, at the time of their trials, caused the Admiralty officials to decide on replacing, as opportunity offered, all the copper tubes of such boilers by tubes of steel. The fact that coal containing sulphur has in active service been occasionally used to the detriment of copper, has been one of the incentives to the discarding of that material for tubes, and it has been now resolved by the Admiralty authorities that only steel tubes shall in future be fitted in all new destroyers' boilers, and that the existing copper tubes in such vessels shall be replaced by steel. As this resolution was only arrived at some time after the first orders for this class of vessels were given out, the change from copper to steel tubes in their boilers had to be postponed until the vessels were delivered. Before they were, however, handed over to the authorities a few rows of their boiler tubes most severely stressed—or those next the fires—were removed, and steel substituted by their makers, so as to enable them to pass through their official trials and continue running until time and opportunity were found to take in hand and complete the alteration at one or other of the Royal Dockyards.

It is satisfactory, therefore, to know that a commencement has already been made to refit the boilers of each of the torpedo boat destroyers originally supplied with copper tubes, with tubes of steel. The boilers of the Hornet have been so fitted, and those of the Sturgeon are now being taken in hand by Portsmouth Dockyard. The boilers of her sister ships built by the same company will in due time be dealt with, as well as those of the Rocket, Shark, and Surly.

That the Sturgeon is the reverse of "a failure," as stated by our badly-informed contemporary, is evidenced by the fact that she has been in commission since her advent until such time as the previously intended alteration in her boiler tubes could be effected. So far as the vessel and her propelling machinery, &c., are concerned, she has proved herself to be a success, the design and working of her engines and boilers being pronounced as most satisfactory by those best able to judge, viz., the officers who have been in charge of her. The Starfish, a sister ship to the Sturgeon, built and engined by the same firm, has just returned from a five months' commission without a defect list, her machinery, boilers, &c., having been reported as most satisfactory. Should, however, opportunity offer she will in all probability have her boilers retubed before being again commissioned. The facility with which repairs to the type of water-tube boiler—the Blechynden—with which the Sturgeon and her sister ships are fitted, can be effected, is probably the reason why these vessels have been first taken in hand for the substitution of steel in place of their copper water-tubes.

The Blechynden type of boiler has been adopted by Mr. J. S. White, of Cowes, who has fitted it to several vedette boats for foreign Governments, and notably in the 20 knot yacht Scud, illustrated last week, belonging to Mr. Wood, which has been running daily at full speed during the present yachting season, and has proved herself, for her displacement, to be the fastest yacht in the world.

LETTERS TO THE EDITOR.

We do not hold ourselves responsible for the opinions of our correspondents.)

HORSELESS CARRIAGES.

SIR,—With reference to your article in THE ENGINEER of June 5th on the horseless carriage competition, we ask your permission to mention one or two points in which you have scarcely done justice to the motor carriage industry. The majority of workers are naturally unwilling to court commercial failure by offering to the public imperfect and ill-considered machines. But the temptation to be first in the field, and the unusual facilities for obtaining public money at the present time, have proved too strong, and certain companies have already been promoted, whilst others are announced, advertising and exhibiting as commercial autocars machines which are totally unsuitable for general use.

The statement that the Crystal Palace and Imperial Institute contain "the very best horseless carriages in the world,"* does a serious injustice to the general body of workers, some of whom have overcome many, if not all, the objections to which you draw attention, but have prudently refrained from advertising a perfect machine before they have one.

It will point these remarks if we indicate very briefly what we ourselves—the Electric Motive Power Company—have done, leaving to others the task of vindicating themselves. As the result of three years' experimental work in electric, and more recently in oil motors, we have obtained results which we briefly tabulate:—(1) An oil motor using "white rose" American lamp oil, and producing less smell than the benzoline and gasoline motors at present being exhibited. (2) Absence of vibration when the carriage is at rest, the oil motor itself being arranged to stop and start again. (3) Absence of vibration while running, the motor mechanism—whether electric or oil—being entirely separated from the body of the carriage. (4) Connection of the mechanism to the driving wheel by means of a flexible coupling allowing play to the mechanism, and avoiding the noise and wear inseparable from a chain gearing. (5) Simplification of steering and regulating gear, so as to prevent the possibility of mistake or confusion in use.

Many of these improvements not being yet fully protected, it is of course impossible for us to publish details of them; but, in view of the great weight which your criticisms carry, we have thought ourselves justified in pointing out that, even within our own knowledge, the exhibitions which you mention do not fairly represent "the very best horseless carriages in the world." Had the contest been held at the original time, we were prepared to enter our carriages; but we welcome the postponement as affording time for improvements in the designs of autocars, a point to which at present too little attention has been given.

E. T. CLUBBE,
A. W. SOUTHEY.

16, Elm-street, Gray's Inn-road, W.C.

[* The statement to which our correspondents take exception means, and we think obviously means, the best carriages that have so far been made public.—ED. E.]

THE ADMIRALTY PROGRAMME.

SIR,—The Admiralty will soon be working out the programme for 1897, if they have not already started, and before it is too late I should like to put in a plea for another Vulcan. This ship has proved herself simply invaluable in the Mediterranean Squadron, where she acts as a sort of floating dockyard, and executes repairs of all sorts for the whole fleet, besides acting in her most important capacity as a torpedo depôt. Putting the Hecla on one side as totally out of date, the Vulcan is the only torpedo depôt ship we possess, and if anything were to happen to her, either in action, or in peace time through accident, her loss when we have nothing else to replace her would be nothing short of a national calamity. At a time like the present, when we are adding such numbers of those delicate and fragile craft, called torpedo destroyers, to our fleet, a second depôt ship to look after them and keep them in order is surely most necessary, and if we had one now to commission for the Channel Squadron, I have no doubt she would soon prove herself a most valuable addition.

I do not know whether we are to have any more first-class cruisers in next year's programme, but if we are, I would draw attention to a very weak spot in our present ships of this class, which seems to have attracted very little notice. The system of mounting 6in. quick-firing guns in casemates is most admirable, but what enemy is going to waste his time pounding away at 6in. Harveyised armour when a single shell placed under the casemate would blow the whole thing up? In our latest designs the casemate merely sits on the main deck, supported by a few web frames which run down to the protective deck, and which themselves have no protection of any sort. In our Terrible and Andromeda classes, if a shell were to burst under the forward or after casemate, it would in all probability disable two guns—the main deck and the upper deck, as they are directly over each other. There is a similar want of protection to the conning tower supports, and in the Terrible to the 9·2in. gun barbettes; even in our modern first-class battleships, though the casemate supports are protected by the belt, the conning tower, which is considered of so much importance that it is built of 14in. armour, is totally without protection underneath.

RETROP.

Helensburgh, June 15th.

LIGHT RAILWAYS.

SIR,—Referring to the letters of Mr. J. C. Mackay and Mr. J. M. Barker in your impression of the 12th inst., on the above subject, will your kindly allow me to give my experience? I think the best definition I have seen of light railways is that given by Sir Douglas Fox—printed in the "Minutes of Proceedings" of the Institution of Civil Engineers, vol. xxvi., page 49, and which I now quote:—"These—light railways—are either branches from existing main lines, or intended for districts requiring the development of their traffic, and should be constructed in a thoroughly substantial and durable manner, equal in their details as to quality to the best main lines, but with every part made only of such strength as to carry loads represented by the rule that no pair of wheels should be allowed to have more than six tons upon it—this would enable these lines to carry the rolling stock of all other railways of a similar gauge, with the exception only of the locomotive."

About twenty-five years ago I made a light railway in Buckinghamshire about eight miles in length—gauge 4ft. 8½in.; the line followed the surface of the land where practicable, the highest embankment and deepest cutting nowhere exceeding 11ft. or 12ft. There are no road bridges, but three public roads are crossed on the level; there are two brook bridges, or large culverts, each 10ft. span, the curves are easy, with one short one of 12 chains radius. The gradients are good, with one short length of 1 in 50. This line has junctions with the Great Western and London and North-Western railways, and consequently can use the rolling stock of these lines, excepting the locomotives. The maximum speed is limited to twenty-five miles an hour, but, as a rule, the speed seldom exceeds twenty miles per hour. The rails, 32 lb. per yard, are flat-bottomed bridge rails—steel topped—and laid on longitudinal sleepers, with cross ties at every 10ft. or 12ft. The entire cost of this line, exclusive of land, was £1400 per mile.

31, St. Julian's Farm-road,
West Norwood, S.E., June 15th.

WILLIAM LAWFORD,
M. Inst. C.E.

RHEA FIBRE.

SIR,—My attention has been drawn to a statement in your impression of the 12th inst., under the above heading, stating that "since 1883 several methods of treatment of 'Rhea' had been proposed, but none appear to have been applied commercially in this country." This is not correct, as this company has been engaged exclusively, for the last two years, in treating "Rhea," and in combing it, and spinning it into yarns of various counts, for which there is a large and ever increasing demand. The process we employ is that of Mr. H. H. Boyle, which we find both simple and effective. We shall be obliged if you can find space for this statement.

FOR MIDLANDS SPINNING CO., LTD.,
ELIAS NEEL, Manager.

Woodland Mills, Long Eaton, Derby, June 16th.

WALSCHAERT'S VALVE GEAR.

SIR,—It is agreeable and gratifying to see M. Walschaert's beautiful valve gear being accepted, applied, and adopted by a British firm after twenty-nine long years, as witness the engines of the Southend Belle and those of the new cross-Channel boats now running between here and Calais. I well remember in 1867 the drawings of Walschaert's gear being published, and my making a copy of them, and even then it struck me how superior it was to the clumsy, heavy, old link motion which still holds its own in this country, an opinion which has yearly become stronger up to the present date.

M. L.

Dover, June 15th.

PERMANENT WAY.

SIR,—In your interesting article on above important subject, you point out clearly why rails are not fastened to sleepers direct in this country, viz., on account of the softness of the wood used, into which the rails cut their way day by day from the constant concussion of passing trains, and the consequent slackening of fastenings.

It may interest railway engineers to know that by a new process the softest woods can be vulcanised and made as hard as oak, increasing both the strength of the wood, as well as the holding power of spikes, and at the same time preserving it against rot, and the attack of insects in land or water.

The process has had a severe trial of some years in America, and so satisfactory have been the results that the Manhattan Railway Company in America now has, not alone sleepers, but all timber used for whatever purpose, vulcanised.

It is being introduced into this country, a factory is being erected on the Thames, and in the course of a few months engineers will be able to avail themselves of a great boon. The process is much cheaper than, and far superior to creosoting, as it can be worked by tools, and it goes through and through the wood.

M. INST. C.E.

WIRE ROPE MANUFACTURE.

SIR,—In your issue dated 12th June you state in a paragraph that wire manufacturers and wire rope makers have seldom been more fully occupied. I assure you, Sir, you are in error, as I doubt whether either of the above-named industries have ever suffered such depression and want of orders as at the present time.

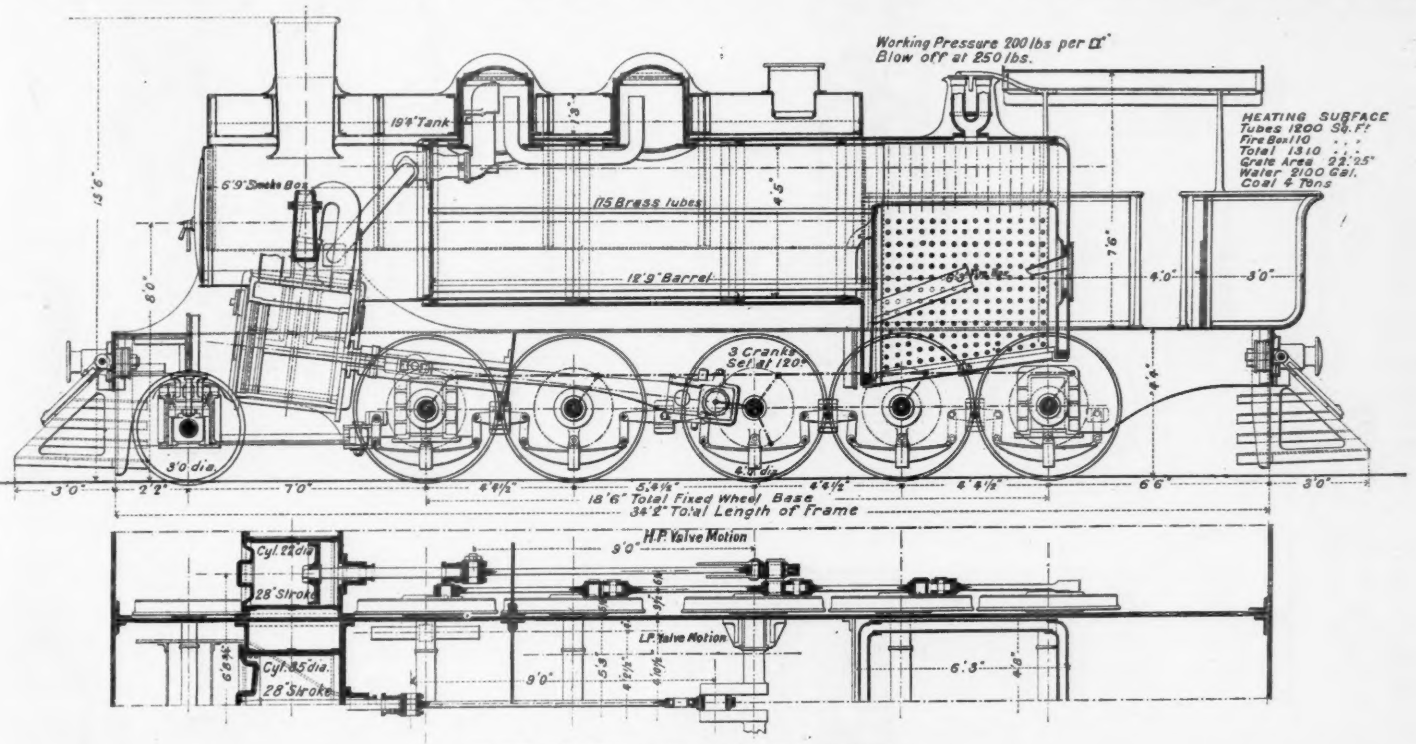
Why, I should have thought that the depressed state of the coal trade, the African trouble, and last, but by no means least, foreign competition—this I do not mean in England, but more particularly so in our continental markets—sufficient to contradict such an assertion. I am only too sorry that trade is not as you state.

June 15th. ROPE MAKER.

TRIPLE-CYLINDER LOCOMOTIVES.

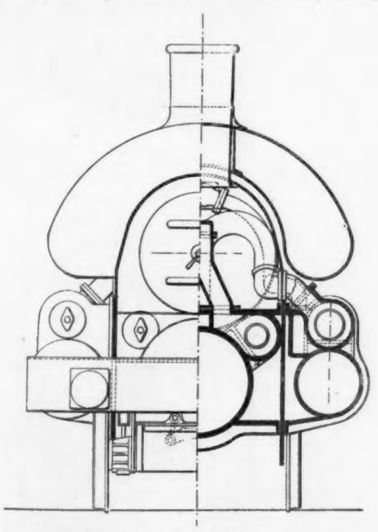
SIR,—Your article on the above which appeared in your issue of 13th March is, in my opinion, a step in the right direction towards making the compound locomotive a successful engine, but only in so far as the number of cylinders mentioned.

There appears to me to be no precedent to justify any one building a compound engine with three cylinders of one diameter as you suggest. Marine engines have been made with one high and two low-pressure cylinders; the latter, however, were not of the same diameter as the former.



RIEKIE'S COMPOUND ENGINE FOR STEEP INCLINES

To my mind the principal object in compounding is, or should be, to use up the steam to the lowest limit of pressure, in fact to get as much work out of it as possible before exhausting. Al condensing engines do this with success, and it appears to me, that to meet with any chance of success when compounding a locomotive engine, we must follow on the same lines; it may not yet be practicable to make a condensing locomotive, so as to work the steam down below atmospheric pressure; it is, however, practicable to work a non-condensing low-pressure cylinder with a steam pressure of 15 lb. to 20 lb., so that the outside low-pressure cylinders of the locomotive engine you suggest would require to be very much larger than 23in. to enable them to be worked with such a low pressure of steam to get economy, and at the same time exert nearly the same power as the high-pressure cylinder. I cannot conceive how three cylinders of one diameter can be successful as a compound; in the first place the exhausts would have to be at high pressure to get good work out of the low-pressure cylinders; moreover, the four exhausts would not be harmonious to the ear. The most difficult problem of all is getting equal work out of each cylinder, and this latter I look upon as a most important factor in a three-cylinder engine. It is true compound locomotives can be made to exhaust at 30 lb. to 40 lb. pressure and so effect a saving over the simple engine exhausting at a higher pressure; this saving, in my opinion, is not good enough. It is necessary to effect a more substantial saving, and I consider that two exhausts as low as 5 lb. to 10 lb. must be reached to make a compound locomotive the success it should be. There is no doubt that this can be accomplished.



CROSS SECTION

Like a few of your correspondents I also have made a careful study of compound locomotives. Many years ago I came to the conclusion that the two-cylinder locomotive was a most unmechanical machine, and I considered it advisable to effect an improvement in the principle of the same.

I took out a patent a few years back for an "Improved Locomotive" to turn the wheel on a constant fulcrum. I may here mention that I also sent an article to your paper in 1892, expecting to be able to start a discussion, and thereby prove to the mechanical world that the power used in turning a locomotive wheel was misapplied. Unfortunately I brought up the question of the fulcrum of the lever of a locomotive wheel—which I maintain is alternately at centre of axle and crank, pin during each revolution—this was sufficient to raise a hornet's nest, so I let the matter drop. I would here like to touch upon that discussion.

"Text-books" and able exponents explain that when the crank is below the axle the pressure on the crank pin tends to push the lever backward, &c. No wonder students are ever raising the question as to how the wheel is caused to rotate when such a fallacy is propounded. In my opinion no amount of thrust can have any such tendency.

Again, if a locomotive wheel is turned similarly to a stationary engine wheel, why is it that both practical and theoretical men are so divided in opinion as to the fulcrum of the lever? Not a few refuse to go into the question of leverage, and argue that the wheel is turned by alternate pressures on the axle-box and cylinder cover.

Now, to my mind it is this alternate pressure or alternate work done in turning the wheel that prevents it from being an efficient machine, and has thus far prevented it from being successfully compounded.

I will now make the bold assertion that a grave error was committed in applying two cranks to a locomotive engine. The minimum number that should have been applied is three, and these should be at angles of 120 deg. to one another, so that the work done in turning the wheel would be constant; in other words, the wheel would be made to rotate by a constant pull or push at a constant point of the wheel. Let any practical man consider the result of turning the wheel of a locomotive with both crank pins alternately above and below the axle; in the former case the pistons are pulling the wheel forward by the crank pins whilst the cylinder holds the axle, and in the latter case the pistons hold the wheel by the crank pins whilst it is pulled forward by the cylinder, and when it is considered that no amount of push on the crank pin can cause the wheel to rotate forward, he may agree with me that the two-cylinder locomotive is the most unmechanical machine of the nineteenth century; certainly, to my mind, a more unmechanical device cannot be conceived. Moreover, the result of having the cranks alternately above and below the axle as explained, necessitates balancing the same not by any accepted rule, but as each locomotive engineer may fancy. Again, when an engine is starting a train, the adhesion is greatest when the crank is below the axle, and it gets gradually less and less—when in this position—as the speed increases.

Engineers have for many years made a study of balancing the wheel to get the engine to run steadily. Their chance of success in this direction, in my opinion, is very remote if they still adhere to two cranks.

Railroad engineers have good ground for complaining about their roads being damaged when such conditions exist.

You mention that a 32in. low-pressure cylinder is the largest that can conveniently be put in an engine in England, and that 1245 square inches of piston area can be had from three 23in. cylinders, as against 1015 with one of Mr. Webb's present engines. Now, it may be; and I have no doubt that it is, impracticable to get larger outside cylinders on to a Webb engine, and so comply with the demands of modern practice. I, however, have patented a compound system, which enables me to get two 20½in. outside cylinders on an engine having a 32in. low-pressure cylinder. Such an engine would have 1464 square inches of piston area, and would consequently be considerably more powerful than the three 23in. cylinder engine. Moreover, I have the designs of a Ghat engine for a 5ft. 6in. gauge railway, which can have two 24in. outside high-pressure and one 38in. inside low-pressure cylinders, and which would have over 2000 square inches of piston area.

Accordingly, in plain words, I advocate a new departure from modern practice, and propose working expansively in two high-pressure cylinders, exhausting from both into the receiver during one stroke of the low pressure piston, delivering the steam at different parts of the stroke to the latter; keeping up a constant pressure, and getting over "receiver drop," instead of cutting off late in one high-pressure cylinder, and exhausting the steam at one gulp, and having a heavy drop. This may be opposed to the acknowledged practice of keeping up the temperature in the walls of the cylinder when cutting off late in the high-pressure cylinder; however, such an engine is at work in India, and gives satisfactory results. These results may be due to the fact that a wider range of expansion is obtained by this system, power for power, than that of any other, and which more than compensates for any loss due to condensation. I may mention that the maximum cut off in the high-pressure cylinders of this system is 50 per cent.

You imply that the compound system can only work to advantage with a load of 200 tons, fast speed, and long runs. I maintain that a compound engine, to be a success, must be able to do every kind of work that a simple engine can now do, and do that, too, more economically by 30 per cent. to 40 per cent. in fuel consumption. It may be said that a third cylinder enhances the wear, by adding more wearing parts to the machine. This, however, is not the case, the three cranks have the work now done by the two distributed between them; moreover, taking the knock off the axle-boxes does away with "pounding"—this improvement is applicable to any two-crank engine, stationary, or otherwise—an engine so constructed will run for months without requiring any repairs whatsoever, a very much different state of affairs when compared against the existing two-cylinder compound engine.

Not a few locomotive men will naturally be chagrined at the fact of a locomotive, with 5ft. 6in. wheels, having attained a higher speed than an engine with wheels of larger diameter. No doubt greater power can be developed with the small wheeled engine. If, however, an engine having wheels 9ft. diameter were built with a piston area such as I recommend, the result would be a higher rate of speed than anything yet attained. I will go a step further, and say that one type of engine, with 7ft. wheels, should be powerful enough for all kinds of work from slow heavy goods to fast mail trains.

The question may be asked, what about a boiler for such an engine? Well, a slightly larger one might be required for the 24in. and 38in. cylinder engine, but for the 20½in. and 32in. cylinders a boiler no larger than the ones now in use on the Great Western Railway would be necessary; indeed, the same volume of steam would be used, but over larger areas. A very important improvement in my proposed system is, that the power of an engine would be so increased that either two 17in. or 18in. outside cylinder, with inside ones to suit, would be able to do more work than is now done by a 20in. cylinder engine, the result would be a substantial saving in fuel consumption and wear and tear to machinery. The enormous wear that now takes place with two-crank engines, when put to heavy work, requires to be seen to be realised. A fair example can be had from engines working on 1 in 25 grades; it is true, on the level this may not be so apparent. All the same, from my practical experience, I should say that the Great Western Railway engines are very heavy in repairs, and I have no hesitation in saying that had three 16in. cylinders been used instead of two 20in., a better engine would have been the result, and it would have paved the way for successfully compounding the locomotive engine.

I should recommend small-wheeled engines to be kept for grade climbing. An engine with 4ft. wheels, having a piston area of 2000 square inches, would be the most powerful engine yet made, and as the exhaust could be reduced to a pressure of 10 lb., or even less, the engine would not only be economical in fuel consumption, but also in wear and tear to machinery and boiler.

I send you the prints of a "Mail and Ghat" engine, and which you may be pleased to publish with this.

JOHN RIEKIE,
Dist. Loco. Sup. N. W. Railway, India.

Sukkur, May 5th.

A COALING station for the German Navy at the eastern mouth of the Emperor William's Canal is to be begun shortly. The coal stores, which will be 570ft. long and 65ft. broad, are to be on the south side, close to the harbour for torpedo boats. They are intended both for coals and briquettes, and will have seven loading stages, and be encompassed by a railway with several lines of rails, three of which will run along the stone pier separating the torpedo-boat harbour from Kiel Bay. The water by the pier is so deep that a fleet of warships could coal there. The station is to be finished in two years, and will be able to store about 77,000 tons. A coaling station of similar size is to be formed at Brunsbüttel, at the western mouth of the canal.

Yearly	*£1 16s. 0d.*
THICK PAPER COPIES—	
Half-yearly	*£1 0s. 3d.*
Yearly	*£2 0s. 6d.*

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF JUNIOR ENGINEERS.—Thursday, June 25th, 6 p.m. to 8 p.m.: Visit the Engineering Works of Messrs. Bryan Donkin and Co., Bermondsey.

THE ENGINEER.

JUNE 19, 1896.

THE NEW COAL CHARTER.

THE new charter party issued by the Chamber of Shipping, which has not been accepted with any particular friendliness by London charterers, appears to be creating a crisis in South Wales. Crises in that part of the kingdom have hitherto been associated with wages disputes and strikes of colliers; but the disturbance with which the Welsh coal and shipping trade is now menaced takes the unexpected form of a strike of one strong body of capitalists against another equally powerful capitalist combination. In its present aspect, indeed, it is a struggle between the shipowners of the country and the colliery proprietors and charterers of South Wales. The origin of the strife must be sought as far back as January, 1895; but so obscure was the issue, and so complicated the questions involved, that for more than twelve months no one heard a whisper of impending trouble, and it was actually not until a fortnight ago that the commotion began which threatens serious and, we might say, disastrous consequences. At the beginning of last year the Documentary Committee of the Chamber of Shipping framed a new form of charter party, which was admittedly directed against the coal shippers of the Bristol Channel ports. The reason given for this action was that for years—in fact from the commencement of the growth of Cardiff into a great coal port—the shipowner had been at the mercy of the charterer; and what with competition at home and from foreign vessels, he was forced to accept terms which lessened his profits and crippled his enterprise. One of the terms complained of in the old charter was that the wharfage toll of 2d. per ton was levied on the ship, whereas the shipowner contends that it ought to be paid by the shipper of the cargo. It is not in dispute that the wharfage has been paid by the vessel ever since Cardiff Docks were opened; but the shipowners say that they accepted the burden because it did not amount to much in the early days of the oversea coal trade, that they have since submitted to it because of their helplessness, and that they are revolting against it now because they are in a stronger position to fight, besides which they are supported by a wealthy phalanx of Protection and Indemnity Associations.

The argument of the charterers, including coalowners representing an output of twenty-five million tons per annum, embraces a variety of technical points, but it is chiefly based on principle. The wharfage dues, they say, are justly levied on the ship, and have nothing to do with the cargo. They point to the fact that hitherto the shipowner has always been content to pay the 2d. per ton, and has reckoned it in his estimates of freight. They insist that it would be impossible for them to transfer the wharfage dues to the price of coal, especially in these days of keen competition, without risking the loss of customers, and diverting trade from the Bristol Channel. It is idle to point out, they urge, that the consumer pays the 2d. per ton in the ultimate result. However that may be, the South Wales colliery proprietor points out that he ships his coal f.o.b., and could not recoup himself in the price as the shipowner can in the freight. But there is another and perhaps a stronger objection raised to the Chamber of Shipping Charter. The document is to come into force on July 1st, except where charterers gave notice by Monday last that they were willing to be bound by it, and in those cases its enforcement would be postponed until January 1st next. Now, a great part of the oversea trade of the Welsh ports is conducted by contracts of a more or less lengthy run. The contract is made at a specific rate f.o.b., and makes no provision for the 2d. per ton the shipowner wishes to saddle upon the shipper. Here it would seem that the resolution of the shipowners would inevitably involve the contracting coalowner in an immediate and continuing loss. The long and the short of it is that the South Wales colliery proprietors have made common cause with the general body of charterers; and at a meeting representing 25,000,000 tons per annum, it was determined to offer the stoutest resistance to the new charter, the coalowners present entering into bonds not to ship, or permit the shipment of, their coal on any vessel sailing under the new rules.

These circumstances point to a complete deadlock, and the colliery proprietors are making every arrangement to face it. As Mr. J. B. Ferrier, late president of the Cardiff Chamber of Commerce, remarks, it would mean a total suspension of trade such as the Bristol Channel ports have not known since the great strike of 1875. It appears incredible that such a condition of things should be allowed to arise out of a petty twopenny toll; but Mr. Ferrier discovers no way of escape except in an abatement of the shipowners' demands. "I do not see," he says, "how negotiations are possible. So far as the coalowners are concerned, they are simply on the defensive. The shipowners have made war with the colliery proprietors; we shall resist them, and they will find that they have tackled a stronger body of men than they anticipated." Yet, despite these ominous words, it is impossible to resist an impression that the outlook for the 1st of July is not altogether so gloomy as the reports from South Wales represent. Of course, there are many vessels chartered in advance under the old conditions, though the stringent rules of the indemnity societies render it doubtful whether those charters will be renewed after the voyages are over. But it must strike an impartial mind, that in assuming an attitude of "no compromise" the Chamber of Shipping has left out of account the vast amount of foreign tonnage which is ready for employment wherever opportunity offers. Something has been said, it is true, of foreign co-operation in opposition to what are known as "dirty" charters. The wharfage due of 2d. per ton, however, does not touch the questions involved as between "clean" and "dirty" charters. To the foreign shipowner it must rather appear a domestic squabble between shipowner and charterer, and one in which he has no interest so long as his stipulated freight is paid. If the colliery proprietors resolve upon an absolute stoppage, and to close their pits in order to bring the British owner to terms, the responsibility will rest upon them. The only excuse for such a step would be dire necessity, and the necessity could not arise while a supply of shipping, of whatever nationality, was seeking orders at the Welsh ports.

Although a number of Cardiff coal exporters provisionally accepted the charter on Monday last, and so gained six months' grace—the wharfage being meanwhile paid by the ship as heretofore—the colliery proprietors regard the position as unaltered. The Monmouthshire and South Wales Coalowners' Association met on Tuesday, and re-affirmed the decision of the joint meeting of the coal trade in the previous week, while anew expressing a unanimous opinion in favour of determined resistance to the shipowners' demands.

THE MANAGERS OF OUR ORDNANCE FACTORIES.

IN days when the skilled mechanic earns higher wages than formerly, it is strange to find the special skill and experience required for the successful direction of mechanical operations on a large scale made little of. This, however, is, we think, unquestionably the case in the Royal Arsenal and the kindred Government manufacturing establishments. We are not now speaking of our dockyards, but of our factories at Woolwich, Enfield, and Waltham Abbey. Strange as this is, it is still more curious that on this state of things being represented by numbers of witnesses to a Committee which was appointed to inquire into the organisation and administration of the manufacturing departments of our army under Lord Morley, and on this Committee strongly recommending that the evil should be remedied, steps were taken to aggravate it in a peculiar manner, so that our managers now stand on such a footing that it might be supposed that some malevolent influence had been exerted to injure the department. That the country has suffered, and must suffer, from so baneful a state of things goes without saying. To put the matter forcibly, let us see what would be as sure and efficacious a way as we could well devise to put managers in a bad position, and then we shall show how nearly this has been approached in actual fact.

To put managers in a false position, and to subject them to special temptation, it would be desirable that they should be without private means, very much underpaid, studiously annoyed, and made little of. This, if combined with great responsibility and influence, with opportunities of obtaining by wrong means what was not given to them for their services, both in the shape of actual money and in advancing the interests of their relations and friends, ought in the long run to produce the result aimed at. It ought to develope a system on which contractors and managers square matters a good deal between them; a system by which on paper the country appears to obtain services cheaply, but for which the country really pays dearly, without being able easily to trace where or how much.

This suggests an ugly picture, and we do not like raising it in connection with a body of men whom we believe at the present time to be doing excellent work, and against whom we have not a shadow of a charge. Indeed, we fear that they are likely to be annoyed at our taking such a line of argument. We may say at once, then, that we are only pointing out what ought to happen, and what must sooner or later occur in individual instances when a system is pursued calculated to foster it. Many years ago all this was urged, and it was urged in the abstract, deprecating any shadow of allusion to any individual. Since that, certain individual managers have been discharged under circumstances bearing out what had been urged. Our object now is simply to get justice done to good men on whom we greatly depend. It is necessary to show that we do depend on them, and this could not be if it were impossible for harm to come, however badly we treat them. We do this especially because it is the only way we know in which to defeat an obvious rejoinder. For suppose we urge that our managers are badly paid and are badly treated, we are at once met by the rejoinder, "Why then do they not go to private firms? It is quite clear that Government service has attraction and advantages which compensate for the great difference in pay, or else they would not remain." Now, this is a most dangerous plea to urge unless we know the exact nature of the attractions and advantages. To assume that they must exist without being able to define them, is to run the greatest risk of their being of a mischievous kind. Let us see whether there are any that we can put our finger on now, which will account for the presence of the valuable men we have at the present time. Formerly managers were what is called "on the establishment," that is to say, they were entered like other members of the permanent staff. They received yearly salaries, and eventually became entitled to pensions. This, with the certainty of the permanence of a Government establishment, might no doubt carry considerable weight. Immunity from the annoyances connected with trade disputes counted for something, so that altogether their pay, and that of managers in private firms, might be expected to stand somewhat in the relation of interest on a Government and private investment. This advantage was strained to the utmost, and, indeed, overshot, before the sitting of Lord Morley's Committee, as is apparent from the evidence given on all hands. Sir Andrew Noble, for example, said that an accountant received £650 in a private firm, and that managers ought to be paid much more highly. Mr. Engelbach, of the War-office, said that the managers were very talented men, and ought to have their present position raised, and that their salaries were not at all commensurate with their responsibilities. Sir H. Alderson said that they were able men and underpaid, and recommended that their pay and position should be improved. Colonel Barlow, Colonel Arbuthnot, and General Close, all spoke strongly in the same sense, and we can find nothing opposed to it, unless it be that General Maitland urged that while their pay should be increased, they should be taken off the establishment. It is not surprising, then, that the Committee should have recommended that in addition to the advantages of security of position, "the State must be prepared to approach nearer than at present to the salaries obtainable in civil life," and get the best men as managers. It will scarcely be credited that since that Committee sat, while no increase of pay has taken place, the managers have been removed from the establishment, their hope of pension has been taken away, and they have been paid by the week, like the mechanics and labourers of the department, and are liable to be discharged at a week's notice.

It is very apparent that the weekly pay of about £8 13s. 1d. on the precarious tenure of a possible week's notice is not enough to induce a good man to undertake the position of manager over an establishment turning out, perhaps, three, four, or five hundred thousand pounds' worth of work in the year. It is more difficult to say why we should still have the good managers we believe that we possess. We account for this mainly because they have a strong hope that the present anomalous state of things must come to an end, and having been long in Government service, they hesitate to throw up all hope of better times. We trust that the event will prove them to be right; if not, we fear that things must get worse in some way. Good managers may leave, and we may get bad ones. Observe: we are advocating paying highly in order to buy efficiency, not honesty. Nevertheless, we do hold that it is both wrong and foolish to put men in an unfair position, to treat them very badly, and to assume that they know how to take care of themselves, though we see no visible legitimate way in which they can do so. Our clerks are all established and pensioned; the managers of our dockyards are established and pensioned. How can it be right and wise that this should be the case, if it is right and wise to refuse our War Department managers the same privileges? However important is the administrative work performed in our offices, the end and aim of a factory is to manufacture war stores, as completely as it is the aim and end of a gun to shoot. In each case everything fails if this one end is not attained. We believe that it would pay the country well in the long run, not only to be reasonably fair, but even liberal. Again, we have long held also that to withhold any benefit which costs the country nothing, is to defraud both the country and the individual concerned. We have never heard of a private firm where managers are paid weekly. The tendency of such a system is to degrade them. Who benefits by this? Is it not obvious that either country or manager is injured, and probably the injury is divided between them. The individual manager feels it first. Eventually the less pleasant position ought to end in less good servants being secured. So with other anomalies; at present the superintendent of a department is the only officer to direct the manager under ordinary circumstances. Should he be absent for a day, it might be supposed that the manager who has worked with him all along, and knows his views, is the natural man to carry them out; but that is not the official view. Will it be believed, that either an officer from a central office in the Arsenal, or the chief clerk of the department, is for this very short interval placed over him?

Our own idea of a manager would be to select the best man we can get, and to put him in a thoroughly good position as to pay and status. With the one exception quoted above, we have never heard of an officer who wished to purchase the power of dismissing a manager at a week's notice by disgusting the entire body of them. We should increase the pay largely, and above all place the managers on the establishment. Experience shows that for one superintendent who prizes the luxury, as it were, of instantly killing and taking possession when he thinks he has a bad man, many would value the hold of a secure future for a good man. We should encourage in managers, as we should in officers, the desire for distinction by putting forward any designs or good suggestions in their own names. The extinction of all this has for many years past been a fixed principle, though for what conceivable reason, except jealousy, or a wish to take credit due to others, it is hard to conceive. Of all rewards, reputation is the one that it best pays to use; for while it costs the country nothing, in the nature of things, it comes only to men who have produced good results. Next, in the selection of men, we have not much fault to find, but we believe this, like everything else, would become easier with higher prizes to offer. Capital men have been taken from Admiralty yards. They might also be taken from private firms. We think also that it ought to be possible for a specially exceptional man to rise from the bench. In the latter case, however, everything should be done to make it clear that the man had entered an entirely new position as completely as a soldier rising from the ranks to be an officer. It might in such a case be easier for such a man to move to a new place and begin in a new sphere altogether. Doubtless the result of this would be to show larger items in salaries, but those who know most of our manufacturing departments are aware of what a small element this is compared with the money that is absorbed in various ways, only traceable by those who "know the ropes" under our present cumbrous arrangements.

LORD KELVIN.

During the week Lord Kelvin's jubilee has been celebrated in Glasgow. It is not given to many to fill a professor's chair for half a century. Lord Kelvin has received the well-merited congratulations of the whole scientific world and of Royalty itself. The principal events of his life are too well known in the world of science, and have been too recently detailed for the general public to need re-statement here. The work done by Lord Kelvin during a period of more than half a century has been so considerable that it is much to be regretted that the daily newspapers vie with each other in exaggerating its influence and importance. Lord Kelvin is the last man on earth to be pleased by adulation, or charmed by unintelligent glorification. His dignified reply to the speech of the Lord Provost of Glasgow University on Tuesday evening should serve to silence men who have no proper conception of what Lord Kelvin really has achieved. "When I think," he said, "how infinitely little is all that I have done I cannot feel pride; I only see the great kindness of my scientific comrades, and of all my friends, in crediting me for so much. One word characterises the most strenuous of the efforts for the advancement of science that I have made perseveringly during fifty-five years; that word is failure. I know no more of electric and magnetic force, or of the relation between ether, electricity, and ponderable matter, or of chemical affinity, than I knew and tried to teach my students of natural philosophy fifty years ago in my first session as professor." These are pregnant words. It would be well should all who teach bear them in mind. The history of Lord Kelvin's career is well known. He has done nothing great in the sense that Newton or Faraday, Watt, or Stephenson did great things. A fine mathematician, he narrowly missed becoming a poet. His imagination has built up for him fairy realms in the ether, which it may almost be said that he invented. To him the life's history of the sun has formed a vivid picture; and the conception of a world of matter composed of countless myriads of gyroscopes, spinning one within another, originated in a brain which in mediæval days would have found the picture of a million angels dancing on the point of a needle, a thing of delight. No man living has taken keener pleasure in the scientific use of the imagination; while his mathematical dexterity enabled him to bring into order and discipline the atoms whose contemplation gave enchantment to his soul. Leaving theory and turning to actual work, we see that his labours have supplied the world with a splendid collection of electrical and nautical instruments, and little else. It is true that he greatly aided the work of submarine telegraphy; but it is questionable if his mirror galvanometer or syphon recorder can compare in ultimate utility to the world with multiplex telegraphy, concerning the inventor of which not much is heard; and the telephone is not second in importance to any of Lord Kelvin's inventions. He has done excellent service to science, and we heartily unite with Glasgow and Glasgow University in doing him honour. But succeeding generations will be more likely to remember him for what he has done than for what he has taught; and his memory will endure, not because he was great in great things, but because of his mastery of the almost infinitely little. The man who made it possible to send a message through an Atlantic cable, with a battery formed of a lady's thimble and a fragment of copper wire, stands on a different pedestal from the men who taught the world how to cross the Atlantic by taking some of the water out of it and boiling it. Lord Kelvin deserves all that those who best know him will say in his praise. From his "Friends" in the daily press, he may well beg to be saved.

YORKSHIRE MINERS.

Rotherham, once so important that letters to the city which now joins hands were once addressed, "Sheffield, near Rotherham," was on Monday the *venue* of the Yorkshire Miners' Association in their annual demonstration. Forty special trains brought into the ancient borough a multitude of visitors, it being estimated that the aggregate gathering considerably exceeded 60,000, who spent the day in processional display, listening to the music of over sixty brass bands, and the addresses of a score or so of speakers at three different platforms. At each platform two resolutions were passed. These resolutions, as usual, were in effect miniature manifestos from the miners' leaders, covering almost every topic of the mining movement upon which the colliers' executives have set their hearts. Interest chiefly centres in what Mr. Benjamin Pickard, M.P., had to say. As the President of the Miners' Federation of Great Britain and Ireland, and the Secretary of the Yorkshire Miners' Association, Mr. Pickard, more than any other man, is able to forecast the situation in the coalfield. He made two points very clear. The Union had "burnt its boats" over securing a minimum rate of wages. Having succeeded in that effort, they now mean to stick to what they have got. Mr. Pickard scouts all notion that high wages ever killed any trade. Two things he regarded as vital to business—keen competition and the giving of profits away to the middleman. The miners, he contended, were at one in declaring that their wages never caused 1 per cent. alteration in the dividends up or down. He was equally resolute in demanding that so long as the owners gave their profits away, they ought not to call upon the men to make up the deficiencies. "We are not going to stand it," said Mr. Pickard; "we believe the wage we now have is a living wage, if we can work every day in the week, and we will have it continued." Noticing the contention of some owners that a reduction of wages was necessary to enable them to compete effectively with Durham, Northumberland, and Wales, Mr. Pickard replied that the miners did not want to go down to 4s. 2d. a day. Turning to the other point of interest, the Conciliation Board, the speaker said that the coalowners were wanting to meet the miners to try to get a further Board of Conciliation. But the Conciliation Board, so far as the miners' officials understood it at present, was to be "one with a Lord Shand in it." Mr. Pickard, it would thus appear, is not in love with Lord Shand. If the miners' officials can agree with the owners, he is quite content, but he declines to be a party to the other point. As to what was likely to happen at the adjourned meeting between coalowners and the miners' representatives, Mr. Pickard refused to be drawn. Silence sometimes, he said, was golden, and he wanted his hearers to have all the gold. It is quite clear, however, that the policy of "no reduction" is to be maintained during the coming struggle, if there is to be one. The general opinion is that there will not be one, and that the existing situation will be continued, the miners retaining the advantages they enjoy at present, even although their working hours may be reduced, and the amount of money they take home at the week end be considerably less than would be earned under concessions which would enable their employers to obtain a larger share of work, and thus give increased employment. All the speakers at the Rotherham demonstration appear to have got hold of one vital point. They altogether deny that lower wages would help the coalowners. They believe that if coal cost less in labour, the miners would be worse off, and their masters no better. Their doctrine is that the only way to sustain values in the coalfield is to sustain wages, and one of the speakers, who is President of the Yorkshire Association, boldly controverted the idea that a reduction of wages could possibly bring them any more work. He pointed out that new pits were being sunk on every hand, and that there were now 134,000 more men employed in mines than in 1889, and that capital had been enormously increased, and the power of production so abnormally augmented that it was impossible for lower wages to bring about greater employment. The Yorkshire Miners' Association, therefore, which may be regarded as the keystone of the Federation, has decided to stand fast for what their president calls "the great principle of a minimum and fair wage," and Mr. Pickard points out that they are in a position to speak with some authority, having a membership of 50,000, and a nest-egg of about £100,000 with which to back up their demands.

FIRING AT CAPTIVE BALLOONS.

In the "Proceedings" of the Artillery Institution is a translation by Col. J. H. G. Browne of an article, in the *Revue Militare de l'Etranger*, on the attack of captive balloons by artillery. Experiments were made on this in France, Germany, Russia, and Austria in the years 1885-87-91 and 94 respectively. On the 10th July last at the fortress of Steinfield, forty miles from Vienna, some fresh trials were made. The earlier series of experiments had established the fact that the balloon has only one enemy, namely, the cannon, and that small holes produce an inconsiderable effect even in large numbers. The difficulty of laying the gun increases with the altitude of the balloon; sometimes it is found necessary to dig a hole for the trail, which makes the service of the gun slow and difficult. The balloon, therefore, should be as high as is consistent with effectual observation. The Austrians think that an altitude of about 800 metres (2625ft.) has the advantage of spoiling the enemy's fire while allowing observations to be made. About 4000 metres distance (4375 yards) places the balloon outside the effective range of field artillery, without being so far off as to prevent the points which it is desired to examine being distinguishable. Lastly any motion of the balloon, vertical or lateral, renders artillery attack specially difficult. On these premises the trials of July 10th last were commenced. The balloon was placed 5000 metres (5468 yards) from the battery, and at a height of 800 metres (2625ft.) and was twice put in motion during the execution of the fire. The balloon, the Budapest, was 10 metres (32ft. 9·6in.) in horizontal, and 14 metres (45ft. 11in.) vertical diameter, it was raised to a height of 800 metres (295ft.). As soon as it appeared, an eight-gun battery of 8 centimetres (2·6in.) guns began firing at it from 5250 metres (7641 yards) with angles of elevation varying from 25 to 27 degrees, trenches being dug for the gun trails. After eight rounds the range was estimated within about "1000 paces," when the balloon was seen to be moving, and the range had to be found again. This experience was repeated till the eighty shrapnel allotted for the work had been expended, discharging about 10,000 bullets, while the balloon still floated tranquilly. It was eventually found that three small holes had been made, which had no sensible effect. From the above it is thought that a large rent is needed to cause an immediate fall, indeed this had actually been brought about in early trials. A captive balloon at 2625ft. elevation and 5468 yards from an enemy by changing its position occasionally has a great chance of remaining intact. Probably, then, a balloon pack marching 3000 metres (3281 yards) in rear of the artillery of the advanced guard of an army ought to be able to do good service. To this we are tempted to add that in many cases it might be worth while to make an ascent with an empty balloon first to test matters and draw the enemy's fire.

LITERATURE.

Field Artillery. By Lieutenant-Colonel Sisson C. Pratt, late R.A. Revised by Lieutenant-Colonel Eden Baker, R.A. Kegan Paul, Trench, Trübner, and Co., Paternoster House, Charing Cross-road. 1896.

Our reason for noticing the new edition of the book just brought out is that England has recently made important changes in field artillery, and that Colonel Baker, who has in this edition dealt with the question, is a high authority on the subject, and from his position at the Artillery College in Woolwich is at the focus of information. The book is a capital compendium of information on field artillery brought up to date. Our object here is to notice only one branch of the subject, namely, the position in which England stands compared with continental powers in the matter of field guns. This is shown in a series of tables in the chapter on gunnery. We have recently introduced for our Horse Artillery a breech-loading 12-pounder gun weighing only 6 cwt., discharging a shrapnel weighing $12\frac{1}{2}$ lb., containing a $1\frac{1}{2}$ oz. bursting charge and 156 bullets, with a muzzle velocity of 1550ft. per second; and a field battery gun weighing 7 cwt., with a shrapnel of 14 lb., with a velocity of 1550ft., and containing 235 bullets. Germany has a light piece, presumably her Horse Artillery gun, weighing 8·27 cwt., with a shrapnel weighing 17·78 lb., containing 262 bullets, fired with a velocity of 1375 foot-seconds; and a field battery gun weighing 8·66 cwt., for a shrapnel weighing 15·5 lb., containing 300 bullets, with a velocity of 1450 foot-seconds. These are, of course, much heavier pieces. France has a Horse Artillery gun weighing 8·36 cwt., with a shrapnel weighing 13·5 lb., containing 40 segments and 120 bullets; and a field gun weighing 10·43 cwt., with a shrapnel weighing 19·13 lb., containing 77 segments and 160 bullets; while Russia has a Horse Artillery gun weighing 7·19 cwt., with a shrapnel of 15·59 lb., containing 165 bullets, and a velocity of 1352 foot-seconds; and a field gun of 8·64 cwt., firing a shrapnel of 15·59 lb., containing 165 bullets, with a velocity of 1450 foot-seconds.

The practical value and power of field guns depends on the following elements:—Muzzle energy of the projectile, flatness of trajectory, accuracy of shooting, number and weight of bullets and fragments, and spread of them, for field guns now depend wholly on shrapnel fire. Some of these conditions involve difficulties and contradictions. For example, a high velocity gives a flat trajectory, but renders any error in setting a fuse very serious. Still, we may take the above as the elements to be desired. The muzzle energy, and consequent flatness of trajectory, represents the achievement of the gun; while accuracy of fire depends partly on gun and partly on projectile, and the after behaviour of shrapnel depends on the projectile alone. To compare the achievement of the guns as to delivery of energy, we must take their weight into account, and it is usual to follow Krupp's plan of dividing the total energy by the weight of the piece in tons, which gives the energy per ton of gun. This carried out gives us, in foot-tons, per ton of gun, for the Horse Artillery guns, in order of merit: British, 710·6; French, 578·8; German, 563·7, and Russian, 549·4. And for the Field Battery: British, 666·2; French, 566·3; Russian, 526·1, and German, 521·9. In this respect, then, the British guns are very far the best. The question, however, is not completely represented without taking the weight of carriages into account, and this we are not in a position to do, the figures not being yet obtainable. Supposing the British to maintain the position with gun and carriage which they hold with the guns alone, it follows that the recoil is serious, and has to be considered and dealt with. Owing to the use of cordite, however, the recoil of our guns is less than would be expected. It is necessarily, however, considerable. It has been found that the use of drag shoes constitutes the best brake action hitherto tried, and they act with the minimum strain on the wheels. It is to be remembered that the wheels are not made to revolve by the recoil directly, but by the ground holding them and turning them round; consequently a tire brake strains a wheel much less than a nave brake; and of tire brakes, a shoe is one that saves the wheel most completely. To return to the question of efficiency of fire. In number of bullets spread, as well as in accuracy, the British field guns seem to stand first; and if it be understood that the number of rounds stated to be carried in foreign batteries includes, in some cases, some carried in extra wagons in the second line of carriages, it will be seen that in number of rounds per gun we stand first, or nearly first of all. The numbers of rounds per gun are given as follows:—For Horse Artillery: British, 150; German, 126; French, 118; Russian, 75. For Field Batteries: British, 148; German, 109; French, 103; Russian, 63. We have had to lament that in some artillery matters we have allowed other Powers to get somewhat ahead of us; it is satisfactory therefore to be able to speak thus highly of our field artillery at present.

Elements of Descriptive Geometry. By C. W. MACCORD, A.M., Sc.D.; pp. 248 and 280 figs. New York: John Wiley and Sons. London: Chapman and Hall. 1895. 12s. 6d.

THIS is another addition to the already very copious literature of that most popular geometrical study commonly named solid geometry. Several works on mechanical drawing by the same author—notably his "Kinematics"—have previously come under our notice, and the present volume is certainly no exception to the general excellence of these books. The most cursory glance through the pages of the volume before us is sufficient to show how much labour must have been expended in its compilation; and what perhaps makes the work more valuable to engineering students is the fact that the author is, or has been, a practical draughtsman himself, and therefore looks at each problem from an engineers' point of view, with the object of its being utilised in connection with some structure or mechanism The close relationship and mutual dependence existing between the various branches of geometrical or mechanical drawing cannot be too strongly emphasised, although this is so often lost sight of, and we are therefore glad to notice that the author insists on the affinity of descriptive geometry and mechanical drawing, and considers that pupils should have some knowledge of the latter before proceeding to the former. Accordingly, where necessary or possible, the discussion of the problems is divided into parts, in which, under the heading of "Practical Suggestions," the applications of the particular subject in hand are pointed out. The other parts into which the discussion is divided deal more nearly with the geometry of the problem, such as the method to be employed in solving, and the conditions, if any, of symmetry, or of limiting or special forms. If anything, the explanations occasionally become a trifle too solid and profuse, and therefore tend to be somewhat wearying; but in spite of this, they will be of much value to the earnest and more advanced student.

The author fully recognises that with junior students, after they have mastered the projection of the simple solids—with which they are supposed to have already some familiarity—the chief bar to their further progress is the difficulty experienced by the untrained mind in making mental pictures of inclined or oblique planes, &c., when referred to the horizontal and vertical planes. The first chapter, therefore, deals with easy theories of points, lines, and their traces, and gradually advances to problems of more or less difficulty in Chapter II.

Chapter III. forms a somewhat novel departure from the usual beaten track; it discusses generally the generation of such solids as the cone and cylinder, and tangents to these surfaces; which in turn generate the more intricate surfaces of convoluted or screw form. The utility of these considerations will be fully appreciated when studying the succeeding parts of the book, especially Chapter VI. Some of the definitions, however, strike one at first as being unfamiliar; thus, for instance, few English students would know that a "secant plane" is simply a "sectional plane;" or that the word "nappes" takes the place of the usual term "sheets" when applied to different portions of the same surface.

The following chapter is on tangent planes to the surfaces of cones, cylinders, and spheres; these problems, however, do not embrace nearly all those which are usually recognised as presenting difficulties to the student; for although most of these could be solved by the principles considered, reference would need to be made to other works to fully prepare for an examination.

The last three chapters are no doubt the most important from an engineering point of view. Chapter V. gives good illustrations of the intersection of solids and of the development of the resulting sections; but perhaps the most interesting is the next chapter, as it considers much more fully than usual the difficult problems relating to warped surfaces, including the hyperbolic paraboloid, the hyperboloid of revolution, and the helicoid or screw surface. The concluding chapter is, as usual, on isometric drawing; but from the extreme simplicity of this projection there is really no reason why it should not with advantage form the first chapter instead of the last.

The book is very well printed indeed, and the diagrams are simply perfect; the only drawback to the volume is that it contains no exercises whatever, and, as we stated above, the number of selected problems is not nearly sufficient to make up for this deficiency.

SHORT NOTICES.

Engineer Draughtsmen's Work: Hints for Beginners. By a Practical Draughtsman. Illustrations by the Author. London: Whittaker and Co. 1896. Although this is an addition to the many books on this subject, we may say it is one which will be found of practical value to the beginner in the drawing office.

Instructions for Working Plant manufactured by The Brush Electrical Engineering Company Limited. Second edition. London: The Brush Electrical Engineering Company, Limited. Price 2s. 6d.—This little book of instructions is nicely got up, and is illustrated with numerous diagrams. It has value not only to those who have charge of the machinery described, but it has an educational value which is of a practical order. Some of the compilers of a well-known class of cheap text-book will find here instructions for fixing, starting, running, equalising currents, testing, and so on, which will improve several of the works which pretend to go into these matters.

Sewage Purification brought up to date 1896. By E. Bailey-Benton London: E. and F. N. Spon, 1896.—This little book advocates sewage disposal by downward filtration on properly managed farms, and maintains that the cost of coke filters, such as are used by Mr. Dibden, must stand in the way of their adoption. Mr. Bailey-Denton admits that sewage farms are in bad repute, but he attributes this to improper management, and he gives a great deal of more or less detailed useful information about important towns, such as Northampton.

BOOKS RECEIVED.

A Text Book on Gas, Oil, and Air Engines; or Internal Combustion Motors without Boiler. By Bryan Donkin. With 154 illustrations, and selected table of trials. Second edition, revised and largely rewritten. London: Charles Griffin and Co., Ld. 1896.

The London Manual and Municipal Year Book, 1896-7. *Information concerning Public Bodies supplied from Official Sources, or Officially Revised.* Second edition. London: Offices of *London.* Price 1s.

A Practical Treatise on the Otto Cycle Gas Engine. By William Norris, M.I. Mech. E. With 207 illustrations. London: Longmans, Green, and Co. 1896. Price 10s. 6d.

The Facts of Life—Les Faits de la Vie—Idiomatically Described and Systematically Arranged, forming a Complete Dictionary of the Objective Language. Part I., Home Life. The School. Travelling. Plants. By Victor Bétis and Howard Swan. London: George Philip and Son. 1896. Price 3s.

THE FUTURE ROUTE TO ITALY.

WHILE possessing, owing to her extensive coast line and numerous ports, very considerable facilities for traffic and commerce by sea with other nations, Italy is not by any means so advantageously situated with regard to intercommunication with her neighbours by land. Great natural physical barriers and protectors as the Alps are, when viewed from a purely strategical point, they assume a somewhat modified aspect when regarded solely in the light of an obstruction to international intercourse. At present all the traffic in passengers, mails, and merchandise which comes from the Far East, most of which is for the United Kingdom, and are landed at Brindisi, must avail themselves of the French route *viâ* the Mont Cenis Tunnel, which is considerably longer than the one which has for some time been proposed and largely ventilated in public. We allude to the piercing of the Simplon, which it appears is now definitely decided upon, although no actually practical commencement of the great undertaking has yet taken place. It is one of the greatest importance to Italy, as, if carried out, it will unquestionably deprive the present French lines of a not inconsiderable portion of their normal receipts, and divert them in the direction of the new channel. It may be mentioned that the French candidly acknowledge this inevitable result themselves. They may, however, console themselves with the reflection that it will be several years at least before the present project becomes *un fait accompli.* Our neighbours will no doubt make hay while the sun shines. It is doubtful whether Italy is willing, and still more doubtful, considering the heavy demands upon her financial resources, whether she is able to contribute to any great extent towards the expenditure required for an enterprise of this magnitude, notwithstanding its vast future national interest. In the autumn of last year it was stated that the Italian Government would not take any direct part in the construction of the Simplon Tunnel, but would—which is certainly the least it could do—join up its own lines with the Southern Sub-Alpine exit. No contradiction has up to the present been given to this statement. At the same time, when, in the incipient stage of the project, the Swiss Government proposed to place this same end of the tunnel upon Helvetian territory, Italy objected, and insisted upon it being located upon its own soil, and it was under these conditions that their mutual agreement was definitely arrived at.

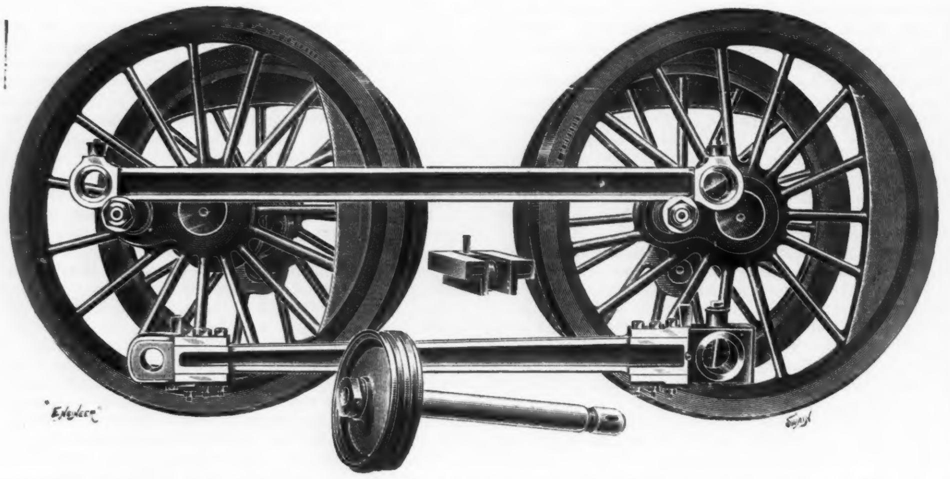
It is not our intention to enter upon any details respecting the character or claims of former plans for achieving the same object, or of the methods for accomplishing it, as they have been in the possession of our readers for some time past; but a brief allusion to some of the superior advantages which the new route can fairly lay claim to with respect to others, both in an engineering and international point of view, may not be without interest.

Between Brigg, in Switzerland, in the Rhone Valley, and Domo D'Ossola, the nearest frontier Italian station, there is really but one mode of communication, which is by the road constructed through the Simplon Pass by the great Napoleon in the beginning of the present century. The tunnel will thus start at a point about a couple of miles from Brigg, and, after passing under Monte-Leone, debouch upon the plains of Lombardy, upon the banks of the river Toce. An international station will be erected on the Swiss side of the Alps, and Isselle has been selected for the site of that on Italian territory. The trace of the tunnel will be rectilinear, always excepting the couple of slight curves at each end, and its total length slightly over twelve miles. It can thus give nearly three miles to the tunnel at St. Gothard, over four to that at Mont Cenis, and is about exactly double the length of that at Arlberg in Austro-Hungary. Although, therefore, longer than its famous predecessors, it compensates for these constructive and financial disadvantages by other merits of its own. It is well known that in mountainous regions the shorter line frequently entails correspondingly heavier gradients, while a longer trace will generally considerably reduce their inclination. Thus, though the shorter line may cost less than the longer in actual construction, the latter will be the cheaper in point of maintenance, both as regards the haulage power and the permanent way, the great items in the estimation of railway engineers and traffic managers. In this respect the Simplon line will be found to score, when compared with the three other examples we have selected. In the first place, it starts from an altitude very much less than that of the other three, which is for the Mont Cenis, 3960ft.; for the Saint Gothard, 3630ft.; and 4290ft. for the Arlberg Tunnel. At its commencement near Brigg, the Simplon Tunnel has an elevation of only 2260ft., reaches its summit level at 2330ft., and drops down to 2190ft. at the Italian terminus. During the first part of the section, the gradient is 1 in 490, and 1 in 140 for the remainder.

The device of running two galleries, and completing for the present only one of them, that is one tunnel, as our readers are aware, will be adopted by the German firm to which the construction of the works has been entrusted, for the purpose of obviating the difficulty, if not the impossibility, of working in the extremely high temperature to which the men will be subjected. At Arlberg the temperature was 64 deg. Fah., at Mont Cenis and Saint Gothard, 86 deg., while it is expected to reach 104 deg. at the Simplon. By frequent cross drifts cut obliquely and connecting the two galleries, it is confidently anticipated that the one will ventilate the other, more especially as the haulage in each will be only in one direction, that is, one track will be the up line and the other the down. By this mode of ventilation, it is calculated that instead of the seventy cubic feet of air supplied per second to the workmen during the piercing of the Saint Gothard tunnel, more than ten times that quantity will be available for the Simplon employés. As one example of the beneficial results which will accrue to Italy from the opening up of the new route, it may be mentioned that the distance between the western districts of Switzerland and Genoa being considerably less than that between the latter town and Marseilles, a portion of the present traffic, which is large, will be lost to that port. Besides, it will be not only the French port which will suffer, but also the French railways in connection with it. So far as we ourselves are concerned, we shall have no cause to murmur. The Simplon route will very considerably shorten the transit from England to Italy, and will bring it within nearer reach of the multitude of English tourists who visit the country and its singularly beautiful surroundings in the summer months.

This example of the value of the new line to Italy is but on a very small scale, and extremely limited in comparison with the ultimate extension and development to which the system might attain. Brindisi, the ancient Brundusium, as already stated, is the most eastern European port open to the traffic of our Oriental dominions, colonies, and dependencies, concerning the annual amount and monetary value of which there is no need of comment. The establishment of Brindisi in 1870 as a principal port of embarkation in the English overland route to the Far East, and subsequently four years afterwards, making it the site of a coaling station for the Peninsular and Oriental Company's fleet of steamers, gave an impetus to the future prosperity of the place, which, to its credit, it has taken advantage of. Since that period, its large and sheltered harbour has been greatly extended and improved, by the construction of two long quays and a breakwater and mole. Mail steamers can now berth alongside the quays with 26ft. of water under their keels, and over a thousand vessels, representing some 650,000 tons of burden, annually avail themselves of the friendly shelter of this important Mediterranean port. A seaport town so advantageously placed, and within sixty hours of London by rail, ought to have a future before it. It is to be hoped that it will—although it may perhaps be going too far, at any rate at present, to hazard the assertion that it will restore the ancient line of communication and commerce between the Far East and the shores of the Western World, and bring back in itself the byegone glories of the once Queen of the Adriatic.

EXPRESS U.S. LOCOMOTIVE—DETAILS



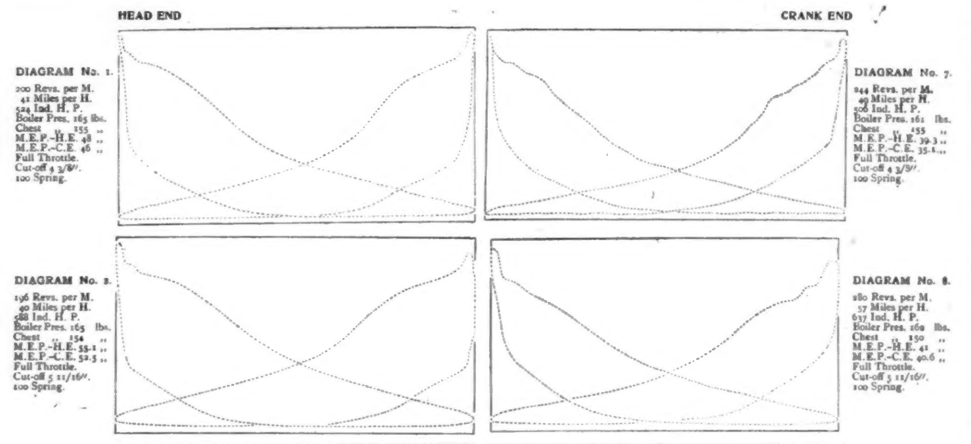
EXPRESS PASSENGER ENGINE, BOSTON AND ALBANY RAILROAD.

We illustrate this week above, and on page 623, a very powerful locomotive built at the Schenectady Locomotive Works, Schenectady, N.Y. Four engines, similar in all respects save one, to which we shall refer in a moment, were built, and put to work last month. The exception is an engine fitted with Fay's valve, which we illustrate fully on the next page. The valve is fitted with Richardson's balancing plate on the back. The general arrangement is no doubt well known to most of our readers. The details are given in our engraving, which has been reduced from the actual working drawing.

The peculiarity of the Fay valve is that, as will be seen from our drawings, passages are made in the cylinder walls, which are opened and closed by the action of the slide valve, the object being to pass steam from one side of the piston to the other, so as to prevent the inordinate compression which takes place when the valve motion is linked up for high speeds.

The result is, of course, that a much "fatter" diagram can be had at higher speeds than is possible without the aid of this simple device. We give a number of diagrams, reduced, which make this very clear. We believe that our engravings are so plain that they do not need any special description to make their meaning evident to any engineer accustomed to slide valve work.

We give a table of the dimensions of the engine, from which it will be seen that it is an enormously powerful locomotive, weighing 53·5 tons, and nearly twice as powerful, indeed, as many English first-class main line engines. The boiler has 2067 square feet of heating surface, and there are 27 square feet of grate. There are no boilers in this country of similar dimensions. The cylinders are 19in. diameter, 24in. stroke, giving a piston displacement of 16 cubic feet per revolution, or $\frac{1}{129}$ of the heating surface, a very large fraction; but to enable the engine to utilise all the steam the enormous boiler can produce the driving wheels are small, being only 5ft. 9in. diameter.



DIAGRAMS SHOWING ACTION OF FAY'S VALVE

The engine is the result of special scheming by the Schenectady Locomotive Works, combined with the suggestions of the master mechanic of the Boston and Albany Road.

Notwithstanding its large size, immense power, and the great speed which it will travel with a very heavy express train, it runs, we understand, very steadily and with little oscillation. The cab is roomy, comfortable, very convenient, and the driver can manipulate this engine with the utmost ease and precision. Its daily duty is to run from Boston to Springfield, and return, 200 miles. For the first 57 miles it has to ascend a grade of 903ft., or say 1 in 334; the remaining 43 miles has a descent of 835ft. It uses two quarts of cylinder oil, three quarts of engine oil, and 3½ tons of coal per day. In stormy weather the amount of coal may be increased. The perfectly satisfactory performance of this engine is largely due, we are told, to the use of the Richardson balanced valve for relieving the pressure of the steam upon the back of the valve, and to the use of the Fay valve for reducing counter-pressure in the exhaust. Speeds of over 70 miles per hour are readily attained with a train of cars weighing 257 American tons without including the passengers. It will easily maintain a pressure of 190 lb. with a heavy train, which is readily understood when we bear the dimensions of the boiler in mind.

As a matter of interest to many of our readers, we give the formula for determining the balancing of the Richardson valve as applied to the Boston and Albany engine No. 273, which we illustrate. The square inches area inside the Richardson balancing strips to be equal to the square inches area of the following named ports and bridges added together:—Exhaust port, one admission port, and both bridges. Thus in engine No. 273 with Fay's valve:—

		Sq. in. area.
Inside of Richardson's balanced strips, 17½in. × 6½in.		105
Exhaust port, 17½in. × 2¾in.	48·125	
Two bridges, 17½in. × 1⅛in. × 2 (bridges)	39·375	
One admission port, 17½in. – 2¾in. : : 14¾in. × 1⅛in.	16·594	104
Difference in square inch area		1

The after end of the boiler is very clear of fittings, being in this respect unlike most English engines. In the upper left-hand corner is the Seabert sight-feed lubricator for oiling the cylinders; a pipe running down the left-hand side carries steam for heating the train; a small gauge on the left-hand side is the steam heating gauge; another on the right-hand side is the air pressure gauge; a small round handle just above the engineers' brake valve operates the sand blast. A small square opening under the front window of the cab is covered with a fine wire screen to keep out cinders and dust. It has an adjustable door, and enables the driver to get fresh air.

Descriptive Specification of Four Eight-wheel Passenger Locomotive Engines for Boston and Albany Railroad.

General dimensions—	
Gauge	4ft. 8½in.
Fuel	Bituminous coal
Weight in working order	120,000 lb.
Weight on drivers	75,500 lb.
Wheel base, driving	8ft. 6in.
Wheel base, rigid	8ft. 6in.
Wheel base, total	23ft. 5in.
Cylinders—	
Dia. of cylinders	19in.
Stroke of piston	24in.
Horizontal thickness of piston	5¾in. centre, 4¾in. outside
Dia. of piston-rod	3½in.
Kind of piston packing	Cast iron rings
Kind of piston-rod packing	U.S. metallic
Size of steam ports	18in. × 1¼in.
Size of exhaust ports	18in. × 2¾in.
Size of bridges ports	1⅛in.
Valves—	
Kind of slide valves, Fay valves in engine 212, Richardson balanced	
Greatest travel of slide valves	5½in.
Outside lap of slide valves	⅞in.
Inside lap of slide valves	line and line
Lead of valves in full gear	1/16in.
Kind of valve stem packing	U.S. metallic
Wheels, &c.—	
Dia. of driving wheels outside of tire	69in.
Material of driving wheel centres	Cast steel
Tire held by	Shrinkage and retaining rings
Driving-box material	Steeled cast iron
Dia. and length of driving journals	8in. dia. × 11in.
Dia. and length of main crank-pin journals	5½in. dia. × 5½in.
Dia. and length of side-rod crank-pin journals	4⅜in. dia. × 3½in.
Crossheads of cast steel, with hollow wings, brass bearings for four-bar guide, upper 4in. × 18in., lower 3in. × 18in.	
Dia. of engine truck wheels	33in.
Kind of engine truck wheels	Furnished by R.R. Co.
Boiler—	
Style	Extended wagon top
Outside dia. of first ring	62in.
Working pressure	190 lb.
Material of barrel and outside of fire-box	Carbon steel
Thickness of plates in barrel and outside of fire-box, 7/16in., ½in., ⅝in., 9/16in., and 11/16in.	
Horizontal seams, butt joint, multiple riveted, with welt strip inside and outside	
Circumferential seams	Double-riveted
Fire-box, length	96 1/16in.
Fire-box, width	40⅜in.
Fire-box, depth	75¼in. F., 63¼in. B.
Fire-box, material	Shoenberger steel
Fire-box plates, thickness, sides 5/16in., back 5/16in., crown ⅜in., tube sheet ½in.	
Fire-box, water space	front 4in., sides 3½in., back 3in.
Fire-box, crown staying	Radial stays
Fire-box, stay bolts	1in. dia.
Tubes, material	Charcoal iron, 12
Tubes, number of	320
Tubes, dia.	2in.
Tubes, length over tube sheets	11ft. 6in.
Fire-brick arch, supported on	Studs Co.'s style
Heating surface, tubes	1912 sq. ft.
Heating surface, water tubes	—
Heating surface, fire-box	155 sq. ft.
Heating surface, total	2067 sq. ft.
Grate surface	26·96 sq. ft.
Grate, style	Rocking, Tupper pattern
Ash-pan, style	Plain
Exhaust pipes	Single, high
Exhaust nozzles	4½in., 4¾in., and 5in. dia.
Smokestack, inside diameter	14in. at centre, 16in. at top
Smokestack, top above rail	14ft. 1½in.
Boiler supplied by two injectors, Mack, class A, pattern of 1882, size 10	
Tender.	
Weight, empty	38,800 lb.
Wheels, number of	8
Wheels, dia.	36in.
Journals, dia. and length	4½in. dia × 8in.
Wheel base	14ft. 6in.
Tender frame	7in. × 3½in. × 1in. angle iron
Tender trucks, side bearing, wood bolster and arch-bar type, B. and A. standard	
Water capacity	4000 U.S. gals.
Coal capacity	8 tons
Total wheel-base of engine and tender	47ft. 3in.
Total length of engine and tender	57ft. 2½in.

Engine provided with—
- American outside equalised brake on all drivers, operated by air
- Westinghouse automatic air brake on tender and for train
- Westinghouse air signal
- Leach sand-feeding apparatus

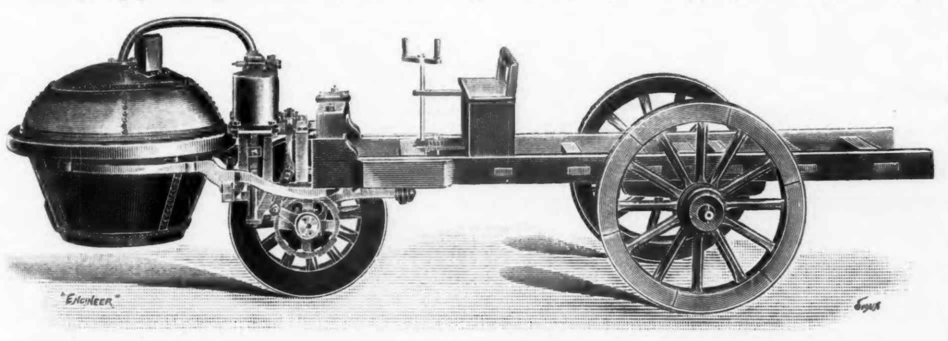
CUGNOT'S STEAM CARRIAGE.

MANY of our readers will be interested in the engraving we now publish of Cugnot's steam-propelled vehicle, with the name and some particulars of which most people are cognisant. An account of the engine and vehicle was given in the "Proceedings" of the Institution of Mechanical Engineers in 1853, page 33, by Mr. E. A. Cowper, and recently we published—page 422—the carefully weighed opinions of its merits and demerits by M. Mallet, who contrasts the work accomplished by Cugnot as compared with that done by Trevithick, the one helped by the State and the other helped by no one. Trevithick was second, but his real success caused M. Mallet to divide the honour between him and Cugnot. Cugnot's old engine, made in 1771, was the first self-moving land carriage ever made, as far as we know. The engraving we publish is from a photograph by Mr. F. A. Field, who writes:—"Being greatly interested in all that concerns locomotive work, I have read with pleasure many numbers of your paper dealing with the historical side of the development of the locomotive, and often wondered why Cugnot's engine should not have had a more conspicuous place therein, but presume that not being a railway machine it might hardly be held to count for much in the history of our railway system. Anyway, an illustration of this venerable auto-car should have found its way to your pages, but I do not believe it has as yet been photographed. Some time ago, being desirous of adding the picture of this engine to my collection, I applied to the Curator of the Conservatoire des Arts et Métiers, Paris, for the necessary permission. No particular objection was raised to the idea of photographing the engine, but apparently it was found impracticable to have it done, as it is stowed away in a rather hole-and-corner fashion in the museum, and much in the dark. I should think, however, if influence could be brought to bear, the obstacles might be overcome, and a very good and interesting photograph obtained. Close by the original, however, is an excellent model, and this was photographed for me, and I send you a copy thereof, trusting it may be of some interest to you. Barring a certain 'newness' of look and excellence of finish, it is an exact copy of the engine itself, and I imagine the photograph I send would make a fairly good illustration for THE ENGINEER." The article by M. Mallet should be read with this engraving as an illustration. Some of his criticisms will then be appreciated.



RECENT IMPROVEMENTS IN DOCKS AND DOCKING APPLIANCES.*

By LYONEL CLARK, Associate.

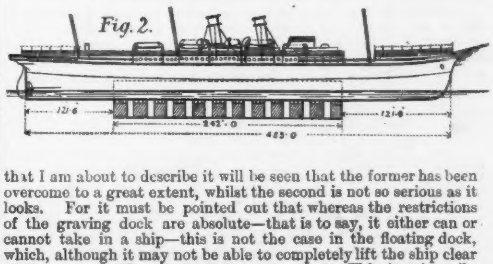
AN historical *résumé*, with which one would naturally commence a paper like the present has fortunately been rendered unnecessary by the previous publication of papers dealing most amply with this portion of my subject.† One point, however, in the history of docks I should like to refer to, and that is, the tendency that is always shown to follow out an existing type, created, perhaps, in the first place by purely fortuitous circumstances, to the complete end. There appears to have been no inclination to take up the subject *ab initio*, to go to the bottom and see how, assuming one's power to be unlimited, one would deal with a ship that required repairing. It is probable that, if perfectly free, we should elect to place such a ship on the level ground close up to our shops; in fact, somewhat in the position in which it was built, but on a level keel. In this position it would be freely exposed to the air, its bottom would dry more quickly, and the paint set harder; we should have the benefit of all possible light, work could be carried on longer without recourse to artificial illumination, and the surveillance of the workmen would be facilitated.

It is quite evident that the ordinary graving dock fulfils none of these desiderata. On the contrary, the ship is at the bottom of a hole, with but little air circulation around it; every piece that requires working has to be lifted out and lowered down again; the size of ship that can be accommodated is strictly limited by the dimensions of the dock, and if it exceed these in either length, breadth, or draught, the dock is as useless as far as regards that ship as if it did not exist. With the advent of the floating pontoon dock, however, many of these disadvantages disappeared. Rennie may be described as the first who introduced this form into practice, and that still lying at Carthagena, and fully described before this society—"Transactions," 1869—may be taken as a type. This dock marked an entirely new departure from the graving dock. The bottom of the ship was no longer got at by shutting it up in a pound and pumping out the water from around it, but the ship was floated over a closed pontoon from which the water was extracted, and which, by means of the displacement thus obtained, raised the ship above the water level.

But with change of design came many other advantages. The ship being supported by the displacement of the pontoon, the water that had to be pumped out from this was proportional to the weight of the ship, and not, as in the case of the graving dock, where the water has to be removed from around the ship, inversely so. Again, the dock was no longer shut in in every direction, but the ends were open, and no gates limited the length of the vessel that could be accommodated. Ships could be taken on and off the dock at all states of the tide, for as the dock rose and fell with the same, the depth of water over the sill remained constant. Even in non-tidal waters the floating dock is more tractable in point of draught, for whereas the depth of water over the sill of a graving dock is rigidly fixed once and for all, the depth of water allowable in a floating dock under normal conditions can always be exceeded in special cases, for no one would hesitate to exceed the normal freeboard and to lower his dock to the very utmost limits if it meant the saving of a sinking ship.

In short, this Rennie dock was already a great advance towards the ideal, its only restrictions being, that the beam of vessel that it could accommodate was limited by the width between the sides, and its weight by the displacement of the pontoon. In the dock that I am about to describe it will be seen that the former has been overcome to a great extent, whilst the second is not so serious as it looks. For it must be pointed out that whereas the restrictions of the graving dock are absolute—that is to say, it either can or cannot take in a ship—this is not the case in the floating dock, which, although it may not be able to completely lift the ship clear of the water, still can raise it to some extent. This fact is strikingly illustrated by the case of the dock we designed for the port of Barrow-in-Furness. This, although of a lifting power of only a little more than 3000 tons, and an overall length of 242ft., was still

Fig. 2.



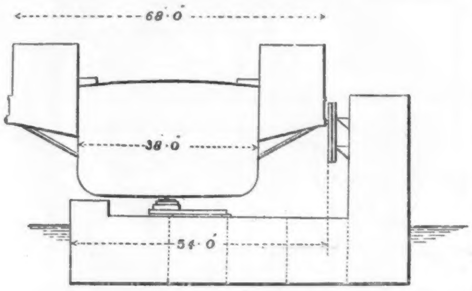
---

* Read at the summer meeting of the thirty-seventh session of the Institution of Naval Architects, June 9th.

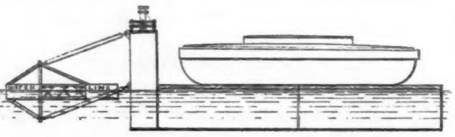
† "Hydraulic Lift Dock," Edwin Clark—"Proceedings" Civil Engineers, vol. xxv., 1866; and "Floating Docks," Sir F. Bramwell—*Engineering*, vol. iii., page 574.

able to lift, and did lift twice, the Empress of China, of a length of 485ft., sufficiently high to allow of her propellers being removed and replaced.

This dock was of a special type, but still an ordinary floating dock could have done the same; but it would, however, have been restricted as to the beam of vessel it could accommodate, and could not have dealt with such a vessel as is here shown, and which was lifted by this same Barrow dock, unless in the first case it had been constructed of an abnormal width and at a correspondingly increased cost. This restriction of beam became a point of capital importance when docking accommodation had to be provided for the circular ironclads of the Russian Navy, of a breadth of 120ft., and which no ordinary dock could then, nor, indeed, can deal with even at the present day.

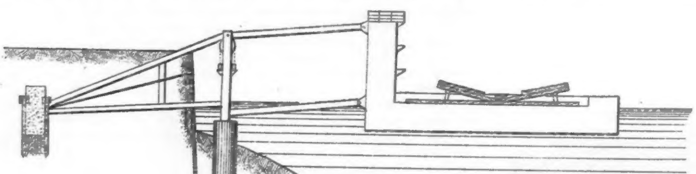


At this time, however, my firm, Messrs. Clark and Standfield, brought out their form of floating dock, known as the depositing dock, and which was described before the present society by my father, Mr. Latimer Clark, F.R.S.—"Transactions," vol. xvii. As this paper is available, I will only say that its chief novelty was the complete suppression of one of the vertical sides, leaving the vessel free to overhang to some extent on the other. The advantage of this power was seen by Admiral Popoff, and we were commissioned to build a dock which should at the same time be capable of lifting the long and narrow vessels of the Volunteer Fleet and the broad circular ironclads known as Popoffkas. This dock was completed at Nicolaieff in 1878, but has since been towed to Sebastopol, in which port it remains in constant use to the present day. This was the first introduction of the one-sided type of dock, and, as in the case of Rennie's dock, other advantages followed from the modification. A most important one was the fact that the removal of one of the sides meant that ships could enter these docks from three directions. They could either come in by the bow or stern, or they could be warped on sideways. In some cases this was more than an advantage, for it meant the possibility of having a dock or not. The dock in this city—Hamburg—belonging to the Reiherstieg Schiffswerfte, although by no means the only example of this, is still a very typical one. The ground at the disposal of this company was such that a graving dock would have cut up their building slips; there was no room for a two-sided floating dock to be moored in the river, and if moored in front of the yard, entry to such a dock would have been impossible. The single-sided dock, however, solved the problem, and the one which you have been able to see was constructed from our plans, and has now been successfully at work for some years.



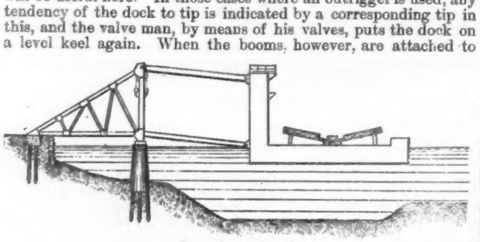
But these one-sided docks also afford important facilities for the easy berthing of vessels. This is well exemplified in the case of the dock belonging to the Smith's Dock Company at North Shields. The graving docks there, as in most other places, are placed at right angles to the river, or nearly so, and therefore an entering ship has to be swung across the strong flowing tide, an operation sometimes of some difficulty. The Smith's dock, however, lies parallel with the run of the tide, and the ship has merely to be sheered sideways on to the dock. No tug is required, but merely hawsers lead to the dock; and, indeed, it would be possible to sheer a ship on to this dock without any extraneous aid whatever. This dock is also interesting as showing the adaptability of the type to any site; both the existing dock and the second one, now all but completed, being placed right inside the river wall, on the site of the old yard, a hole for their reception being cut and dredged out of the river bank.

We have termed this particular modification of our one-sided type of docks the "off-shore dock." It differs from its progenitor, the depositing dock, in the fact that its pontoon is a continuous structure, and not in the form of separate caissons or fingers, and in the fact that stability is obtained by attaching the dock to strong columns sunk in the foreshore instead of to a floating outrigger, although the latter form can be retained, and indeed has been so, in the case of the dock at Stockholm. The details of these columns vary according to the nature of the site, but a few typical examples from actual practice are here appended, showing their adaptability under very different circumstances.

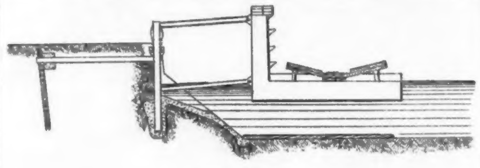


End elevation of Hamburg Dock

A few words as to the practical method of working these docks will be useful here. In those cases where an outrigger is used, any tendency of the dock to tip is indicated by a corresponding tip in this, and the valve man, by means of his valves, puts the dock on a level keel again. When the booms, however, are attached to rigid columns it is evident that there is no means of knowing in what direction the dock wishes to tip until the point of rupture be reached. This is, of course, unallowable, as it is essential in floating docks that the centre of buoyancy be kept under the centre of gravity of the system, by regulating the admission of water into the different compartments; and unless one can see which way the centre of buoyancy is shifting one does not know in which direction to correct it. In the off-shore dock an indication of the tip of the dock is obtained by means of the controlling gear, which is a cam-shaped plate carrying heavy weights, to which the upper boom is pinned, the cam itself being pinned at a different centre to the columns. As the dock tips backwards or forwards, so can the boom swing the cam in and out on the column pin, and thus indicate the direction of heel, which the valve man accordingly corrects by means of his valves. With this exception, the working of these docks is exactly the same as that of any other floating dock, and calls for no special comment.

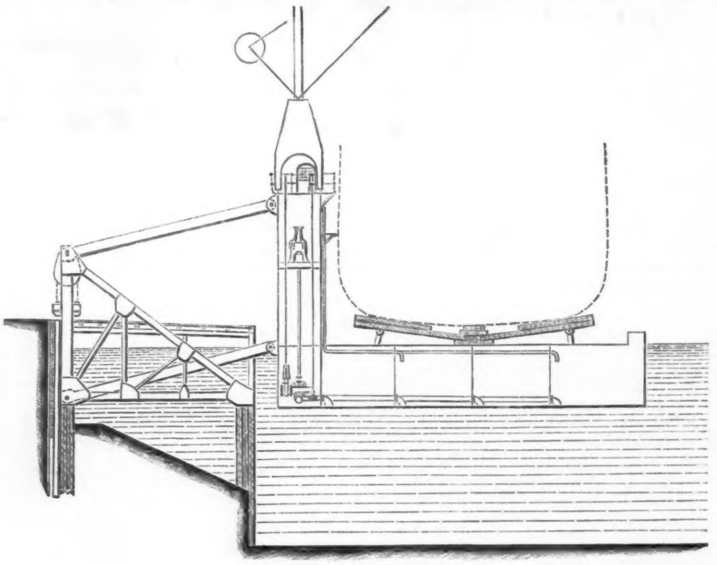


Flensburg Dock



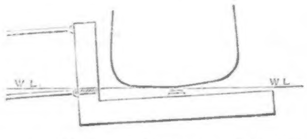
Cardiff Dock

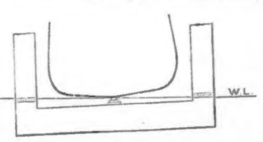
In construction the off-shore dock presents some economical advantages over the depositor and *à fortiori* over the older double-side type. The continuous pontoon is a lighter form of construction than the separate fingers, and the dock has, therefore, less weight in itself to lift at every operation, while the construction of the shore columns compares favourably with that of an outrigger, or of a second side.



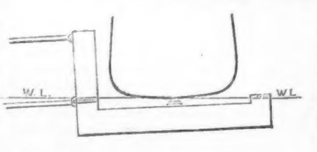
North Shields No. 2 Dock

As a practical advantage, the use of fixed columns permits of a vast increase in the stability of the dock. The question of the transverse stability of this type of dock—for we need not concern ourselves with that in the longitudinal sense—is one of the highest importance, and merits more space than I can spare. Shortly speaking, the tipping moments attain a maximum at a point which we term the critical point. This is when the keel of the vessel is just out of water, whilst the deck of the pontoon remains submerged. It is evident that at this point the whole stability in an off-shore dock must come solely from the shore columns. In a double-side dock we have, under similar conditions, the immersed and emersed wedges of the sides giving us righting moments, but it is easy to understand that the fixed columns afford a much greater resistance than an ordinary side can, and in practice they are constructed to give us about nine or ten times as much stability as an ordinary two-sided dock would have under similar conditions.





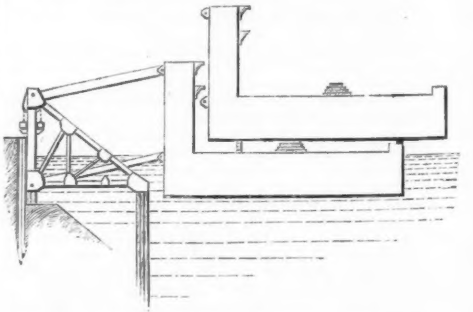
In addition to this, we still further reduce the duration of the critical period, and, indeed, practically suppress it altogether, by means of the "air box." This consists of a light caisson, built along the outside edge of the pontoon, and of a height equal to that of the keel blocks, so that it does not prevent vessels entering the dock sideways. As the dock in working is usually kept slightly heeled backwards, it follows that the top of this box emerges from the water before the inner bilge of the vessel is out, or at least would do so if the dock commenced to tip. The moment the air box emerges, however, it practically converts the dock into a double-sided one. So completely, indeed, is this the case, that I should not hesitate to lift a flat-bottomed craft on one of these docks with the booms entirely removed. This feat, I may add, has been done in the case of the North Shields Dock, where one half was docked on the other before the shore columns or booms were fixed, thus relying entirely on the natural stability of the dock.



But in practical working, of course, we rely on the booms, and look on the air box as merely increasing our factor of safety; and we take advantage of our greatly increased stability to work the dock at a speed which is quite unattainable by any ordinary two-sided dock. For instance, the present Hamburg Dock lifts a vessel of a deadweight of 5000 tons clear out of the water in a space of thirty-two minutes, and that without allowing the dock to get more than an inch or two out of level. In the new or second North Shields Dock this rapidity in lifting has been still further increased, and this powerful machine will lift a vessel of a displacement of 6000 tons, and a draught of some 20ft., in a space of thirty minutes. But the fact that we rely on the shore work for our stability has another advantage, and that is, it permits the reduction of the side to the size required to provide longitudinal stability, and to regulate the descent and ascent of the dock. Since the side is absolutely useless for lifting purposes, and, indeed, on the contrary, has to be carried on the dock and lifted at each operation, it follows that not only is there a saving in first cost by this reduction, but the working cost or power expended in lifting every ship is also less. A further reduction of weight is effected by placing the boilers that drive the dock on shore, steam being conveyed to the engines by articulated pipes. In practice, indeed, the ordinary boilers belonging to the yard are utilised, so that here, again, first cost is saved, and the cost of docking also reduced to the exact amount of coal burnt during the few minutes of lifting a ship.

In the case of the North Shields Dock, still greater economies in weight have been effected, for this powerful machine is driven entirely by the electric current, power being obtained from a central station, which supplies the rest of the yard, and which will eventually drive the first dock also. This very remarkable installation has been carried out under the advice of Mr. Campbell Swinton, and in the Appendix will be found a few notes as to the size and design of what is perhaps one of the largest applications of electricity to the conveyance of power.

I have now to treat of a most important point in connection with these one-sided type of docks generally, and that is the great facilities they afford for a complete self-docking of all their under-water portions. It must on the face of it be evident that a machine built expressly to lift ships can hardly be considered complete unless it can do the same thing to itself. We have always recognised this fact, and all the docks that we have ever designed, of whatever type they may be, possess this power. Indeed, the need of this appears to have been pretty generally admitted, and in most floating docks some approach, more or less successful, towards this facility will generally be found. The one-sided dock is, however, specially adapted for the purpose from its very shape. All that is necessary is to build it in two or more sections, bolted or otherwise connected together, and, when any section is to be docked, the same is unbolted, and floated round over the other section, which then raises it in its lap, so to speak. Such is the procedure adopted in the case of these docks, and the facility with which they can dock themselves is so great that frequent advantage is taken of the same, with the result that their life is thereby prolonged, and one of the most frequent arguments against floating docks is, to say the least, considerably weakened.



But whilst we have been seeking to improve the docks themselves, we have also had to turn our attention to improvements in the gear or fittings of the same. We have found that in many ports where there is great competition there is great demand for rapid lifting facilities, and to meet this we have designed some methods by means of which the berthing of a ship is much facilitated. In the first place, either steam or hydraulic capstans are fitted to the top deck to supplement or replace the ship's own winches. The ordinary method of cutting timber shores to fit each vessel is done away with, and large and powerful shores, actuated by steel worms, pinions, and racks, are contained in tubes let through the side of the dock, and can be rapidly screwed out by means of hand wheels from the top deck. In the case of the new North Shields Dock, hydraulic shores are being provided to deal more rapidly still with the heavy vessels this dock will have to cope with. These shores have other advantages besides those of saving timber. They are marked on their upper side with a scale, so that when the beam of the ship is known, if the shore be screwed out to the corresponding number on these scales, and the ship brought up to them, it is known to be true over the keel blocks. Their strength, too, enables them to be used to push ships forcibly into their correct position, and, in the case of one with a list, they are of great use in replacing it on an even keel.

(*To be continued.*)

ROYAL METEOROLOGICAL SOCIETY.—The last meeting of this Society for the present session was held on Wednesday evening, the 17th inst., at the Institution of Civil Engineers, Westminster, Mr. E. Mawley, F.R.H.S., President, in the chair. Mr. H. Harries read a paper on "Arctic Hail and Thunderstorms," in which he showed that the commonly accepted opinion that hail and thunderstorms are almost, if not quite, unknown in the Arctic regions is incorrect. He had examined 100 logs of vessels which had visited the Arctic regions, and found that out of that number no fewer than seventy-three showed that hail was experienced at some time or other. Thunderstorms were not so frequent as hail; but they have been observed in seven months out of the twelve, the month of greatest frequency being August. Mr. Harries is of opinion that the breeding-place of thunderstorms in these high latitudes is in the neighbourhood of Barent's Sea.

RAILWAY MATTERS.

The jury entrusted with the inquiry into the recent bridge accident at Victoria, B.C., finds that the Consolidated Railway is responsible, and that the Victoria Council contributed to the disaster by its negligence. The verdict is received here with satisfaction. It is likely to be followed by suits for heavy damages against the railway company and the city.

The expedition of Russian Engineers and soldiers, sent from Siberia to China, has, it is stated, nearly finished the survey for the branch of the Siberian line which is to run through Chinese Manchuria, and will materially shorten the distance to the sea. Official Russian reports concerning the progress of the Siberian Railway up to the beginning of this year are very favourable.

It is the opinion of the Federal Council that the Convention between Switzerland and Italy relating to the piercing of the Simplon tunnel should not be formally ratified by Switzerland until the subsidies to be granted by the two Governments shall have been secured. It is said that the Swiss Government will not experience any great difficulty in raising the amount fixed for its subsidy.

The recent report of the Indian railway administration for 1895 shows a great record of progress, as over 800 miles were opened for traffic, while nearly 3800 miles were under construction or sanctioned. The number of passengers carried increased in round numbers by 7,333,000 and the goods traffic by 20,000,000 tons. The net earnings rose 59 lakhs, the total exceeding 14 crores 11 lakhs. The return on capital was 5·78 per cent. Deducting charges for sinking funds and interest on lines under construction, the charge to the State for the whole railway system during the year will be only 76 lakhs, or about half the amount of the preceding year. But for the loss on exchange, a handsome profit would be shown.

The New York, New Haven, and Hartford Railroad Company has recently placed an order with the Schenectady Locomotive Works for twenty heavy passenger locomotives. They are to be of the American type, with 20in. by 24in. cylinders and 73in. driving wheels with steel centres. The engines will weigh about 134,000 lb. The boilers are to be 62in. diameter in the smallest ring, with 312 2in. tubes 12ft. long. The fire-box will be of the "toboggan" type, placed on the top of the frames, and will be 9ft. long and 41in. wide. The boilers are to have an extended wagon top, with radial stays, the dome being on the extension of the wagon top. The maximum travel of valves is to be 6in. The guides are to be of the crocodile form, that is, one bar above and the other below the crosshead. The boilers are made very heavy, with butt longitudinal joints, sextuple riveted. The specifications were prepared by Mr. John Henney, jun., superintendent of motive power of the line. The *American Engineer and Railroad Journal* says the engines will be the most powerful of their class which have thus far been built. The Schenectady Company is also completing five Mogul freight engines for the Maine Central Railroad. These will have 20in. by 26in. cylinders and 63in. wheels.

A meeting of bondholders of the Hudson Tunnel Railway was held on the 11th inst., to consider a resolution for foreclosure and for sale to a new company to be constructed. Mr. H. T. B. Kendall, who was voted to the chair, said the figures were large, but he did not think that without larger figures they could carry the undertaking to a successful issue. There was one feature in the scheme which he was very pleased to refer to—namely, that people in New York now offered to supply half the money that was necessary for completing the tunnel, which would be of immense importance to their city. Mr. H. E. Golding, a member of the committee, stated that the figures now submitted were considerably larger than those previously put before the bondholders. A former estimate put the cost of completing the tunnel at not exceeding £150,000, but that was merely for putting a tube under the river, and not for a completed scheme. The advantage of the present scheme over any other that had been placed before them was that it gave them a commercial undertaking—a tunnel equipped, with the lines through it, and so arranged that it would carry the traffic, immediately it was completed, from New Jersey to New York. Moreover, it was proposed to divert, to some extent, the original route, so as to bring the undertaking in connection with the elevated railway, and thus give an opportunity for through direct traffic from New Jersey to New York. The resolution was carried *nem. con.*

The report of the Electric Traction Company, which was formed for the purpose of constructing the Central London undertaking, the whole of the share capital of which has been subscribed, states that work is being pushed forward as quickly as possible, so that possession of station sites may be obtained to enable the work of construction to be commenced not later than July 1st next. The report adds that the line from Shepherd's Bush to the Bank has been divided into six sections, and on February 19th last a selected number of firms, all of whom were approved by the engineers to the railway company, were invited to tender for the construction of the tunnels and shafts and incidental work in respect of these six sections. A considerable number of tenders having been received, the directors have entered into the following sub-contracts:—Sections 1, 2, and 3, Shepherd's Bush to Marble Arch, Mr. J. Price; sections 4 and 5, Marble Arch to Post-office, Messrs. Walter Scott and Co.: section 6, Post-office to Bank, Mr. G. Talbot. The arrangements with regard to the station at Liverpool-street are progressing satisfactorily. The prices at which these sub-contracts—which cover the principal part of the work of construction have been let, and the cost of acquiring the station sites, are fairly in accord with the estimate formed as to the cost of the undertaking, and confirm the directors' anticipations that the construction and equipment of the Central London Railway will be carried out within the contract price.

In drop-testing machines, such as those used for testing railway axles, it has hitherto been considered that absolute rigidity of the anvil-block support was an essential feature, in order that all the energy of the drop should be exerted upon the axle under test, and none be wasted in compressing or moving the anvil and its foundation. To avoid variable error due to this, Mr. F. D. Casanave, general superintendent of motive power of the Pennsylvania Railroad Company, has reconstructed the drop-test apparatus at the Altoona, Pa., shops by supporting the anvil block on springs. The anvil thus supported offers a constant resistance to the action of the falling weight, when it falls from a uniform height. The anvil is a solid block of cast iron, measuring about 4ft. by 5ft. by 2ft., and weighing 17,500 lb. It is supported by twelve double-coil springs, the outside diameter of the coil being 8in., and the height 9¾in. when open, and 5½in. when closed. When compressed to a height of 7in., the twelve springs will support 80,000 lb. The axle supports are dovetailed into the block, and are placed 3ft. apart between bearing points. The drop weighs 1640 lb., and its maximum height of fall is 43ft. The axle supports are grooved to receive the axle, and the bottom of the groove, in line with the axis of the axle, is curved convex toward the axle to a radius of 5in., so that the axle lies on rounded bearing points. The bottom of the drop weight is also rounded to a radius of 5in., so that it touches the axle only at the middle point. The resistance of the anvil is made up chiefly of the inertia of the mass of iron, weighing 17,500 lb., and the slight movement that takes place is against the resistance of the springs, which is a constant quantity for a given movement. The *Railroad Gazette* says the improved drop offers an opportunity for a comparison of tests made at different times and places, which comparison cannot be satisfactorily made at present on account of the variable condition of the foundations.

NOTES AND MEMORANDA.

The mean temperature of the year 1895 at Greenwich was 49·3 deg., being 0·1 deg. below the average for the fifty years 1841-1890.

In the year ending 1896, May 10th, photographs of the sun were taken at Greenwich with the Dallmeyer photoheliograph, mounted on the terrace roof of the south wing of the Physical Observatory, on 229 days, and of these 459 have been selected for preservation, besides fourteen photographs with double images of the sun for determination of zero of position-angle. For the year 1895 Greenwich photographs have been selected for measurement on 249 days, and photographs from India and Mauritius—filling up the gaps in the series—on 113 days, making a total of 362 days out of 365 on which photographs are available.

It is not a little remarkable that, while the United States are making really considerable advances in the application of machinery to the mining of coal, much less is being done in that direction in this country. A recent official report shows that in the State of Illinois last year the output of coal was 17,735,000 tons, of which 3,531,000 tons were produced by 322 machines. The total number of employés of all descriptions was 38,630, and the total number of boys over fourteen underground was only 811. The *Engineering Review and Metal Worker* says, average value of the lump coal produced in 1895 was only 0·932 dols., or about 46½d. at the mines, and the average price paid for hand-mining was 0·573 dols., or 28½d. per ton.

M. Charles Margot, of Geneva, has recently prepared some interesting aluminium alloys. Thus he finds that 72 parts of platinum and 28 of aluminium give an alloy having a golden yellow colour, whilst other tints can be obtained by varying the proportions of the two constituents. The latter, however, are unstable, breaking up spontaneously. The yellow alloy, on the other hand, is stable, but is brittle. An aluminium alloy containing 75 per cent. to 80 per cent. of cobalt has a colour ranging from straw to brown. It is extremely hard, and will scratch glass, but is very brittle, being easily powdered. Seventy-two per cent. of palladium gives with 28 per cent. of aluminium an alloy having a copper red colour. It is hard and brittle, but stable. With 82 parts of nickel to 18 of aluminium a straw colour alloy is produced, which is as hard as tempered steel, and can resist a hammer blow very well. *Aluminium* says it takes a fine polish, and has a fracture resembling that of bell-metal.

At a recent meeting of the Berlin Physical Society, Dr. du Bois spoke on the magnetising and hysteresis of various kinds of steel and iron, basing his remarks on experiments made in conjunction with Mr. E. T. Jones. The discrimination of different samples of iron by means of their hardness has now lost all its importance; the real criterion is rather hysteresis, coercitive power, residual and maximal magnetisation, which had been determined, together with other magnetic properties, for a large series of samples. Chemical composition is of less importance than the mode of treatment during manufacture from ore to metal. The magnetic constants of the material are of importance to physicists and technologists. The speaker then gave the results of his measurements for three kinds of iron with maximal, and three with minimal hysteresis. As a general rule hardening increases hysteresis and coercitive intensity, whereas residual magnetism is lessened. Krupp's cast-iron is distinguished by its low hysteresis and small coercitive intensity.

In a recent issue of the *Moniteur de la Céramique et de la Verrerie* we find an interesting article by Mr. Leon Appert, the distinguished glass expert, in which he discusses the prominent part which, he thinks, aluminiun is destined to play in the manufacture of glass. "After having made numerous analytical tests of ancient window glass," says Mr. Appert, "I have arrived at the following conclusions, which appear to be of practical, industrial value. The introduction of aluminium into glass prevents or, at least, retards devitrification, which will occur always by the slow and repeated lowering of the temperature. The presence of aluminium makes it possible that a part of the alkaline bases, soda or potash, may be replaced advantageously by an equal quantity of lime. Glass thus modified in its composition is more solid, less changeable, and more elastic. The aluminium can be added to the silica without any inconvenience in a proportion not exceeding 7 per cent. to 8 per cent. The fusibility of glass is slightly increased thereby, while its ductility is not sensibly diminished. The only inconvenience that can arise from the use of aluminium is that it will colour the glass to some extent. This colouring does not result from the aluminium itself, but from the action of the iron oxide, which is always found in it when in an impure condition.

A correspondent of the *Centralblatt fur die Textil-Industrie*, who complains that several belts are dirty from drop oil and dust and desires to know how to clean them, is told by that journal, whose remarks are translated by the *Industrial Record*, to first wash the belts with warm water and soap, using a sharp, stiff brush, and while still moist, to rub them with a solution of sal ammoniac, which saponifies the oil in them. Immediately thereafter the belts must be rinsed well with lukewarm water and then dried with sufficient tension. While they are still moist the belts are to be rubbed well on the inside, and less on the outside with the following unguent: 1 kilo.—2 lb. ¾ oz.—india-rubber heated to 122 deg. Fah. and mixed with 1 kilo. rectified turpentine oil. After the solution is complete, 780 grammes—27 oz.—bright resin are added, and when it is dissolved, 750 grammes—26½ oz.—yellow wax are added. This mixture, by diligent stirring, is mixed with 3 kilos.—6 lb. 10 oz.—fish oil and 1¼ kilos.—2 lb. 12 oz.—tallow previously dissolved in the former. In the further treatment of the belt, rub the inside only and the outside only the first time as stated. This unguent also replaces the tannin extracted from the leather, prevents the dragging of the belt, and imparts elasticity to it.

In a recent paper on "The Relief of the Earth's Crust," by Professor Hermann Wagner, of Gottingen, an abstract of which, by Mr. Hugh Robert Mill is given in *Nature*, some interesting figures are given. By means of the hypsographic curve connecting elevations and percentages of area derived from measurements of height, depth, and area of land and water, the surface of the lithosphere is divided by Wagner into five regions, in place of the three suggested by Dr. John Murray, and hitherto accepted by most physical geographers. The five are as follow:—The culminating area of the earth's crust, occupying 6 per cent. of the surface, and lying altogether above 1000 m., with a mean height of 2200 m., or 7200ft. above the sea. The continental plateau, occupying all the surface from the 1000 m. contour line of elevation to the 200 m. contour line of depth, *i.e.*, to the margin of the shallow sea-border or continental shelf. It comprises 28·3 per cent. of the surface, and has a mean elevation of 250 m., or 800ft. above the sea. The continental slope, from a depth of 200 m. to 2300 m. below sea level, covers 9 per cent. of the earth's surface, and has a mean depth of 1300 m., or 4300ft. The oceanic plateau, between the depths of 2300 m. and 5000 m., occupies no less than 53·7 per cent. of the surface, and has a mean depth of 4100 m., or 13,500ft. Finally, the depressed area, deeper than 5000 m., is assumed to occupy 3 per cent. of the surface, with a mean depth of 6000 m., say 20,000ft. In this classification of regions the coast line is ignored, the abrupt change of slope at 200 m.—or rather the familiar 100 fathom line of our charts—being rightly given the greatest weight in a hypsographic study. The mean level of the surface of the earth's crust is placed by these calculations at a depth of 2300 m., or 7500ft. below actual sea level. The area of the continental block, or region above the mean level of the crust, is found to be 43·3 per cent. of the surface, leaving 56·7 per cent. for the deeper region.

MISCELLANEA.

The Local Government Board have sanctioned a loan of £7500 to Wednesbury for a scheme of sewage disposal designed by the engineer to the Corporation, Mr. Edward Pritchard, M. Inst. C.E., Birmingham.

Mr. Hubert A. Garrett, A.M.I.C.E., Senior Lecturer in Engineering, University College, Bristol, has been appointed head of the Engineering Department at the Northern Polytechnic Institute, Holloway, London, N.

The applications of compressed air have become so immense in the United States that a monthly periodical has been started entitled *Compressed Air*, devoted to the useful applications, amongst which in No. 2 are sheep shearing, underground tramway working, compressed air in work shops, machine shops and foundries, and brakes.

A very interesting table of wheat prices appears in the Minnesota labour statistics lately compiled. In 1867-70 it is shown that the British miller paid 175·6 cents for Minnesota wheat, of which the North-Western farmer received 65·3 cents, the difference, 110·3 cents, being what was absorbed by dealers, middlemen, and transportation companies. This difference declined to 32·7 cents in 1887-90, the price for the farmer being 73·4 cents.

In the United Kingdom, Germany, Belgium, and the United States most, if not the whole, of the coal consumed is of native production. Of Russia's consumption 79 per cent. is her own coal, 17 per cent. is British coal, and 4 per cent. comes from other countries. In Sweden 88 per cent. of the coal consumed is British, in France 12 per cent., in Spain 50 per cent., in Austria-Hungary less than 1 per cent., and in Italy nearly the whole is of British origin.

The use of a channelling machine to open trenches in asphalt pavement is being attempted by Wilson and Jackson, contractors, of Chicago. This firm has secured a channelling machine built by the Sullivan Machinery Company, of Chicago, and will use it in cutting through the asphalt and macadam roadways which are being trenched for the electric wire conduits of the new electric lighting system now being constructed by the West Chicago Park Commissioners.

On the 15th inst. a traction engine, belonging to Mr. Roger Fenton, of Torquay, was going down Fore-street, Teignmouth, when, it is said, the driver lost control of it, and the weight of three trucks of bricks which were attached gave it such an impetus that it went through a confectioner's shop window, demolishing the side wall and the entire window. A little girl named Waite, about six years of age, ran into the doorway, and was killed instantly.

The annual conversazione of the Society of Arts was held last evening in the galleries of the South Kensington Museum. Over two thousand invitations were issued, and a very large concourse attended. The guests were received by the chairman of the Society, Major-General Sir J. Donnelly, and the members of council. Promenade concerts were given by the band of the Royal Artillery in the North Court, and by the Red Band in the Textile Court, and entertainments were given in the Lecture Theatre.

In these days, when so many railroads are built on paper alone, it is refreshing, says the *American Manufacturer*, to note the beginning of a project which is to be put through. Such is the new Butler and Pittsburg Railway, which was organised a few days ago. Mr. Andrew Carnegie, chairman of the Board of Directors, has subscribed 2,500,000 dols. of the 3,000,000 dols. required to build this road. This line, although short, will be a very important one. Its entire length will be but forty miles. It will run from the Edgar Thomson Steel Works, at Braddock, to Butler, where it will connect with the Pittsburg, Shenango, and Lake Erie Railroad. Its route will be along the Alleghany River to Deer Creek, and up the creek straight to Butler. This line will doubtless have an influence on the ore carrying trade, as it will furnish the Pittsburg district another outlet to the lakes. This road will further assist Pittsburg in meeting that fast-growing tendency to move the iron manufacturing industries towards the lake region.

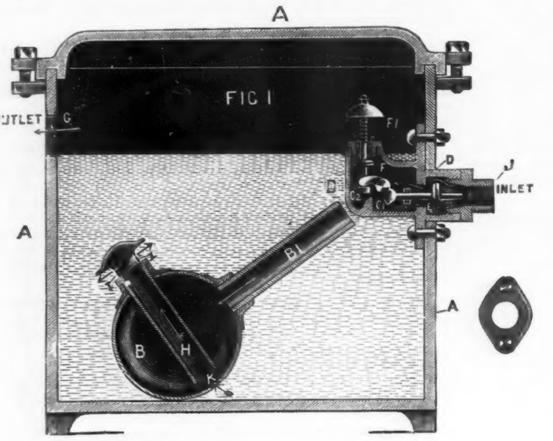
The first cotton spinning factory in Japan was erected in Satsuma by Prince Shimazu Narihisa. In 1850 he established a scientific laboratory in his grounds, and encouraged investigations in Western medical and chemical sciences. He took a great interest in photography, telegraphy, glass making, and gas manufacture. Three years later he established a workshop near his summer villa, in which he made many experiments in machine and engine construction. He also erected at Niriiso, a suburb of Kugoshima, a spinning factory, which still stands, and in which there are 3000 spindles in operation. The machinery was supplied by Platt Brothers, and was fitted up with all the best appliances of the time. The enterprise was started without any thought of profit-making, and everything was done on an elaborate and expensive scale. An Englishman was engaged as superintendent. The yarns soon obtained a high reputation, and were employed in weaving the well-known cotton fabric of Kuagoshima, *Satsuma kasuri*.

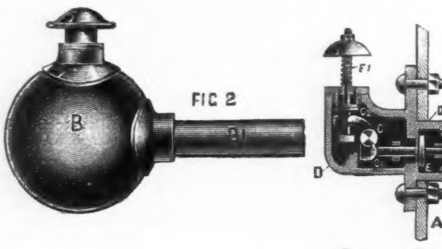
A sudden stop to the machinery at the Star Manufacfacturing Company, Ramsbottom, was recently caused by the breaking of the main driving belt. This belt is 30in. wide, and transmits about 300-horse power, which drives 700 looms and preparing machines; the driving wheel is 27ft. in diameter, and weighs 25 tons, and the velocity or speed of belt is 4100ft. per minute. It was at once concluded in the mill that the engines had broken down, but they were found to be working at the ordinary speed, without any load upon them, or in any way whatever damaged. After two days' stoppage for piecing the belt the machinery was again set in motion. The engines are horizontal compound side by side, made by Messrs. William Sharples and Co., Ramsbottom; they are controlled by their automatic crank-shaft governors, which are connected direct to the expansion valves in the steam chests, and no doubt prevented a very serious accident. It would be interesting to know the condition of the belt and what was the nature of its breakage; a pull of about 80 lb. per inch of width is not heavy.

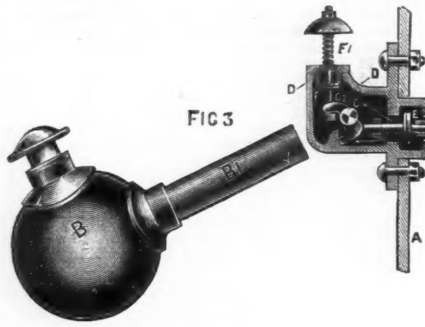
In moving the second reading of the Floods Prevention Bill on Tuesday, Lord Thring said that it was a very simple measure. It was not intended to deal with great calamities, but was intended to provide the local authorities with moderate powers for preventing floods in cases where no such power could be exercised at present. It was a permissive Bill, and proposed that where there were no drainage areas the county council might have power to remove obstructions, repair works, facilitate the passage of water, cleanse watercourses, &c. There was no compulsory power of rating. The county council might, if it thought that it would be for the benefit of the county, pay the expenses out of the county rate, or, if the local authorities were willing to consent and desired to be assisted, the charges might be made partly on the locality and partly on the county. After some remarks by the Marquis of Salisbury, Lord Thring said he should in Committee move to insert a clause saving all the conservancy boards and all elected drainage boards, and it was not intended to interfere with the existing drainage areas. The Marquis of Salisbury said he did not suppose such an idea would cross their minds, but if the County Council were disposed to make a new bid for the river Thames it would be in their power to do so under this Bill. He had no cause to think that any county council would go so far mad, but still the powers were very extensive, and rather in excess of the modest language used by the noble lord. The Bill was then read a second time.

A NEW STEAM TRAP.

THE accompanying illustrations show the construction of a new steam trap now being introduced by Mr. Edward Yates, New Mills, Stockport. It is claimed that this steam trap is essentially distinct in principle from all other traps. When steam is turned into pipes or apparatus that this steam trap is connected to the action is as follows:—The copper ball float B is at the bottom of cistern A, and causes the cam C 1 to hold open the entrance valve E and cam C 2 to hold open the air valve F against the pull of the spring F 1; these cams are on a pivot C in the small valve and cam chamber box D, and are connected to float B by float arm B 1; the air which always comes first is blown away through the air valve F into cistern A, and then away through the outlet G instead of entering the float and causing it to rise prematurely, as is the case with some other traps. The water will next flow through the valve E into the chamber D, and down the elbow pipe B 1 into the float B, up the down pipe H and through the outlet holes I into the cistern A, and away through the outlet G. The steam at last follows the water, and as the area of the steam inlet valve is greater than that of the air valve, the air valve cannot pass the steam admitted by the inlet valve, so it at once forces the water out of the float up the down pipe and leaves it buoyant. It immediately rises, Fig. 2, relieving the position shown in the cams from the valves and allowing the pressure to close the valve E, and the spring F 1 to close valve F without loss of steam, or hammering of the valve faces on the seating. There is a small hole K in the bottom of the float B, which begins to fill from the water in the box A, consequently destroying its buoyancy and causing it to fall and force the cam C 1 against the entrance valve E and push it away from its seating. If live steam be there it will at once rise and allow valve E to close again as before without loss of steam, but if water be present it will receive it all. Cam C1 operates on the entrance valve E first, and will discharge all the water without disturbing the air valve whilst working, and only open the air valve when the apparatus is stopped.







Its action is similar to that of a man standing by a wheel valve and keeping it open so long as condensed water is flowing out, closing it as soon as steam appears, slightly opening it again to see if there is any more condensed water, and if so keeping it open and allowing all condensed water to escape, and closing it as soon as steam commences to appear, and so on alternately.

THE METRIC SYSTEM IN OUR WORKSHOPS: WILL ITS VALUE IN PRACTICE BE AN EQUIVALENT FOR THE COST OF ITS INTRODUCTION?*

By COLEMAN SELLERS.

IN view of the movement which has recently been made to establish the metric system by compulsion in this country, we think the following paper, by a very eminent American mechanical engineer, will be read with much interest. The paper was written twenty-two years ago, but nothing has occurred since to alter the facts or modify Mr. Sellers' line of reasoning:—

IN compliance with the invitation of the General Supervisory Committee, as expressed through your secretary, that, as an associate member of the American Railway Master Mechanics' Association, I should prepare a paper on some subject relating to the objects for which this Association has been organised, I have decided to call your attention to a matter which may before many years be forced upon you, and which you should be prepared to consider with care; I allude to the proposed introduction, by legislative enactment, of the French system of measurement, known as the metric system.

It is not my intention to discuss the subject in all its bearing, for it is a theme requiring more pages of manuscript than I would care to inflict upon you. But I will state in as few words as possible how the proposed change would be likely to affect the workshops of the land. It is now about three-quarters of a century since the metre was first made the legal standard of length in France, and during that time it has been adopted by other countries, either in full or in part, so that the advocates of its universal adoption claim that the proportion of the population of the globe already enlisted in its use numbers 420,000,000. Hence they argue that, for the sake of a uniform metrological system all the world over, England and the United States of America should also adopt it to the exclusion of our present system of inches, feet, &c.

Many of our leading colleges are making the metric system the method of measurement in all their teaching, with a view to sending their graduates into the world as advocates of what to them seems so perfect a system.

There can be no doubt that it is very desirable to have uniformity, not only in regard to measurements of all kinds, but also in money, as such uniformity would certainly facilitate trade and advance our knowledge of the works of other countries. Those who use the metric system in all scientific matters find it wonderfully well adapted to facilitate calculation. In spite of its long names, it is easily understood by persons of moderate education, and can be used even by those who have no idea of the Latin and Greek words from which the names are derived. If the world, as we know it in our arts and trades, was to be made over again, and we were obliged to adhere to ten as the base of our arithmetic, it would doubtless be a good thing in some respects, but very unhandy in more respects, as not admitting of binary division. I have heard it declared by men of high intelligence that its introduction now is retarded only by prejudice, by the unwillingness of people to give up what they are used to, and the necessity of learning certain new rules and methods of thought. Unfortunately, maybe, there is something more than these objections that will retard its introduction. The change involves the expenditure of money—of very large sums of money. When this cost is presented to our minds, we may well consider whether the results to be obtained will warrant the expenditure.

The late Senator Sumner was its earnest advocate, and at one time was determined to push the adoption of the metric system. He said to one of our most distinguished scientists, "I am content to have it legalised in 1870, and to have its use then optional, but in 187— I would make its use compulsory." The gentleman to whom he addressed himself asked if he had well considered what a tax such a measure would impose on the country. "We have now in use," he said, "in all kinds of trades, the pound as our unit of weight, and Messrs. Fairbanks and other scalemakers have for years been making platform scales with beams graduated to pounds. The edict that abolishes the pound will necessitate a change in all these machines for weighing. All their beams must be removed and regraduated to the new unit at an enormous expense." He instanced the change in the weight unit as the one most readily made, as it in the main affects perishable property only.

On February 8th, 1870, a resolution was passed in the United States Senate, that "The President be requested, if not incompatible with the public interests, to invite a correspondence with Great Britain and other foreign Powers with a view to promote the adoption, by the Legislatures of the several Powers, of a common unit and standard of an international gold coinage," &c. In accordance with the spirit of this resolution, a dispatch was prepared by the Department of State.† In this paper, after recounting the requirements of such a unification in coinage as shall not prejudicially affect our interest, it says:—

"It is to be observed that an identity in the measures of value in the different countries will not completely attain the beneficent results which are sought, unless there be also an identity in weights and measures. . . . In commercial transactions an identity in measures of value would be of comparatively little use if unaccompanied by identity in the measures of the quantities to which those values are applied. There would still be a necessity for the intervention of an expert to shift the expressions of the measures of quantity from the terms used in one country to those in use in the other. The resolution of the Senate does not contemplate the extension of this correspondence to these points, nor, in my judgment, would it be desirable to do so.

"It would probably not be difficult to induce the people of different countries to adopt a common standard of weights and measures so far as perishable property is concerned. At first the adoption of unaccustomed systems might cause inconvenience and discontent, but if they should prove to be better than the old ones, and if they should have the further advantage of being common to several countries which possess a common standard of value, and which have extended commercial relations, it is probable that the inconvenience would be patiently submitted to, in view of the greater benefits to be derived from the change.

"But it seems to the Government of the United States that a forced change in the measures of distance, as applied to imperishable property and the permanent investment of capital, may be attended with more serious inconvenience. Thus while it may be practicable to establish a new standard of length-measure for articles of international commerce, such as textile fabrics which are consumed and do not remain, it may be more difficult to make the same change in the standard for permanent values. A few examples will demonstrate the difficulties that would probably attend a change in such measures in this country. . . .

"It is the custom in the United States to lay out all towns and cities in regular quadrangles, and to divide each quadrangle into an even number of lots with an even number of feet. This has been found a convenient mode of dealing in town and city lots and in town and city houses. To make an arbitrary change, which should abolish these measures and substitute different ones in their places, involving the use of fractional numbers, would occasion great inconvenience, and might check the dealings in this species of property, and cause a loss to those who happened to be holders at the time of the change. Again, the whole system of titles in those states which have been created out of the public domain rests upon Government survey, whose results are expressed in the English mile and its subdivisions, rods, feet, and inches. To substitute a different measurement would be a work of serious magnitude.

"Again"—and this is what most seriously affects our interests—"the manufactories of the country are filled with machinery, whose delicately adjusted parts, measured in feet, inches, and component parts of the inch, work together in one grand whole, which is in its turn combined in the same system of measures. To produce this machinery, thousands of shops are filled with costly plants, adjusted upon the same scale, whose delicate operations often require a nicer determination of measurement than can be obtained without mechanical aid. To transmute these measurements so delicate and accurate from the present system into a new one, would appear to be an almost endless labour, if indeed it be a possibility."

To show how clearly these statements express the difficulties that would attend our adoption of the metric system, I will call your attention to certain conditions of the mechanic arts in America, perhaps not fully appreciated by those who think the change is one of education only.

Eli Whitney, whose name has always been associated with the invention of the cotton gin, started in 1798 an establishment for the manufacture of small-arms on the principle known as the interchangeable system, carried out by the use of hardened jigs or forms of the same shape as the parts to be produced, thereby making all parts of guns alike and interchangeable one with another. He introduced the use of milling by means of revolving cutters, those intricate shapes needed in gun work. When he proposed to Thomas Jefferson, then Secretary of State in Washington's Cabinet, to make an arm modelled after the approved French Charville flint lock, in which all parts of all guns should be interchangeable, he was ridiculed by both French and English ordnance officers. The Government aided Mr. Whitney, and in 1800 the Springfield Armoury was established, and Mr. Whitney's inventions and system put in force there. It was not until 1855 that the English War Department was forced to adopt the same system, importing a large amount of machinery from America for that purpose.

This was not the only branch of the mechanic arts that was benefited by this interchangeable system. America, contending with high labour, has been forced to exercise ingenuity, and make labour-saving machines produce cheaper work. This could only be done by carrying the interchangeable system into other processes of manufacture, and American clocks, watches, sewing machines, and all the countless small articles of hardware, are made by machinery, each piece like the others. Recognising the absolute need of this interchangeable quality in everything manufactured, but few trades exist in this country that do not avail themselves of its advantages. Gradually, separate and distinct manufacturing establishments have come to use the same standards and to make their production interchange one part with another. Witness the various devices making up what is known as line shafting, as also all the screws and fittings for steam, gas, and water pipes, and now the so complete recognition of the American system of screw threads for bolts and nuts. The primary object of this Association may almost be said to be to introduce uniformity in all parts of the great railroad system of the United States. There is no country in the world where the value of uniformity in the devices used in common by all mechanics is so fully recognised as in this land of ours. What has been done in this direction, and what is being done now, is founded on the inch as the unit of measurement in the machine shop.

The machine shop, however, is not independent of other trades, and it is necessary to a proper understanding of our subject that we have a clear perception of the nature of this interdependence. Machines made of metal have parts cast and parts forged. Wrought iron is procurable in bars of certain merchantable sizes. When rolling mills are obliged to make round iron, differing in diameter from these merchant sizes, the price per pound is increased as special appliances and extra care is required. So the mechanical engineer conforms his proportions to the procurable sizes of bar iron, and uses the iron, as far as possible, without the expense of re-forging into other sizes. This is noticeably the case in regard to rounds and squares. The tools and appliances in the machine shop have in time been made to conform to these sizes, and are all expressed by the division of the inch into halves, quarters, eighths, and sixteenths. All the gearing in the country, all the patterns of cog-wheels, are spaced in the teeth, by pitches, measured in inches, and the binary division of the inch, ¼in., ½in., 1in., 1½in., &c., pitch; or, in number of teeth to the inch in diameter, called in practice per inch wheels, as 12, 10, 8, or 6 per inch, meaning so many teeth to each inch in diameter; as, for instance, a wheel 3in. in diameter cut to ten per inch, has thirty teeth, *i.e.*, 10 × 3 = 30. The patterns of gear wheels in some instances form no insignificant part of the stock-in-trade of large machine shops, and the immense number of wheels now spaced to pitches in inches must necessitate the continued use of them, whether we call the pitch 1in. or 25·38 mm.

When the metric system was introduced into France, all machine work was done by hand; the planing machines for metals, and all the various appliances known as machine tools, with the exception of the turning lathe, were almost unknown. Sizes expressed in one measurement or another were of less moment than now. I dare say many of my hearers remember the time when the rule-of-thumb was the mechanic's rule; when the "boss" chalked out on the carpenter's bench a thing about "so big," to be made in metal, and then some other thing was made to fit it; at such time it mattered little what standard was used as measure. While French *savants* were labouring to build up this decimal system of interchangeable measures, the better class of American mechanics were solving the problem of making machinery with interchangeable parts. I am perfectly willing to concede that there are workshops in the land in which the change from the inch to the metre could be made at very little cost, simply because these shops are furnished with no special devices for measurement even at this day; such drills and mandrils as they may have are altered in size at the whim and fancy of the workmen. The proprietor of one of this class of shops asked me not many years ago if we had a pattern of a spur wheel of some pitch and diameter, and when I asked him if he had measured the diameter at the pitch line of the wheel, he wanted to know what the pitch line meant. Metres would do for that man quite as well as inches. Such machinists, in stating dimensions, use the terms "full" and "scant" to express fractions which might be quite readily stated with accuracy; sometimes, however, indulging in the extra expression of a "leetle full scant" for very nice measurement.

A well-furnished establishment is provided with gauges, mandrils, reamers, standard drills, and boring tools, as well as all other appliances needed for accurate work made to certain fixed sizes, and in most shops these special tools amount in value to large sums of money. The nomenclature of the sizes of these tools, as expressing the work they are expected to do, is part of their economical use; thus, an inch reamer is expected to make a hole exactly 1in. in diameter, and no great effort of memory is needed to designate its size, but this same inch reamer will make a hole 25·38 mm. in diameter, which is the same size expressed in French measurement.

In the machine shop the unit of measurement is the inch; it is not the foot nor the yard. We express in inches all measurements of objects that may sometimes be made less than 1ft. in size. Thus, pulleys are rated as 5in. or 10in. or 72in. in diameter. Boilers are spoken of as being 36in., 42in., or 48in. diameter. Car wheels are 30in., 32in., or 36in. in diameter. For all calculations in the drawing-office we use the inch and its decimal divisions, corresponding exactly with our dollars and its division into halves, quarters, eighths, and sixteenths. As in money, we say half a dollar or 50 cents with equal facility, so in measurement we have the ½in. or ·50in., each as expressive of size as the other.

(*To be continued.*)

† See "U.S. Report on Foreign Relations for 1870.'

A NEW LUBRICANT FOR RAILWAY AXLES.

THE Ministry of Prussian State Railways is conducting elaborate tests of a new composition for lubricating the axles of railway wagons. The Minister of Railways takes the liveliest interest in these tests, which are made with the usual exactness of the Prussian officials. The following is a summary of the results obtained from official sources.

On January 27th, 1896, Corridor Car No. 562 was selected by the Directory at Halle, by order of the Minister of Railways, and the new composition applied to its eight axle-boxes. The method of application was to impregnate sixteen cushions, such as are ordinarily used on railway wagons in Germany, with the composition, rendered liquid by heat, and to place two in each box under and over the journals. In addition, some of the composition was put in each box. The total weight of the lubricant applied was 16 kilos. The car was put on the regular train service between Berlin to Frankfurt-on-Main, starting from Anhalt Bahnhof. After running 5000 kiloms. a slight addition of lubricant was made in each axle-box. At the end of 30,000 kiloms. run an official inspection was made at Berlin, and a report submitted to the Minister of Railways.

It was found that the total weight of lubricant which had been applied during the running of 30,000 kiloms. was 31 kilos. The cushions were taken out of the axles-boxes and weighed, and the grease remaining in the boxes was also removed and carefully weighed, the total being 25·700 kilos. The net weight of the cushions without grease was 4·160 kilos., and 1 kilo. of the grease, which had become blackened by the dirty oil formerly used was discarded. The remaining 20·540 kilos. were returned to the axle-boxes and new composition added. The net consumption for the 30,000 kiloms. run was taken at 10·540 kilos. A second and a third test of running 30,000 kiloms. followed in succession, and the consumption was found in each instance to vary but slightly from 10·460 kilos. for each 30,000 kiloms. run. Altogether wagon 562 ran between Berlin and Frankfurt-on-Main, 90,000 kilos., and the total consumption was 31·400 kilos., which is at the rate of ·349 grammes per kilom. run. The same car is now running on the fourth test of 30,000 kiloms., with like satisfactory results. After the first run of 30,000 kiloms, and cleaning out the boxes there has been no discoloration of the composition. A third cushion is put in each box to fill the space at the ends of the axles because it is found unnecessary to have so great a quantity of the composition in the boxes; and by this means it is also found that the boxes can be made dust and dirt-proof.

Making the comparison as to cost for lubricant with the cheapest oil sold in Germany, 20 Pf. per kilo.—the price of oil actually used by the State railways being considerably more —the saving, according to the official figures, in material cost per vehicle comes out at marks 15·84 per each 30,000 kiloms. run, or about 53 Pf. per each 1000 kiloms. But the saving in cost of material is not all, since no labour is required, and no time consumed in examination and in applying lubricant except at the end of each 5000 kiloms., when the boxes are opened, and a slight addition of the composition made. The severest cold known in Germany does not affect the composition, as its freezing point is - 28 deg. Cent. On the other hand, the melting point is so high that the warmest weather ever known there will not cause it to run. There is not the slightest dripping from the boxes, and consequently no waste. In over 100,000 kiloms. run by wagon 562 there has not been the slightest indication of heating of the axles.

Reducing the foregoing metric figures to English weights and measures, the results come out approximately as follows:—One application of the composition suffices for a run of 3100 miles of train service, and in running 18,600 miles eight axles consume less than 23 lb. of the lubricant, which is about 1½ grains per 100 miles run for each axle-box. The saving in material cost, as compared with oil of the cheapest German quality, is 10¼d. per 1000 miles of train service for eight axle-boxes.

USE OF ELECTRICITY ON BOARD SHIPS.*

By HERR F. EICKENRADT, Engineer Inspector.

IN endeavouring to comply with the flattering request of speaking before this assembly, I have chosen for this purpose a subject which at the present time should engage the attention of shipbuilders in general, viz., "Use of Electricity on Board Ships." First of all, I beg leave to request the distinguished company here assembled not to criticise my statements with the eye of the technical electrician, as I do not pretend to pose as a specialist in this subject. I rather shall endeavour to treat the question merely from the point of view of the shipbuilder. Excepting in isolated cases of minor importance, electricity has only been recently brought into more extensive use for working auxiliary machinery on board of ships. Not only has the technical electrician endeavoured in the last few years to interest the shipbuilding industry in the application of electricity, which took such enormous strides in its development, and to draw the equipment of ships into the province of their commercial supplies, but also the shipbuilder—whose work may be described as a rallying point of every new technical invention developed to its utmost extent and completeness, and who is thereby obliged to follow every further step onward with ever-watchful eye—could not afford to neglect the obligation to make a practical test of the value of the electric motor on board ships.

The first question, from the point of view of the shipbuilder, was to ascertain whether electricity, as such, had special advantages to offer over steam power, hitherto generally employed. This question may be answered with a decided "yes" in many cases. The large number of auxiliary engines which are in use on board modern steamers, and still more so on men-of-war, not only as accessories to the complicated main engines, but also for all other possible purposes, necessitated the laying of steam pipes into almost every nook and corner of the ship, both for the purpose of bringing steam power to the spot, and for carrying away the waste steam after use, a fact which does not exactly contribute to the comfort of the crew. This network of pipes produces, notwithstanding the most careful covering with non-conductors, not only troublesome and unnecessary heating of spaces where it is not required, but leads to still greater inconveniences in consequence of the damages to which such steam pipes are unavoidably subjected. The leaking of a single flange may make staying, even in large rooms, perfectly impossible. All these evils are avoided if the transmission of power to the different points for use is effected by a wire, which, when properly adjusted as to dimensions and well insulated, has absolutely no effect upon its surroundings. The second question is, whether the electric motor is superior to the steam motor. As to this, it must be admitted that a steam engine in every part of the ship is disagreeable; it emits heat, and is exposed to many accidents, which may produce detrimental, and, in some cases, even disastrous effects to its vicinity. Such accidents do not arise to the same degree with the electric motor, besides which it has the advantage of being very simple to manipulate, as long as it is at all efficient for use, and, what is especially of importance for the circumstances on board ship, it is much more clean to handle than a steam engine.

I make this reservation with the electrical motor "as long as it is efficient for use." This point appears of importance in regard to its usefulness on board. The electric motor has, however, hitherto remained quite unknown to the engine-room *personnel*. They are not sufficiently familiar with its arrangement, especially with the often very complicated supplementary contrivances, and they do not know what to do when a breakdown occurs. On the other hand, it must be admitted that the technical electrician has already recognised this fact to a certain extent, and has provided for it, partly by simplifying every apparatus which will have to be entrusted to unskilled hands as much as possible, the reliability of the working of which has to be safeguarded under any circumstances, and partly by excluding those parts which do not require special attention from any possibility of being touched by incompetent hands. Supposing that a motor has been constructed, in this respect, with the most complete perfection, the only attention it would require would be that, at certain intervals it is necessary to inspect the bed-plates, and to ascertain the condition of the insulation in the wires. With such simple attention it becomes possible to supervise several motors, which are worked from a common centre, by a very limited number of hands, which undeniably is a great advantage.

I shall now proceed to consider successively the following subjects, viz., installations for lighting, ventilation, and heating, ships' winches, ammunition supplies, appliances for moving guns, and steering apparatus.

Lighting.—When electric lighting was first introduced, there were indeed many opponents, but to-day its abolition is beyond any discussion. Its reliability of working is fully safeguarded with the dynamos in use at the present time, and any danger of fire is as good as excluded, when the installation is properly and scientifically made; therefore the advantages of electric lighting are now so generally acknowledged that even on small cargo steamers, where only a limited number of lamps are required, a small dynamo engine is installed for lighting purposes. Electric lighting installations are indeed reckoned amongst the sanitary fittings of ships, and while mentioning this we are involuntarily driven to the question whether in this respect further improvements might not be obtained by means of electricity. In answer to this question we are led to consider ventilation and heating apparatus.

Ventilation.—Good ventilation on board, both for living rooms and cargo spaces, may now be considered as a generally admitted necessity. But every shipbuilder is aware of the difficulties which the solution of this question presents in regard to natural ventilation, and artificial ventilation has therefore taken its place everywhere on board already. An arrangement of tubes emanating from a central point and leading into every part of the ship would appear to be the most advantageous. However, the carrying out of such a system would be connected with enormous difficulties, considering the circumstances on board ship, and having regard to the conditions which would have to be fulfilled in order to make it efficient; and especially taking into consideration the necessity of preserving the water-tightness of the bulkheads, which would absolutely forbid the passage of air tubes through them. The shipbuilder is therefore obliged to divide the entire system of ventilation into several parts, each independent of the other, and must make allowance for the division of the ship into water-tight compartments. For the working of these separate ventilators, which frequently have to be fitted up in out-of-the-way corners, which are difficult of access, a steam engine has to be again supplied, to which the evils previously enumerated are especially applicable, and which necessitates again a special attendance. For the working of such ventilators, therefore, the electro-motor is excellently adapted, and its driving may be effected from any easily accessible place with the same facility as if it were situated in the immediate vicinity of the ventilator. The kind of motor here in question is of very simple construction, does not require any complicated auxiliary arrangements, and will keep on running without any attendance at all. If there are not many ventilators of large dimensions to drive, the installation of a separate current circuit may be avoided, and the ventilators may be connected with the circuit for the lighting, for which purpose the latter will only experience an immaterial addition to its weight. Should there, however, be several ventilators with fans of 800 to 1200 mm. diameter, and demanding a current of 2000 to 4000 Watts, it is preferable to establish a separate circuit for them.

With regard to the advantages of the electro-motors for this purpose, it is anticipated that they will be generally adopted for the driving of ventilators, and this may occasion, again, an improvement of the systems of ventilation, as they may be extended to spaces which hitherto have been excluded. Also, the ventilators for the stokeholds of boilers under forced draught having a consumption of energy of from 15,000 to 20,000 Watts each, and the engine room ventilators with a consumption of 6000 to 10,000 Watts each, are advantageously driven by electro-motors, because every unnecessary addition of heat to these rooms, which are already very hot in themselves, should be avoided, and because the installation of the ventilators in the heating rooms is often such that the attendance upon a steam motor is thereby made very difficult. In places like the above, where the electro-motors are exposed to the particularly severe effects of coal dust and heat, it is further advantageous, for the maintenance of the good condition of the motor, to construct it inside the suction tube of the ventilator, which can easily be done in centrifugal ventilators, with separate air suction tubes; by such an arrangement the electro-motor will be well protected and kept cool.

Electric heating.—Very little experience is available up to date in respect to electric heating, and, as far as I know, experiments in this direction have only been commenced at a very recent period. Installations for this purpose would offer a great advantage, by enabling us to dispense with the very extensive pipe system required for the steam heating process, with its innumerable flanges, taps, valves, and condensing pipes, all of which details occasion frequent inconvenience, in consequence of leakages and failures in the action of the condensing apparatus. Many perforations through bulkheads are also dangerous inconveniences. All these evils would be avoided in electrical heating, the conducting wires for which could be suitably joined to those for the lighting apparatus with the object of minimising weight and restricting the number of conduits generally, as much as possible. The disadvantage of such an installation consists, however, in the fact that a comparatively large main engine for the generating of current would have to be erected, and that this force would only be fully employed while the limited period for heating lasts. If you take it for granted that a steam heating apparatus with heat-giving copper tubes and a total heating surface of 75 square metres would produce hourly a heat 60,000 calories, an electric heating apparatus of the like power would require a main engine of about 75,000 Watts power, consequently a steam engine of about 100-horse power. The erection of such an engine exclusively for this purpose would, however, only very rarely be suitable for ships. But in case an electric motor is contemplated, say, for boat-hoisting apparatus, &c., which would not be often in use, and then only for a short period, the necessary engine for this purpose might in the interval be used with great advantage for heating. Electric heating all over a ship can, therefore, at present not come into consideration, but it might be advantageous for many spaces where electric lighting has already been resorted to, and where a connection with a steam-heating system presents other difficulties. I should like to mention here that the preceding remarks have been based upon a supposed transmission of 800 calories per hour and per square metre of copper tube in the steam-heating surface. Absolute reliance, however, cannot yet be placed on these figures, and likewise the transmission co-efficients have not yet been exactly ascertained which have to be taken into account for circumstances on board ship. The introduction of electric heating on board, which requires an exact previous calculation of the heating surface and of the dynamo engine, still necessitates, therefore, the investigation of the above-mentioned transmission co-efficients on existing steam-heating installations.

Ships' winches.—The manufacture of electric ships' winches forms already a special department with the electrical engineering firms. They are now so thoroughly understood in all their branches that their general adoption for ships may be confidently anticipated in the near future. The excellent results which many German firms have also shown in this branch have further induced them to go a step forward from the comparatively simple winches for loads up to 2000 kilos. and 3000 kilos. to the heavy boat-lowering winches with a lifting capacity of 10 tons to 16 tons. Such installations, which require a development of force equal to 90 to 100-horse power, can, however, only be advantageously employed when the electro-motor has been adopted for all the auxiliary machinery in a ship. In an installation of this kind it is not requisite that the power of the main engine equals the sum total of the capacity of all the auxiliary engines; the calculations must rather be based upon the total of all the engines which may be in use at the same time. During the period of employment of a boat winch of 50-horse power, which is driven by a central engine, it will always be possible to disconnect a corresponding number of other machines, such as ventilators, pumps, &c.

Ammunition hoists or lifts.—The adoption of electric agency for many motors upon men-of-war appears already of paramount necessity. The working of the great number of ammunition hoists which have become requisite through the ponderous modern armaments, with numerous guns, would necessitate a very large quantity of small but fast-running steam engines, the service of which would unavoidably lead to a considerable increase of engineer hands. The installation of electric motors, driven from a central station and requiring no particular attention and care, seems, therefore, advantageous for this purpose; the more so, as in special cases they are adapted to be fitted in very small dimensions, whereas a steam engine would always occupy a much larger space. If the ammunition supply is not effected by Paternoster appliances, but by lifts, the motors are, however, no longer so simple in their construction as those mentioned before. In the hoisting by lifts, the chairs have to be attached in such a way to the motor that the latter at the ends of travel is automatically stopped and set in motion. Besides, an electric brake must be provided, and by means of special minor appliances the quiet starting of the chair must also be guaranteed. However, there are already numerous installations of this kind in existence, and their efficiency has been proved by practical experience, from the results of which the general adoption of electrical energy for the ammunition hoists may be considered as secured in the near future.

Gun and turret turning.—The manufacture of electrical turning appliances has lately occasioned a lively rivalry; yet, up to date, it cannot be asserted without a doubt, that they will supplant the approved appliances of hydraulic power. Considering the paramount importance of these appliances for men-of-war, the fact that the question has been technically solved in the most complete manner does not only appear to be decisive, but every chance of the gear getting out of order must be practically excluded, and the crew for this service must be so completely familiar with its working that they are able, not only to guarantee its expert handling and the maintenance of its efficiency, but also, in case of need, are able to repair and make good any damage. The current circuit in such installations must of necessity be very complicated, so that a quick detection of any sudden damage requires in any case considerable technical knowledge, especially with regard to the fact that faults in such electrical installations often, unlike those in mechanical appliances, do not show on the outside, but remain hidden in the circuit. In consideration of the necessary shortness of this paper, I must deny myself the pleasure of entering more fully upon particular installations, and I will only state that, with parallel arrangement of the motors in one circuit current, thus avoiding a current of high tension, the connection with the general electro-motor installation and their driving from the general central station can very well take place.

Steering apparatus.—The steering apparatus offers the greatest difficulties for electrical application; but, on the other hand, this makes it one of the most interesting subjects. Before going more closely into the matter of electrical application, I will shortly explain the steam steering gear hitherto in use, in so far as it is necessary for the comprehension of the electrical appliances. The steering gear with its appurtenances may be divided into three separate parts, viz., into the motor proper for working the rudder, into the arrangement of the motor for setting it in motion from the deck, and into the arrangements of the motor for stopping it after the rudder has been moved. In the steam steering apparatus with mechanical appliance for setting it in motion, this is often done by means of a hand wheel, which is fixed on the bridge, and which is turned in correspondence with a scale for bringing the rudder into the desired position. The turning of this hand-wheel turns at the same time a transmission system laid through the whole ship, and moves also, by means of a worm fitted to the end of the transmitting crank, a nut which is in connection with the steam inlet valve, and which thus opens it. By these means the motor proper is put in motion, and causes, by means of the turning of the motor crank, a self-acting return motion of the nut, and places the valve again into its position of rest. As soon, therefore, as the hand-wheel on deck ceases to be turned, the motor will immediately stop itself through its own movement. Every shipbuilder, however, knows the great difficulties caused by the laying of such a long transmission system which has to be worked by hand. Even although the mounting has been successfully completed, it will often happen, after the vessel has been running a short time, that the transmission can no longer be moved, a fact which is due to the contraction and expansion of the bulkheads and decks to which the blocks have been fixed. With the electrical installation, the question is whether the motor, or the moving appliance, or the stopping appliance alone, or the whole apparatus shall be driven electrically. As far as I am aware, the use of electricity for such an entire gear has hitherto not been attempted. In most cases electricity has only been employed for the starting appliance. A combination of the starting appliance with a self acting registration upon the control board on deck by the electric current from the tiller has, however, proved to be so difficult that to judge from what has hitherto been achieved in this direction, we can hardly expect a solution of this problem, at present, which will be satisfactory and always reliable in its action. As it stands to-day, this question allows only the installation of an electrical starting apparatus, which generally is restricted to a common governing apparatus, and which only supplies the current to a comparatively simple electrical apparatus, which in its turn again controls the steam inlet valve. The closing of the valve must then be effected by cutting off the current by means of a separate indicator with a hand showing the position of the rudder, which in its turn again is set in motion by the tiller direct. This apparatus may again be either mechanical or electrical, and several reliable electrical apparatus for this purpose are already in existence.

A very interesting starting appliance, as used on the French cruiser Bouvines, is described in the *Révue Maritime et Coloniale*. Here the distributing valve of the steam steering apparatus is not automatically moved by the apparatus itself, but by a small electrical motor, quite independent of the steering gear, and the latter follows the movement of the valve. The starting of the motor is done from the deck by means of a governing apparatus. Here, however, the current is not led direct into the motor, but first to a relay, which then in its turn governs the motor current. The working of the governor apparatus on deck is effected according to a rudder indicator, which contains several numbered lamps. These different lamps correspond with certain rudder angles, and are lit up by the movement of the tiller. Such lamp signals, which also are employed for engine telegraphs, have, however, the great disadvantage that the different signals which are indicated by the simultaneous burning of different lamps are difficult to distinguish in strong sunlight. It is also very misleading when the different lamps burn with different degrees of brightness, and a failure in consequence of a lamp burning out is also possible.

---

* Read at the summer meeting of the thirty-seventh session of the Institution of Naval Architects, June 18th.

If the construction of an electric motor for the steering gear does not at the first glance seem to present any particular difficulties, these are indeed very material. A reversible motor requires a governing apparatus, which must be of very substantial construction, if it is not to be speedily used up, or if undue heating of the same is to be avoided, regard being had to the size of the motor and to the fact that it may have to be worked, perhaps, 1000 times in a day. A continuously running motor, which only moves in one direction, requires again the insertion of electrical couplings for the turning of the tiller to the right and left. The suitability of such couplings for frequent in and out turning has, however, still to be demonstrated. The employment of two constantly moving motors, which work by means of a differential wheel appliance, demand the manufacture of very excellent wheels, if this apparatus is not to work too noisily. This latter machinery is at present in construction in Germany, and the result may be watched with great interest. However, all these contrivances have the disadvantage that they necessitate a very well trained *personnel* for their effective working and keeping in good order. If, therefore, as may with confidence be expected, electrical power is introduced on board ship to a greater degree, the special training of the crew in its use will be unavoidable.

Concluding remarks.—At the close of my remarks I will only touch upon a general question, which is of importance for electrical installations on board. With the increasing employment of electricity on board ship the question arises, whether for such installations continuous or alternating currents should be chosen? In all installations hitherto made, the continuous current has been exclusively used; it has proved completely efficient, and there has been no occasion to discard it, as long as there was only a question of illuminating the interior and of search lights. The latter can only be worked with continuous currents, otherwise their lighting power would suffer a decrease of about 40 per cent. As, on men-of-war, the consumption of energy for the search lights reaches the considerable extent of 20,000 to 70,000 watts, it is evident that, for the kind of current required for lighting the interior, and for several small motors, continuous current only can be utilised. The injurious influences upon the compass may be avoided, with such a current, by careful disposition of the leads, and the scientific construction and fitting-up of the dynamo engines. But when it comes to a general introduction of electromotors for working the auxiliary machinery, and a central station is erected for this purpose, which, like one already in construction in Germany, works with a power of 300,000 watts, the employment of continuous current offers considerable difficulties. In particular, the motors placed on deck for the gun-turning apparatus and ships' winches have to be placed in such dangerous proximity to the compasses, that the disturbing of the latter in the case of parallel current can hardly be prevented. For the working of this machinery, therefore, the use of the alternating current becomes unavoidable, as such a current, and likewise any motor driven by it, has no influence upon the compass. This, however, again, necessitates the erection of two central stations—viz., one for the search lights, and lighting, with parallel current; and a second station, with alternating current, for driving the auxiliary machinery. Unfortunately this arrangement presents the great disadvantage that the motors for one station cannot be employed in support of, and in substitution for, those of the other; and that thereby a great complication would be created for the whole installation, which would demand greater capabilities from the crew. It will be impossible, however, to avoid this if the increased advantages, which the use of the electrical appliances affords on board of ships, are to be secured.

LAUNCHES AND TRIAL TRIPS.

ON Wednesday, the 10th inst., the s.s. Ashby, just completed by Messrs. Ropner and Son, of Stockton-on-Tees, to the order of Messrs. R. Ropner and Co., West Hartlepool, left the River Tees for her official trial trip. On the arrival of the vessel in the Tees Bay her compasses were duly adjusted, after which a very satisfactory run was made, the machinery working very effectively and easily. After the trip the steamer proceeded on her voyage to Bilbao.

Messrs. Wm. Simons and Co., Renfrew, have launched complete a single screw hopper dredger constructed to the order of the Wexford Harbour Commissioners. This vessel is of the following dimensions:—Length, 120ft.; breadth, 28ft.; depth, 10ft. 6in. The Slaney is capable of carrying 250 tons deadweight, and is propelled by one pair of triple surface condensing engines of indicated horse-power sufficient to propel the vessel, when fully loaded, at a speed of 7 knots per hour. The hopper compartments are provided on each side of well, having all the necessary gear for lifting and lowering the hopper doors. A steam crane is provided at after end of hopper for emptying the hopper when filled with ballast.

On the 12th inst. Messrs. Sir Raylton Dixon and Co. launched at their yard, Middlesborough, the steam collier Zuid Holland. This vessel has been constructed for the special duty of carrying coal from this country to the Continent, and will be fitted also with powerful lowering appliances. The dimensions are as follows:—Length, 229ft.; breadth, 34ft.; depth moulded, 17ft. 6½in. She will be supplied with a set of triple expansion engines by the North-Eastern Marine Engine Works Co., of Sunderland, having cylinders 19in., 31½in., 51½in. by 36in. stroke, which will take steam from two single ended boilers 11ft. 9in. diameter, and 10ft. 6in. long, with a working pressure of 170 lb. The vessel will have the highest class at Lloyd's, and is being built from the designs and under the superintendence of Messrs. Flannery and Tritton, of Liverpool and London.

On the 10th inst. the s.s. Borgom was launched from the yard of Messrs. Sir W. G. Armstrong and Co. She is a steel single deck tank steamer for carrying petroleum in bulk, and also case oil, for the economical loading and discharging of which special arrangements of winches &c, have been made. Her dimensions are as follows:—Length, 320ft.; breadth, 42ft.; depth moulded, 22ft. 2in. The engines will be of the triple expansion type by the North-Eastern Marine Engineering Co., of Sunderland, having cylinders 24in., 40in., 64in. by 42in. stroke; they will take their steam from two single ended boilers 15ft. 3in. diameter, and 10ft. 6in. long, with four furnaces in each boiler so arranged that residuum may be used as fuel. The vessel has been constructed from the designs and under the superintendence of Messrs. Flannery, Baggallay and Johnson, of London and Liverpool, for Mr. A. Mantachaff, and is of large carrying capacity. She will be supplied with a powerful pumping system for the quick discharge of liquid cargo. Her electric lighting installation has the latest improvements, and is fitted throughout the vessel.

On the 13th inst. there was launched from the Queen's Island yard of Messrs. Harland and Wolff the P. and O. ship China. The launch was timed for eleven o'clock, and punctually at that hour the magnificent vessel began to move along the launch ways, and a few minutes later entered the river opposite the Belfast shipyard. The launch took place without the slightest hitch. The China is the fifth steamer built on the Queen's Island for this company, and is 500ft. in length by 54ft. beam. She will have two masts, and schooner rigged. Her gross tonnage is about 8550, and she will be propelled by a single set of triple-expansion engines of 7500 indicated horse-power, which are being constructed by the builders of the vessel at their engine works at the Abercorn Basin. The captain's and officers' cabins, the chart-room, and wheel-house are on the boat deck, and the accommodation for first and second-class passengers—of which she will carry a large number—on the hurricane, spar, poop, main, and lower decks. The ship will be fitted as a first-class mail and passenger steamer, and will have a full installation of electric light, also refrigerating chambers for cargo and stores, hydraulic deck machinery, &c.

On the 12th inst. Messrs. Ropner and Son, of Stockton-on-Tees, launched a steel screw steamer of the following dimensions, viz.:—Length between perpendiculars, 270ft.; breadth extreme, 39ft. 6in.; moulded depth, 17ft. 6in.; which they have built for Mr. Christian Klaveness, of Christiania. The vessel is built as a part awning decked steamer with raised quarter deck; her deadweight carrying capacity being 2625 tons on 17ft. 7½in.; the saloon and cabins for captain and officers, also the engineers' accommodation being fitted in deck-houses amidships. She is built on the web frame principle, leaving the holds entirely clear for cargo, and carries her water ballast in a cellular bottom, and in the after peak. All labour-saving appliances are fitted for the economical working of the steamer, and also for the expeditious loading and unloading of cargoes; she has steam steering gear amidships and screw gear aft, four powerful steam winches, a large multitubular donkey boiler, direct steam windlass, stockless anchors, &c. The engines will work up to about 900 effective horse-power, and are by Messrs. Blair and Co., having cylinders 20in., 33in., 54in., by 36in. stroke, steam being supplied by two large steel boilers working at 160 lb. pressure. The name of Kingswood was given to her as she left the ways.

On Friday 12th inst. Messrs. John Scott and Co., of Kinghorn, launched the first of the two new paddle steamers which they are building to the orders of the Wallasay Urban District Council, under the superintendence of Messrs. Flannery and Tritton, consulting engineers of Liverpool and London. These vessels are 160ft. overall by 27ft. beam by 10ft. 6in. depth moulded. They have been built with all the latest improvements, and have been so arranged that the funnel stands amidships, and gives two long unbroken saloons fore and aft, and there is no obstruction by the funnels in the gangways. The vessels are also fitted with two rudders and steam steering gear, the levers for the same are grouped together with the telegraphs in a convenient position at the mate's platform, which is situated forward of the funnel, and gives the steersman an uninterrupted view ahead. The vessels are constructed to carry 1500 passengers on a very light draught of water, and to maintain a higher rate of speed than the present vessels engaged in the same service. The comfort and convenience of the passengers have been especially considered, the saloons being thoroughly heated and ventilated, and tastefully decorated. As the vessel left the ways she was named the John Herron, in honour of the chairman of the Ferry Committee, by Mrs. Finch, the wife of Mr. F. Finch, of the firm of A. Bellbourough and Co., of Lloyd's. The chairman and a large company of ladies and gentlemen were present at the launch. The vessel will shortly proceed upon her official trials, and take her station on the Mersey.

On the 15th inst. the fine screw steamer Ragnar left the port of Hartlepool on her trial trip. The Ragnar has been built by Messrs. Wm. Gray and Co., to the order of Mr. L. H. Carl, of Copenhagen, and to Lloyd's highest class. Her length over all is 285ft.; breadth, 39ft. 6in.; depth, 19ft. The deck erections consist of poop, raised quarter deck, and partial awning deck. A handsome saloon, state-room, and accommodation for captain and officers have been fitted up in the poop, and comfortable quarters for the engineers amidships, and for the crew forward. The hull is built with web frames and cellular double bottom, and with large ballast tank in the after peak. Four steam winches, large patent donkey boiler, steam steering gear placed in the engine-room casing, hand screw steering gear aft, direct steam windlass, schooner rig, boats on beams overhead, grain divisions, and all improved appliances for working the steamer have been provided. The engines are of the triple-expansion type, and have been supplied by the Central Marine Engine Works, of Wm. Gray and Co., the cylinders being 21in., 33in., and 56in. in diameter, with 36in. piston stroke, and steam is supplied by two large steel boilers working at a pressure of 160 lb. per square inch. When opened fully out the engines ran 83 revolutions per minute, for trials on the measured mile they were reduced to 75 revolutions, when the mean speed was found to be 10·3 knots per hour, on a low coal consumption. The trials were highly satisfactory, the engines running without trouble or hitch of any kind, and the boilers remaining quite steam-tight. The trial was witnessed by Mr. C. Nielsen, J.P., Danish Consul, Mr. Hans Neilsen, Mr. Chas. Nielsen, and Mr. Albert Trechmann, of West Hartlepool; Mr. Knutzen and Captain Nordahl, of Sunderland; Captain Murrell representing the builders of the ship, Mr. Mudd on behalf of the engine builders, and Miss Mudd. The vessel and her machinery have been constructed under the personal supervision of Captain Jorgensen, who has also gone to sea in command of the ship. On the conclusion of the trial the vessel discharged her passengers to tug in Hartlepool Bay, and proceeded to Sunderland to take in her first cargo. The Ragnar is the second vessel built and engined for Mr. Carl by Messrs. Wm. Gray and Co., being a sister ship to the Sigurd, recently sent to sea.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

THE demand for steam coal is very good, and the shipments of the past week were above the average. Prices firm. The house coal trade keeps up fairly well for the season, and prices show no alteration. Tin-plates in demand, with prices very firm. The iron and steel works continue well employed at full prices.

Coal: Best steam, 8s. 6d. to 8s. 9d.; seconds, 8s. to 8s. 3d.; house coal, best, 9s. 9d. to 10s.; dock screenings, 5s. 3d.; colliery small, 4s. 6d. to 4s. 9d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 46s. 7d.; hematite warrants, 47s. 5d. f.o.b. Cumberland; Middlesbrough No. 3, 37s. 6d. prompt; Middlesbrough hematite, 44s. 9d. Iron ore: Rubio, 12s.; Tafna, 11s. 6d. Steel: Rails, heavy sections, £4 12s. 6d.; light ditto, £5 to £5 5s. f.o.b.; Bessemer steel tin-plate bars, £4 2s. 6d.; Siemens tin-plate bars, best, £4 5s., all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel, coke, 9s. 3d. to 9s. 4½d.; Siemens, coke finish, 9s. 6d. to 9s. 7½d.; ternes, per double box, 28 by 20c., 19s. to 20s. 6d. Pitwood: 16s. to 16s. 3d. London Exchange telegram: Copper, £49 10s.; Straits tin, £60 15s. Freights steady.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK.

THE commercial situation has grown worse for a week, and prices for many commodities have declined. Railroad earnings are 2½ per cent. ahead of last June. Bank clearings 14½ per cent. below last year, but this is partly due to the absence of speculation. Commercial failures are numerous, and show that the pressure on credit is severe. Currency is flowing from the interior at the rate of one million pounds a week. Large gold exports continue. Interest is growing in the political conventions to be held soon, and until the Republican convention at St. Louis is held there will be no move in business. The immense crops give a strong tone to the markets. Coal mining is not restricted, and prices keep up well. Coke production at Connelsville is one-third less, but price is two dollars. New coke fields will soon be producing. A few blast furnaces have been damped. Stocks will not be permitted to increase much more. Bridge works have lately booked large orders for material, and managers look for a steady influx of orders. Structural material will maintain its advance on small buyers. Skelp iron makers have lately added large orders on their books. Merchant iron is dull, and merchant steel active. The wages question in the rolling mills is now up for its yearly adjustment, and will be amicably disposed of. The tin-plate manufacturers are putting their industry into good shape for future harmony. Building operations are progressing finely in all sections. There is great activity in the gold regions of the Rocky Mountains, and both home and foreign capital is finding welcome and profitable employment.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

ON 'Change to-day—Thursday—in Birmingham the improved tone manifest last week continued. Sheets are very strong, and the prices of doubles is quoted £6 15s., an advance of 2s. 6d. on the week, in consequence of the hot weather having necessitated the mills in some cases being put to stand. Some brokers ask as much as £6 17s. 6d., but this is an outside price, and is obtained in very few instances, consumers reminding sellers that a week ago the open market quotation for doubles was £6 12s. 6d. per ton. Lattens are quoted £7 7s. 6d. to £7 10s., the merchants in certain instances demanding £7 12s. 6d. Sellers here and there quote singles £6 15s., but the price is rather a long one, and there are makers who will not hesitate to accept £6 10s. Some of the largest sheet iron firms in this district having as many as twelve mills running are full up with work, and are not at present anxious about adding to their orders. The galvanisers are also full of work. Galvanised corrugated sheets, f.o.b. Liverpool or equal, are priced at £10 5s. to £10 7s. 6d. for 24-gauge, and quotations are supported, not only by the excellent demand, but by the high price to which spelter has risen. Sheets from Wales for bucket-making are quoted up by merchants 7s. 6d. per ton, and japanners' sheets for trunk making are quoted by middlemen £7 15s. doubles, and £8 10s. lattens. Sellers of bar iron of common and medium qualities are attempting a rise of 2s. 6d., and occasionally 5s. per ton, as the result of the meeting of the Unmarked Bar-makers' Association last week, when such an advance was declared justifiable. The Unmarked Bar Association's price for common bars is now understood to be £5 7s. 6d. to £5 15s. per ton, while merchant bars are £6 to £6 5s., and marked iron is £7 to £7 12s. 6d. nominal.

Excellent reports were brought to 'Change this afternoon of the activity which now characterises some of the wrought iron tube works in the district. Good shipping orders have been booked by certain of the biggest firms. Gas tube strip is quoted to-day £5 7s. 6d. to £5 10s. per ton; hoops are £6 7s. 6d.; and thin strip £6 10s.

The pig iron trade rules strong. The quieting down of a couple of months or so back has given place to a resumed active inquiry, and everyone is busy. Good quality Northamptonshire and Derbyshire forge pigs are quoted an average of 41s. delivered to works in this district, less 2½ per cent., and Lincolnshires—forge—44s. delivered at stations in this district, net cash. Foundry iron of No. 3 Northamptonshire quality is about 43s. 6d. per ton, and Lincolnshire foundry 45s. 6d. Staffordshire pigs are quoted, cold-blast, 90s.; all mine, 55s.; part mine, 40s. to 42s. 6d.; and cinder about 35s.

Steel makers keep busy in all departments; in truth, the managers of some of the largest works this afternoon spoke of themselves as "terribly busy." The activity reported from the other steel centres all over the country is fitly reflected in the condition of local works, both the melting and rolling plants being run at their fullest capacity. The indications are all in the direction of a continuance of the present activity. Bessemer billets and tin bars delivered into this district, from the North of England and South Wales, are quoted £4 2s. 6d. to £4 5s. net, and other descriptions go on up to £4 10s. and £4 12s. 6d. The plants of the Patent Shaft and Axletree Company, Wednesbury; of the Staffordshire Steel and Ingot Iron Company, Wolverhampton; and of the Earl of Dudley's works at Brierley Hill, are all fully engaged, and there is every prospect of all the steel works in the district being fully employed up to the end of the year.

The mechanical engineering trades continue active, both for export and also on local orders connected with factory extensions. The railway rolling stock branch is supported by large Indian and South African orders.

The information is received in this district with much satisfaction that the engineering and kindred trades continue well employed in most branches throughout the kingdom, the percentage of unemployed union members being 2·2 at the end of May compared with 2·3 in April, and 6·6 in May, 1895. Employment at steel works the kingdom over, including this district, continues to show a marked improvement as compared with a year ago. At 113 works included in returns received by the Board of Trade, the number of workpeople employed was 33,768 at the end of May, being 12·5 per cent. more than at the corresponding time last year, and ·3 per cent. more than at the end of April last. At the 89 puddling furnaces and rolling mills, however, from which returns were received, the number employed was less at the end of May than at the end of April, and also less than a year ago, the numbers being, for May, 16,946; for April, 17,695; and for May, 1895, 17,196. These statistics furnish further evidence of the extent to which steel is superseding iron.

The President of the Midland Counties Trades Federation at the annual conference of that body this week at Wolverhampton had some very sensible observations to offer anent the unreasonable outcry which it appears to be the fashion just now to make about foreign competition. He thinks we have very little cause for complaint, and that a comparison of our industrial and commercial position with that of some other nations may well give ground for thankfulness rather than envy. Our total imports from Germany amount to about £26,000,000 per annum, of which only £5,000,000 are manufactured goods, most of the remainder being food. On the other hand, we export to Germany goods to the value of £30,000,000, of which only £1,000,000 consists of food, the remaining £29,000,000 being manufactured goods, and especially machinery, metals, and hardware. While we take only £1,000,000 of iron and steel in manufactures from the United States, we send them £40,000,000 of manufactured goods. Taking all parts of the world together, while we purchase from abroad about £50,000,000 worth of manufactured goods, we export manufactures to the value of nearly £300,000,000, or six times the amount.

The brass workers in the Birmingham district have decided to give notice for an increase of 10 per cent. in wages, but it is hardly likely to be conceded by the employers without a struggle whilst competition continues so keen. The spring makers in the West Bromwich district have given a week's notice for a 12½ per cent. wages increase; and the lock makers of Wolverhampton have handed in notices for a 10 per cent. advance.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—A somewhat stronger tone if anything was noticeable with regard to prices both for pig and finished iron on the Manchester Iron Exchange on Tuesday. It is true there is a good deal of underselling amongst merchants and dealers, which is probably to be explained by the reasons I have referred to in previous notes, but makers are almost without exception firm at their quoted rates, the tendency being rather to harden in some directions. Lancashire makers of pig iron have no difficulty in effecting renewals of contracts with their customers at their full quotations of 46s. 6d., less 2½, for No. 3 foundry, delivered Manchester, and they are also getting better prices for forge qualities now that Lincolnshire makers, having sold freely at recent low rates, are not competing so keenly. In district brands some considerable sales of Lincolnshire forge have been made during the week at the advance of 6d. per ton, and makers in most cases have since put up their prices another 6d. per ton, the general quotation being now 41s. 6d., with foundry firm at 43s. as the minimum. Derbyshire foundry is also decidedly hardening, 46s. to 46s. 6d. net cash, delivered here, being now the average figures. As regards outside brands, makers' quotations are also, if anything, stronger, good foundry Middlesbrough not being obtainable under 45s. 10d. to 46s. 4d. net cash, delivered by rail Manchester, with Scotch iron averaging 46s. 3d. to 46s. 6d. for Eglinton, and 47s. to 47s. 6d. for Glengarnock, net prompt cash, delivered Lancashire ports, and about 2s. 3d. extra delivered Manchester Docks.

The finished iron trade shows a decided improvement, some of the local makers having booked pretty freely during the week, and at better prices. There is, consequently, an absence of the low selling reported recently, Lancashire crown bars not now being quoted under £5 10s., with North Staffordshire qualities £5 10s. to £5 15s. Sheets have been moving up, and are scarcely obtainable under £7 5s., whilst Association list rates for hoops are exceedingly firm at £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths, delivered Manchester district, and 2s. 6d. less for shipment.

No really noticeable move can be reported in the steel trade. Hematites are steady at late rates, averaging 57s. 6d. to 58s., less 2½. Manufactured material, however, remains low in price, considering the general active demand, local-made steel bars being still obtainable at under £6, whilst for boiler plates makers find it impracticable to get more than £6 5s., delivered in this district.

In the metal market, the upward movement in raw material, and the brisk demand for all descriptions of manufactured goods, has led to another advance in list rates of ½d. per lb. on copper tubes, ¼d. on brass tubes, and two separate advances of ¼d. per lb. on brass wire and yellow metal plates since the advance reported a fortnight ago. Brazed brass gas tubes are now quoted 7¾d.; brass wire, 6½d.; copper wire, 7¾d.; and rolled metals 6¼d. per lb. delivered Manchester district, with soft cold rolled copper sheets £68 per ton. This persistent upward move in prices does not appear to have checked business, as with locomotive builders and general engineers all very busy, and coppersmiths and brass founders well employed, a brisk inquiry for all descriptions of manufactured metal goods is reported generally.

Activity is fully maintained throughout the engineering trades, and I hear of further considerable orders being booked by locomotive builders in this district, whilst machine toolmakers have not been so busy for a considerable time past. Stationary engine builders, boilermakers, and the general branches of engineering all continue well engaged.

The monthly returns of the Amalgamated Society of Engineers are of much the same satisfactory character as those of other similar associations referred to last week. In the Manchester district there are now only ¾ per cent. on support, which represents a state of trade better than has been experienced for years past, and it is a long time since there was such a demand for certain classes of workmen as now exists. I may further mention that the Amalgamated Society of Engineers has added 3575 new members to its roll during the present year, and has now a total membership of 82,709. The Steam Engine Makers' Society has also only ¾ per cent. on donation—a slight decrease on the last report.

This exceptional briskness throughout the engineering industries is bringing the wages question to the front, and in addition to the movement on the part of sections of the workmen in one or two outside districts to which I have previously referred, the core makers in the Manchester district have now sent in notices for ao advance. There is not as yet anything in the way of a general move amongst the men for higher wages, and it remains to be seen whether this isolated action amongst comparatively small sections of the workmen is but a preliminary to further agitation should the present demands be conceded; but nothing definite has actually been done, as the notices have not yet expired, and are under the consideration of the Employers' Association.

An improved form of trap is being introduced by Mr. P. Mooney, Clarence-street, Manchester, for intercepting house drains from the sewer where a manhole is used. This trap has been specially designed for manholes when the line of the main house drain differs from the direction of the drain between the manhole and the sewer. Most local authorities insist upon an access arm from the chamber to the outlet side of the trap, and in the ordinary traps made in one piece bends have had to be made where the drain above the manhole is not in an exact straight line with the drain below it, or otherwise a second manhole is necessary. In the arrangement introduced by Mr. Mooney these complications are avoided by providing an adjustable piece, by means of which the inlet and the outlet can be placed in any required direction, and access is afforded to the lower side of the trap, so that the sewer side of the manhole can be thoroughly inspected, when required, in whatever direction the adjustable piece may be turned. The principle of this new trap has, I understand, been approved by many of the leading architects in the district.

The half-yearly meeting of the Manchester Association of Engineers was held on Saturday, Mr. Joseph Nasmith, the President, occupying the chair. The proceedings were chiefly of a formal character. Messrs. J. Matthews, of R. Johnson and Nephew, Bradford; J. A. Bennett, of the Lancashire and Yorkshire Railway Company, Horwich; W. Heap, of W. Rose and Co., Salford, were elected to ordinary membership. Messrs. J. Bolas, F. W. Reed, and F. Slade, members of Committee of Management; and Messrs. G. Kierman and J. Bartlam, auditors to the Association. I may add that by the courtesy of Mr. F. W. Webb, the society is paying a visit to the locomotive works of the London and North-Western Railway Company at Crewe on Thursday next.

Extreme quietude is reported in the coal trade, which is perhaps not more than might be expected, considering that the present period is the slackest season of the year. House fire qualities necessarily are only in the most limited request, and although many of the collieries are not running more than three and a-half to four days per week, a considerable portion of even this restricted output is going into stock. Quoted list rates are nominally unchanged, but for prompt clearance sales representatives of collieries are in most cases prepared to meet buyers with concessions, with the result that prices are weak and irregular. Common round coals are in fair demand for iron-making, steam and general manufacturing purposes, but continue plentiful and extremely low in prices, ordinary steam and forge coals being readily obtainable at 5s. 6d. to 6s. at the pit mouth. With regard to gas coals, many of the principal contracts are now under consideration, tenders having been sent in. Of course nothing definite as regards prices can as yet be reported, but so far as anything is known at present tenders seem generally to have been based on about 3d. under last year's rates, which would represent about 6s. 3d. at the pit for ordinary screened Wigan 4ft. gas coal, and 7s. for the better qualities of Arley gas coal. In engine fuel, the restricted production of slack, owing to the limited demand upon round coals, is necessarily causing some scarcity of supplies, but only in exceptional cases is any advance upon late rates being obtained. Last week there was some talk of advancing list rates 3d. per ton, but no general move in this direction has so far been attempted, and common slack can still be bought at 3s. to 3s. 6d., with better qualities ranging from 4s. and 4s. 6d. up to 5s. for some special sorts.

No improvement can be reported in the shipping trade, and ordinary steam coal does not average above 7s. per ton, delivered either at the ports on the Mersey or the Manchester Ship Canal.

The recent decision of the Railway and Canal Commissioners in favour of the railway companies with regard to the application by the Manchester and Northern Counties Federation of Coal Traders' Association, as to whether the new siding rent charges, which were put in force at the commencement of last year, of 6d. per ton per wagon after four days, exclusive of the day of arrival, were reasonable charges, has been received not only with disappointment, but with considerable surprise, by the merchants and dealers in this and other districts. The general opinion expressed is that the Federation were badly advised in bringing their application first against the Midland Railway Company, which stands in a very different position with regard to the question from the other important coal-carrying companies. The matter has been one of continued agitation and complaint amongst the coal traders for the past twelve months, and acting under the advice of the Federation, they have declined to pay what they consider the increased siding rent charges, with the result that these unpaid and disputed charges now amount to many thousands of pounds. The matter, however, is not to rest where it has been left by the Commissioners, and at a meeting of the Manchester and Northern Counties' Federation of Coal Traders' Associations, held on Thursday at the Manchester Coal Exchange, Mr. George Pearson, of Stalybridge, in the chair, at which there was a very large attendance, it was unanimously resolved that the railway companies be approached with reference to the matter; and that, failing any satisfactory outcome of the negotiations, the matter be proceeded with in such manner as may be decided by counsel. Every member receiving an application for siding rent is to forward it to the Association without delay; and a levy was made, the effect of which will be to raise £1000 for the immediate purposes of the Association.

Barrow.—The week's business in hematite pig iron has been on as large a scale as for some time past, and the business offering gives the assurance of the continuance of the present active market for a considerable time to come. The make of Bessemer iron practically represents the whole of the output, and the consumption by local makers of steel and others is a steady source of trade to smelters, who have large orders on hand, and are likely to be kept busy for the remainder of the year at any rate. Prices are steady at 47s. 5½d. net cash warrant sellers, 47s. 5d, buyers. Makers quote 48s. to 49s. for Mixed Bessemer Nos. net. f.o.b. Stocks have been increased during the week exactly 1000 tons. Thirty-nine furnaces are in blast as compared with twenty-nine in the corresponding week of last year.

Iron ore remains in good demand; the mines are busy, and repeat orders are readily given out. Prices remain unchanged at 10s. per ton for average qualities.

Steel makers report a very satisfactory trade. Orders for rails are held to a very large extent, both on home and foreign account, and the demand remains steady from all sources, while prices are firm. Shipbuilding material of all sorts is in good request, and it is evident the demand is likely to improve. Billets, hoops, and heavy steel castings are in active demand, and the market generally, in merchant qualities of steel, is gaining strength.

Shipbuilders and marine engineers are busy, but the need of new orders is asserting itself more and more every week. Builders hope to secure both Admiralty and commercial orders of some importance shortly, and in the meantime much activity is maintained in the work of completing the contracts in hand.

Coal finds an average market, but there is such a keen competition for orders that prices are kept at a very low point. In coke the trade doing is steady, and prices are well maintained. The supply obtained is chiefly from the Durham district, but a fair business is regularly done with the Burnley district.

Shipping returns from West Coast ports show an export of 6065 tons of pig iron and 13,791 tons of steel during last week, as compared with 7995 tons of pig iron and 6708 tons of steel in the corresponding week of last year, a decrease of 1930 tons of pig iron and an increase of 7083 tons of steel. The total shipments this year so far show 139,962 tons of pig iron and 214,399 tons of steel, as compared with 123,513 tons of pig iron and 163,902 tons of steel in the corresponding period of last year, an increase of 16,449 tons of pig iron and 50,497 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THERE is not much change to report in the working of the collieries in the South Yorkshire district. The stoppages at the collieries already noted still continue, and trouble is expected from several other pits in this part of the coalfield. The present bright warm weather is having an adverse effect on the consumption of house coal. London is taking but an average supply, and values continue low, owing to the keen competition of seaborne fuel. On account of the decrease in the consumption of gas coal only a moderate tonnage is being forwarded to the eastern counties. Merchants are just able to keep up prices, in spite of the fact that unscreened coal and slack can be obtained at the thick seam pits at 5s. per ton. Silkstone, which is only moderately produced, is quoted at 8s. to 8s. 3d. per ton for the best, and 7s. to 7s. 6d. for secondary qualities. Barnsley softs realise 7s. to 7s. 3d., and the best thin seam coal only fetches 6s. per ton at the pits. The condition of the steam coal trade is fairly satisfactory. The output, however, continues largely in excess of the demand, so that an increase in prices is entirely out of the question. A heavy weight of coal is still being sent to Hull. A good tonnage of the best qualities of steam coal is finding its way to Grimsby. The railway companies are taking a large quantity of coal on contract account. The Lancashire and Yorkshire Railway Company has just placed contracts for the supply of locomotive fuel. It is understood that the contract price is under that of the Midland, 7s. per ton. Best Barnsley steam coal commands 7s. to 7s. 6d.; Parkgate, 6s. 3d. to 6s. 6d. Gas coal continues to be freely inquired after. Good slack is at 3s. to 3s. 3d., ordinary pit realises 2s. 3d. to 2s. 6d., and smudge, 1s. 6d. per ton in quantities at the pits. The coke trade continues very satisfactory. The output is large, and a good tonnage is being forwarded to North Lincoln, as well as to Derbyshire and Northamptonshire, at prices ranging from 8s. 6d. to 11s. per ton.

Good reports are still coming in from the heavy industries. Business is very brisk in almost every department. Rather a falling-off is exhibited in the railway material branches. There are some very satisfactory orders yet to work off; and it is expected that before these are completed orders will come in for wheels, tires, axles, and similar goods. An improved demand is reported for both Bessemer and Siemens-Martin steels, as well as for crucible steel of the best brands. The rolling mills, tilts, and forges are well employed. Quotations for raw and finished material run as follows:—Bessemer billets, £5 12s. 6d. to £6; hematites, 55s. to 57s. 6d. per ton, according to brand, delivered in Sheffield; bar iron, firm at £5 10s. at makers' works. For Swedish iron and steel the enormous demand for cycle purposes formerly noted is fully sustained. Great Britain, France, Germany, and the United States are the principal customers. The contract rates range from £12 to £16 per ton f.o.b. For the best brands, which come from the Dannemora district, and are made both on the Bessemer and Siemens process, £16 is easily obtained, the Germans being large buyers of the higher-priced brands. Many thousands of tons have also recently been purchased by Birmingham firms at about £15 per ton; while Sheffield manufacturers have been buying very heavily in all the Swedish iron and steel centres. For the commoner qualities, chiefly rolled for rails and ship-plates, about £7 per ton is realised; in 3in. billets the price is about £7 per ton.

The lighter trades are in a satisfactory condition. The demand for silver, electro-plates, and similar metals has been increasing ever since Easter, although the weight of silver rolled is rather less than for the corresponding period of last year. Several of the larger firms have never been so busy as they are at the present time. Better advices are being received from the leading continental markets, where a more animated business is pretty general in tools and general hardware goods, but orders are not pressing for immediate delivery. The business in table cutlery is in one or two directions abnormally heavy, and there is a good run on the pen and pocket branches. The best part of the trade doing, however, is in case goods. Reports as to the state of the Russian, Australian, and United States markets are very encouraging. It is confidently expected that the full trade with the more important foreign countries will be much more important than for the first six months of the year. Sheffield manufacturers, however, are not very sanguine about American business. A large American manufacturer, who makes goods in Sheffield for his transatlantic stores, does not anticipate that the United States demand for the higher classes of cutlery, which has been steadily maintained since the trades in the secondary grades was taken by Germany, or self-supplied in the States. He does not expect that any immediate results of importance will follow the almost inevitable election of Mr. McKinley. What the country wants, he says, is a quiet time of commercial confidence, and even a higher tariff, if it put an end to the unrest and distressing fluctuations of values, would be better than the present situation, when a man goes to bed at night and may rise next morning to find himself one-half poorer than he was when he laid down the previous evening.

In the file trade customers have been advised that owing to the advance of 10 per cent. in wages, discounts are shortened by 2½ per cent. This has given our rivals of France, Germany, and America another opportunity to push their low-priced wares, and it is feared that the result will be more than a temporary displacement of Sheffield-made rasps and files.

Mr. Amos Joseph Acaster, engineer of the Princess Works, Shoreham-street, died very suddenly on the 16th inst. While engaged at his establishment the previous Thursday, Mr. Acaster was much affected by the heat, and drank cold water freely to quench his thirst. Shortly afterwards he was taken ill, but declined medical aid. On Sunday he was very much better, but early on Tuesday morning had a relapse, which terminated fatally about seven o'clock. Mr. Acaster, whose forefathers were early in the local engineering trades, was the inventor of the Acaster patent rail joint and other contrivances of utility and interest. By skill and industry he had greatly extended his Princess Works, which were in a prosperous condition. He was fifty-six years of age, and leaves a widow and three sons.

The Master Cutler, Mr. H. H. Andrew, of the Toledo Steel Works, entertained a number of friends at Endcliffe Hall last Saturday night, in celebration of the coming of age of his elder daughter, who is the Mistress Cutler of Sheffield. Miss Andrew is the youngest lady who has ever occupied that position, and the reaching of her majority during her father's year of office is also unique. The event was very pleasantly referred to by Mr. Joseph Mellowes and Mr. H. W. Pawson at the supper, and "The Good Health of Miss Andrew" was heartily honoured. Mr. Andrew feelingly responded. Mr. Robert Colver—Messrs. Jonas and Colver, Continental Works—in exceptionally felicitous terms, proposed "The Health of Mr. Andrew and Miss Maud Andrew," which was also warmly honoured, and acknowledged by Mr. Andrew in happy terms. The term of office nominally extends to the first Thursday in September, when the new master is installed; practically it expires in the second week of August, when the Cutlers' Company meet to elect their new head. Mr. Andrew's term will be remembered as one of the most memorable in the Company's annals, alike for the brilliance of his hospitalities, the attention he has given to the work of the ancient corporation, and the uniform courtesy and modest efficiency with which he has discharged all the duties appertaining to the office, which he will leave with the warmest good wishes, not merely of his colleagues in the company, but of the whole community. In Sheffield the Mayor and the Master Cutler are much associated in local work, and the civic chair during his year has been occupied by the Duke of Norfolk. Between the two, collaboration in public and other appointments has been mutually pleasant, as well as satisfactory in its results to the city.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

ON the whole the course of trade in this district is satisfactory, prices generally keep firm, and as prospects are favourable buyers are much more ready to purchase than producers are to sell, particularly where iron for forward delivery is concerned. A considerably better trade is being done than is usual in June, not only in pig iron, but also in finished iron and steel, as well as in the smaller industries, not one of which can be described as really dull. The tendency in prices is upwards, as now that producers are so well supplied with orders competition has become less keen than has been known for several years past, and a better chance of realising higher prices is afforded. The production of pig iron in the North of England is the largest ever recorded in the history of that trade, but at the same time the deliveries have never been so heavy, especially on shipping account, and it is believed that makers will have to draw upon their stocks. The extent of the deliveries at this time of the year, when there is usually a quiet time, is unexpected, and affords excellent evidence of the soundness of the improvement which is taking place in trade. If business is so well maintained in the summer months, it may be inferred that there are very encouraging prospects for the autumn. Shipments of pig iron have not fallen off during this month as was expected; on the contrary, though they have not this week been on as large a scale as during the first ten days of the month, they are very good, and the total for the month so far has been the best on record. Up to Wednesday night the quantity was 67,336 tons, as compared with 54,514 tons last month, 60,263 tons in April, and 64,071 tons in June, 1895, all to 17th. With such an export as that, and with large local deliveries also, better prices ought to be realised, and they would be realised if there were not such an enormous make. Producers have only themselves to blame for the comparatively poor prices they obtain —they increase the output too rapidly, and carry on too keen a competition. If they would regulate the make, and keep it a little below the requirements instead of a little above, as is now mostly the custom, they would benefit not only themselves, but also makers in other districts, whose prices have to be kept down in order to enable them to compete with cheap Cleveland iron. It is satisfactory to see that the quantity of Cleveland pig iron sent into the public stores is very small, but with such deliveries there should be a decrease rather than an increase of stocks in the warrant stores. Connal's on Wednesday night held 199,228 tons of Cleveland iron, an increase for the month of 778 tons only.

The general price of No. 3 Cleveland G.M.B. pig iron has this week been steady at 37s. 6d. per ton for prompt f.o.b. delivery, and nothing less is reported to have been taken by makers, but some of the second hands have sold at a smaller figure. For deliveries to be made over July and August, 37s. 9d. has been accepted, but producers generally hold off for more. Cleveland warrants have this week shown more strength than other descriptions of warrants, and there has been the unusual circumstance of Cleveland warrants rising in value when the others were falling. The market for Cleveland warrants is influenced by the good outlook, and by the smallness of the additions to the stocks in the public stores. Buyers of Cleveland warrants have mostly offered 37s. 6d. cash for them this week, but on Wednesday they would only pay 37s. 4d. The lower qualities of Cleveland pig are more readily obtainable, but the prices are maintained, No. 4 foundry at 36s. 9d., and grey forge at 36s. 3d.

A number of the Cleveland pig iron makers are now using the rich magnetic Gellivara Swedish ore as an addition to the Cleveland store in making ordinary foundry and forge pig iron. They find this ore works profitably in the blast furnace, and improves the quality of the pig iron produced.

Cleveland hematite pig iron is believed to be in larger supply than demand, and the price is hardly so strong as is that for ordinary Cleveland iron, notwithstanding that ore is dearer. The opinion is that producers are adding materially to their stocks, but that can be little more than conjecture, as no statistics of stocks are collected, as some of the makers refuse to give the information, a refusal which hardly can be condemned, as it is not always advisable to admit the public into the position of business. Mixed numbers of East Coast hematite pig iron can be bought at 45s. 6d. per ton for prompt delivery, but the general figure is 45s. 9d., and several of the leading firms hold out for 46s. Rubio ore maintains its increased value, and 12s. 9d. per ton, delivered at Tees wharves, has to be paid for 50 per cent. ore, especially as rates of freight are advancing, Bilbao-Middlesbrough being now 5s. 4½d.; Bilbao-Stockton, 5s. 6d.; Elba-Tyne, 8s.; Garrucha-Tyne, 8s. 1½d.; and Bilbao-Jarrow, 5s. 1½d.

The leaders of the Cleveland blast furnacemen, in spite of all the arguments used by the employers as to the inconvenience and loss caused by a day's stoppage of the furnaces, have determined to hold their demonstration at Middlesbrough on Friday, August 14th. The cost of the stoppage to the masters alone is calculated by them at £5000. Not only does production cease for the day, but there are the after-effects to be considered, as for some time after the stoppage the quality of the iron produced is inferior. It is essential that a furnace, to give good results, should be worked regularly. The blast furnacemen evidently want to be in the fashion—the ironstone miners and colliers have their annual demonstrations—and though the blast furnaces are worked under different conditions, this is not taken into consideration by the men.

Most of the finished iron and steel manufacturers give good accounts of their business; they are nearly all well employed, and in some cases have difficulty in supplying as promptly as is desired the needs of their customers. The heat of this week has come rather inopportunely for manufacturers, as it has necessitated a curtailment of their production, for the puddlers and some of the millmen were unable to pursue their occupation during the greater part of the day. The steel rail makers are well employed, and large shipments of railway material have this week been made to Algoa Bay, Egypt, India, &c., from the Tees, while other large cargoes are being loaded. The nominal price of heavy steel rails is £4 10s. per ton net at works. A good demand has sprung up for girder, sheet, tee, and channel iron, and the tendency in prices is upwards.

Scarcely anything is being done in steel sleepers now, but an unusual shipment from the Tees is reported this week—wooden sleepers; heretofore only metal sleepers have been exported from the river, but they are getting out of favour in some quarters. Steel ship plates are in fair request, but the demand runs more on girder and boiler plates than it did. Steel ship plates are firm at £5; steel boiler plates at £6; steel girder plates at £5 5s.; steel ship angles at £4 17s. 6d.; iron ship plates, £4 17s. 6d.; iron ship angles, £4 15s., all less 2½ per cent. and f.o.b. Sheets are in excellent request, especially galvanised sheets. Cast iron pipes and railway chairs are in improving demand, and almost all the works producing them are well employed. Bridge builders keep their establishments in regular operation, and engineers are as a rule well off, more especially the locomotive and marine engineers.

The death took place a few days ago of Mr. William Bosher, who for the last twenty-two years has been chief cashier of Messrs. Bolckow, Vaughan, and Co. He has spent his whole business life with the firm, having entered their office at the age of fourteen years. He was nearly fifty years old at the time of his death. The death also is reported of Mr. J. Tait, who for the last twenty years has been manager of the Raisby Hill Limestone Quarries, the produce of which is much esteemed in the manufacture of pig iron in Cleveland. Mr. R. E. Robinson, son of Mr. Robert Robinson, chief manager of Messrs. Bolckow, Vaughan, and Co.'s collieries, met with a sad death at the Hazelrigg pit in Northumberland. Deceased was a mining student, aged twenty-three years, and had latterly acted as overman under his father at the Auckland Park Colliery. On the day of his death he visited South Northumberland for the purpose of inspecting the shaft sinking operations at Cramlington and Hazelrigg pits. While inspecting the shaft at the latter pit he descended in the "kibble" to a depth of sixty-four fathoms, and there got upon the "cradle." There the master sinker explained to the deceased the work of putting in the guides for the cages. While looking up to inspect the guides he appears to have stepped back and fallen a depth of sixty fathoms.

The demand for steam coal is active, and work is very brisk at the Northumberland collieries. Part of the activity is due to the approach of the holidays, which are always observed at the pits in the neighbourhood of the Tyne during Newcastle race week. There is also a more than usually brisk demand for coal for the Baltic ports, as merchants are taking advantage of the low rates of freight that are ruling. Best Northumberland steam coals are at 8s. 6d. per ton f.o.b. Gas coals are in slack request, but that is usual at this time of the year, which is always a quiet time. Coke is now in better supply than demand, and some of the manufacturers are putting it into stock. The situation is thus quite different from what it has been for months, and prices are weaker. Average coke delivered at Teeside furnaces can now be bought at 13s. 6d. per ton. Messrs. Cook and Sons, Washington, have completed the construction of an improved coal screening apparatus, which is to be sent out to the Great Eastern Coal Company's mines in South Africa.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE has been a quieter feeling in the Glasgow pig iron market this week, and only a moderate business has been done in warrants. The active state of the manufacturing branches helps to keep prices fairly steady. Were it not for this activity it would be a comparatively easy matter at present for operators to depress prices, seeing that stocks of pig iron are on the increase. Business in the open market has been mainly confined to Scotch warrants, which have sold from 46s. 8d. to 46s. 9d. cash, and 46s. 9d. to 46s. 10d. one month. Cleveland warrants have met with very little inquiry. They are quoted 37s. 5d. to 37s. 6d. cash. There has been very little doing in hematite warrants, the price of Cumberland being steady about 47s. 5d. to 47s. 6d. cash.

The number of furnaces producing ordinary pig iron has been reduced by one, and there are now 38 making ordinary, 39 hematite, and three basic iron, the total of 80 comparing with 75 at this time last year. Large quantities of Spanish ore are being imported, and the consumption of it at the ironworks is perhaps greater than at any former time. The rate of freight for this ore from Bilbao to Glasgow is 5s. 6d. per ton. The price quoted for Scotch-made hematite pigs, delivered on railway trucks at the steel works, is 50s. per ton.

The makers of Scotch pig iron have, in a number of instances, reduced their prices 6d. per ton, and the quotations are now as follow:—Govan, Monkland, and Carnbroe, f.o.b. at Glasgow, Nos. 1, 47s. 6d., Nos. 3, 46s.; Clyde, No. 1, 49s. 6d.; No. 3, 46s. 6d.; Gartsherrie, Summerlee, and Calder, Nos. 1, 50s.; Nos. 3, 47s. 9d.; Coltness, No. 1, 52s. 6d.; No. 3, 48s.; Glengarnock, at Ardrossan, No. 1, 49s. 6d.; No. 3, 45s. 6d.; Eglinton, No. 1, 47s.; No. 3, 45s.; Dalmellington, at Ayr, No. 1, 46s. 6d.; No. 3, 44s. 6d.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 48s. 6d.; Shotts, at Leith, No. 1, 52s.; No. 3, 48s. 6d.

The stocks of pig iron in the Glasgow warrant stores continue to increase, and the addition in the past week amounts to about 1660 tons. The total stocks show since the beginning of the year an increase of 16,000 tons over those for the corresponding period of last year.

The foreign demand for Scotch pigs is very backward, and the shipments during the past week are considerably below the average, amounting to only 4011 tons, compared with 6816 in the corresponding week of last year. No pig iron was despatched either to the United States, Canada, or South America, but there was sent to India, 125 tons; Australia, 340; France, 40; Italy, 330; Germany, 1055; Russia, 280; Holland, 115; Belgium, 15; Spain and Portugal, 155; China and Japan, 13; other countries, 270; the coastwise shipments being 1273 tons, against 5638 in the same week of 1895.

The market for finished iron is steady as regards prices, and the quantity of material going into consumption is comparatively large. The steel works continue very busy.

Messrs. Blackwood and Gordon, of Port Glasgow, have contracted to build a screw steamer of 1600 tons gross, with engines of 900-horse power, for Messrs. Alex. A. Laird and Co., of Glasgow, for their cross-Channel traffic between English, Scotch, and Irish ports.

There has been rather more doing in the shipping department of the coal trade, and the total clearances from Scottish ports have been 161,297 tons, compared with 152,779 in the preceding week, and 176,215 in corresponding week last year. The market, however, continues very slack owing to the large supplies. Furnace coal and dross are in brisk request, and there is a good demand for the better qualities of ell coal. The turnover in splint and main is by no means small, but owing to the large output from the collieries prices are depressed. Main coal is quoted f.o.b. at Glasgow, 5s. 9d.; splint, 6s. 3d. to 6s. 6d.; ell, 6s. 3d. to 6s. 9d,; steam, 7s. 6d. per ton. The warm weather has been curtailing to a great extent the demand for household coals.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

I AM gratified in being enabled to report a return to active and hopeful conditions in the coal trade. The total exports from the Cardiff ports last week totalled 355,000 tons. Both Newport and Swansea coal shipments last week indicated improvement, and the buoyancy of the steam coal trade appeared even to tell favourably upon house coal business, which, notwithstanding the hot weather, showed signs of a better character than of late. One good result of the Charter agitation was that prices on Saturday last advanced 3d. per ton.

Mid-week prices, Cardiff, were as follows:—Best steam coal, 10s. 3d. to 10s. 9d.; special seconds, 9s. 9d. to 10s.; seconds, 9s. 3d. to 9s. 6d.; drys, 8s. 9d. to 9s. 3d.; best Monmouthshire, 8s. 6d. to 8s. 9d.; seconds, 8s. to 8s. 3d.; special smalls, 5s. to 5s. 3d.; best quality, 4s. 6d. to 4s. 9d.; seconds, 4s. to 4s. 3d.; drys, 3s. 9d. to 4s. Cardiff, cash thirty days, less 2½. Swansea figures this week are:—Best anthracite, 11s. to 11s. 3d.; seconds quality, 9s. to 10s.; ordinary large, 8s. to 8s. 9d.; rubbly culm, 4s. to 4s. 6d.; steam, 9s. to 10s.; bunkers, 7s. 9d. to 9s.; second-class steam, 8s. 3d. to 9s.

House coal prices at Cardiff are, best, 9s. 9d. to 10s. 3d.; No. 3, Rhondda, 9s. 6d. to 9s. 9d.; brush, 7s. 9d. to 8s.; small, 6s. to 6s. 3d.; No. 2 Rhondda, 7s. to 7s. 3d.

Coke prices are well maintained at last week's figures, namely, 13s. to 19s. 6d., according to quality. Patent fuel, 10s. 3d. to 10s. 6d.; pitwood, 15s. 9d., all Cardiff.

Iron ore prices are firm, and large cargoes continue to come in for the leading ironmasters. Ebbw Vale figures well. Prices, Cardiff, 10s. 9d. to 12s. according to quality.

At a meeting of the Monmouthshire and South Wales Coalowners' Association, held on Tuesday at Cardiff, several important matters were brought forward and discussed. One was the coal charter party, and the movement to oppose the introduction of the new principle of payment of wharfage by the coalowners was commended. It was decided also to support the Bill of the Home Secretary for the amendment of the Mines Regulation Act. With regard to the defences of the Channel, it was contended that the measures adopted for protection were inadequate, considering that the colliery owners of Wales have an output of 35 million tons annually.

The Windsor Dock Bill is now passing its ordeal, and a strong array of counsel is piloting or opposing.

Sir William T. Lewis, this week in thanking a deputation from Hirwain for a valuable testimonial to himself and Lady Lewis, on the occasion of his baronetcy, gave briefly, in reply to the speaker, the history of the sliding scale, which has admittedly done more excellent service to the coal trade, coalowners, and colliers than any other institution or arrangement. The project was first mentioned by Sir William to Sir H. H. Vivian, afterwards Lord Swansea, and the idea having been discussed thoroughly, Sir William applied himself to the matter, matured it, and after great research and much comparison of rates of wages in various districts, brought it to a successful issue. Sir William admitted that he was more proud of the sliding scale than of any other success of his life.

I am reminded of the scale by seeing the results of another of his successful undertakings, the Miners' Provident Fund. The ordinary quarterly meeting was held at Cardiff on Saturday, and the first resolution carried was one of earnest sympathy with its chairman, Sir W. T. Lewis, and regret for his illness, coupled with a strong expression of hope that he would soon be at the helm again. The secretary's report showed that the society is doing excellent work. £13,062 had been paid in during the quarter by workmen, £2970 by employers. The sum of £1025 has been paid for funeral expenses, £2822 to widows, £2520 to children, and £7724 to disabled members. During the quarter there had been 38 fatal accidents, by which 95 members had lost their lives, and there were on the funds at the end of the quarter 866 widows and 1512 children.

The iron and steel trades are fairly good. On 'Change, Swansea, it was reported mid-week that the pig iron market remained practically unaltered, easier if anything in some grades, but a fair demand for home consumption and for foreign supply. Prices indicate no change, except in steel rails, which are offered from £4 7s. up, heavy sections, as low a rate as can be expected; light from £5 10s. Iron and steel plates, Bessemer and Siemens bars, are unchanged. Tin-plates also continue the same: Bessemer from 9s. 3d. to 9s. 4½d., and Siemens coke finish, 9s. 6d. to 10s.; ternes, 16s. 6d. to 21s. 6d.; best charcoal, 13s. to 13s. 3d. Trade is much the same. Fortunately no more mills have been started.

Cyfarthfa continues moderately busy in rails and bars, and Dowlais maintains a good front. Ebbw Vale keeps a more brisk appearance, and if this should continue a more favourable report than the last may be anticipated. It is stated that one of the drawbacks there is a scarcity of men, forty additional workmen being required in the Bessemer department alone. A good sign also comes from Briton Ferry, where it is intended, in connection with the Albion Works, to erect another furnace forthwith. A good average make of pig at the Briton Ferry Works is going on, and of steel bar at the Briton Ferry Steel Works.

The improvement in the tin-plate trade has reacted favourably upon the steel works, and the demand for bars is sometimes sharper than can be met. Last week the shipments of plates amounted to 59,500 boxes; quantity received from works, 46,628, still further reducing stock. Cardiff and Newport next week are to be visited by the North-east Coast Institution of Engineers and Shipbuilders, and, judging from the programme, both places will do their best in the exhibition of the leading features of industries in Monmouthshire and South Wales.

Colliers are getting reckless again. Two in the Rhondda were fined £2 or a month for unramming a shot at one of the Ocean Collieries. It was a wonder both were not blown to pieces.

The patent fuel trade at Swansea is getting into its old groove, no less than 11,000 tons having been shipped last week, and leading makers have orders for three months in hand. Swansea reports a boom on the copper market, and are advancing £2. Block tin is also advancing, and is 30s. better than last week. Present prices: Copper, £50 to £50 2s. 6d; tin, £61 13s. 9d. to £61 15s.

The dispute at Abby Colliery, Rhondda, affecting 300 men, has been settled. The Ebbw Vale directors' report indicates a good deal of effort, and consequently expenditure in the improvement of the steel works and development of the coalfield; but though no dividend is announced, prospects are decidedly better.

The opposition against the Cambrian Railway Bill having been withdrawn, it has been referred to the consideration of the unopposed committee in the House. The further arrangements of the Llandudno Eisteddfod, the Prince of Wales' reception at Aberystwith, and the meeting of the Cambrian Archæological Association upon the occasion of its jubilee, promise well for the Cambrian and Brecon lines.

I see that the Bute Docks and Rhymney Amalgamation Bill has passed its second reading in the House of Commons.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

REPORTS concerning the iron and steel trade remain favourable. There is plenty of work available for makers and manufacturers, and orders are constantly been placed for a variety of material. Prices tend upwards.

In Silesia the iron market continues in a very good position Considerable sales are reported in pig iron, prices being extremely firm. For good forge quality No. 1 M. 60 p.t. is quoted, foundry pig standing on M. 57·25 p.t. at works.

In the malleable iron trade the great activity so frequently reported before has been well maintained all through last week. Foreign demand increases, plates, railway requirements, and the various kinds of small manufactured goods meeting with particularly brisk request.

Very little change has taken place in the iron and steel trades of Austria-Hungary since last week, nor is there any likelihood of much alteration for the present. All round a satisfactory employment is reported. Girders, heavy plates, and structural material in general continue brisk of sale, and there have also been numerous inquiries received upon the week. Galvanised sheets met with an advance of 50 kr. p. 100 kgr. Several other branches, among them the cycle industry, which is specially brisk, are now experiencing a period of improved activity. Some years ago there were only a few large cycle manufactories in Austria, but at date their number has increased to twenty, total production being estimated at 25.000 to 30,000 cycles, worth four to five million florins. The largest of these establishments is that belonging to the Austrian Arms Factory in Styr, which sold about 8000 cycles last year. In 1895 there were exported from Austria 1811 cycles, against 658 in 1894. Import in the same year amounted to 2309, against 3646 in 1894, 1043 coming from England and 1030 from Germany.

The French iron business was comparatively quiet through the greater part of last week, only few orders having been received at the iron works. An alteration in prices cannot be reported to have taken place, bars still fetching 150 to 155f. p.t., while girders are quoted 160f. p.t.

During the week that is now past the different departments of the Belgian iron industry have been exhibiting considerable animation, and there is a healthy tone perceptible in all branches. A specially gratifying fact is that merchants report a better inquiry from abroad, and as foreign demand has been rather weak for some time, an improvement in this direction is naturally hailed with much satisfaction. Bars No. 2 for export are at present offered at 125f. to 127·50f. p.t.; No. 3, 130f. p.t.; iron plates, No. 2, 145f. p.t.; steel plates, 150f. p.t. There has been much life stirring in the steel rail business just lately, and many fair orders have been secured. At a recent tendering for 4000 t. of steel rails for the Portuguese State Railways, the steel works Angleur got the contract, offering lowest at 119f.; the Bochum Steel Works asked 126·50f.; Krupp, 130f.; and Gute Hoffnungshütte, in Oberhausen, 141·25f.

In the Rhenish-Westphalian district business transactions on the iron market continue very satisfactory. In most instances the prices realised may be considered remunerative, and prospects for further advances are decidedly favourable. The business done in the different sorts of pig iron is good, and makers have plenty of orders to engage their attention for some time. Indeed they are, as a rule, booked forward for fully six to seven months ahead. In the malleable iron trade a fair weight of business continues to be reported, and prices for bars are more firm than ever, but leave rather a small profit on the whole. It is, therefore, very likely that a further advance will be agreed upon at the meeting of the Rolling Mill Convention, which is to take place after the 15th inst. The girder trade is in an active position. Plates are also very brisk of sale; particularly those for boilermaking purposes are in very good call. The same holds for sheets. The wire and rivet trade remains without material change, but all through last week a fair demand has been coming in. Pretty many orders have of late been received at the tube mills; stocks show a slight falling off, and the belief is that the tube business will be much livelier this year than last. Quotations for cast iron tubes, which reached the lowest point in March, but have since then been slightly raised, are still exceedingly low, and leave next to no profit.

The total output of the Saar collieries is reported to have been for May of present year 592,925 t., consumption amounting to 595,785 t. During the corresponding month last year 539,690 t. were produced, while 559,500 t. were sold.

According to the annual statistical report of the railways in Germany which has just been published for 1894-95, length of the railway lines was 44,167 kiloms.; length of rails, 79,495 kiloms.; total weight of rails amounting to 5,047,530 t. The number of locomotives is 15,839, while there are 36,354 passenger cars, 319,578 freight cars, and 318,749 load wagons. There were consumed 4,831,181 t. pit coal, and 68,098 t. coke. The number of passengers was 542,745,878, earnings being M. 39,219,812. Tonnage of goods traffic was 22,066,956,833, earnings amounting to M. 963,450,723. Revenue was M. 1,410,262,052; expenditure, M. 860,069,152, surplus amounting to M. 550,192,900. The number of employés and labourers was, on an average, 363,604 per annum, while the wages paid were M. 457,425,597.

Value of German imports is officially stated to have been for 1895, M. 4,246,111,000, against M. 4,285,533,000 in the previous year, which shows a decrease of M. 39,422,000.

Value of export was M.3,424,275,000 against M. 3,051,480,000 in the year before, which is equal to an increase of M. 372,795,000.

During the year 1895 there were produced in Russia—including Siberia and Finland—88¾ million pud pig iron, 28⅓ million pud malleable iron, and 35 million pud steel. Import in iron and steel shows the following figures for 1895:—Pig iron, 8⅓ million pud; raw cast iron and steel, 18⅓ million pud; hardware and tools, 2 1/12 million pud; machines and apparatuses, 6 million pud. This shows that Russia, in spite of an increasing inland production, had to buy 47⅔ million pud from foreign countries in order to cover the continually improving home demand. Indeed, the tendency of the Russian iron market is getting firmer from week to week, and in nearly all departments the prices move in an upward direction.

It has been stated that in 1894 import of foreign ore to France has increased 8000 t.; from Algiers a comparatively small quantity is imported, chief supplies coming from Germany and Luxemburg. Spanish ore is principally consumed in the Department Pas de Calais, Landes et Loire-Inférieure. There came from Algiers, 16,000 t.; from Germany and Luxemburg, 162,000 t.; from Spain, 396,000 t.; Belgium, 46,000 t.; Greece, 8000 t.; other countries, 10,000 t.; together 1,638,000 t., or 8000 t. more than in the previous year. French exports in ore amounted to 248,000 t., or 54,000 t. less than in 1893. To Belgium 110,000 t. were sent; 55,000 t. went to Holland and 48,000 t. to Germany. Exports in ore from Algiers were, for 1894: 308,000 t., having increased 33,000 t. against 1893. Of the above 308,000 t., England received no less than 172,000 t., Low Countries, 103,000 t.; France, 16,000 t.; Belgium, 12,000 t.; Austria and other countries, 5000 t. In France were consumed 3,524,000 t. inland ore and 1,638,000 t. foreign ore, together 5,162,000 t., total consumption of ore having increased 317,000 t. against 1893. Output of pig iron in France increased during the same period 67,000 t

THE PATENT JOURNAL.

12,217. Iron Hurdles and Fences, S. J. Narracott, Torquay.
12,218. Handle Bars of Cycles, W. E. Partridge, Birmingham.
12,219. Lenses, P. Rudolph, London.
12,220. Manufacture of Gun Cotton, J. W. Swan, London.
12,221. Conveying Bread Doughs, R. K. Balcarras, London.
12,222. Brushes, W. C. Rider, London.
12,223. Mud Guards for Cycles, &c., C. Warren, London.
12,224. Tobacco Pipes, P. Marimian, London.
12,225. Brake for Wheeled Vehicles, A. Ross, London.
12,226. Saddle-bows, C. Egholm, London.
12,227. Secondary Voltaic Batteries, L. Epstein, London.
12,228. Lubricant, F. J. Reinisch and H. Lesser, London.
12,229. Stall Flooring, M. Logan, London.
12,230. Clasp, R. W. Barker.—(*E. N. Gaillard, United States.*)
12,231. Cigar and Cigarette Holders, T. H. Short, London.
12,232. Driving Gear, B. Ljungstrom London.
12,233. Cycles, J. C. Sawer, Brighton.
12,234. Single-trigger Double-barrel Guns, G. Bouckley, jun., London.
12,235. Capsuled Bottles and Vessels, L. Lowndes, London.
12,236. Engines, H. Richardson, Birmingham.
12,237. Manufacture of Armour Plates, J. W. Spencer, London.
12,238. Puzzle Box, J. A. Mannell, London.
12,239. Chain Wheels, C. H. Guest, London.
12,240. Construction of Cigarette Cases, F. Horton, London.
12,241. Apparatus for Killing Fishes, H. Buchan, London.
12,242. Frames of Cycles, J. E. Webb and M. F. Purcell, London.
12,243. Cycle, &c., J. E. Webb and M. F. Purcell, London.
12,244. Electrical Lighting Apparatus, E. Oldenburg, London.
12,245. Separation of Gases, W. P. Thompson, Liverpool.
12,246. Shafts of Vehicles, J. K. Pilkington and H. Tate, Liverpool.
12,247. Saddles for Cycles, &c., S. D. S. Ross, London.
12,248. Automatic Switches, W. J. Davy, London.
12,249. Electric Arc Lamps, W. J. Davy, London.
12,250. Secondary Galvanic Batteries, C. Marschner, London.
12,251. Self-sustaining Pulley Blocks, R. E. B. Crompton and E. A. N. Pochin, London.
12,252. Wheels for Velocipedes, C. A. and W. H. Chapman, London.
12,253. Water Chambers for Water-tube Boilers, H. H. Lake.—(*J. and A. Jensen and Dahl, Norway.*)
12,254. Protecting Animals from Insects, A. J. Boult.—(*C. L. Durand, France.*)
12,255. Precipitation of Precious Metals, M. B. Zerener, London.
12,256. Bending Ship Frames, M. H. C. and R. E. C. Shann, London.
12,257. Socks for Boots and Shoes, H. A. Thornton, London.
12,258. Pressure-controlling Apparatus, A. Hora and V. Wenzel, London.
12,259. Dynamo-electric Machines, V. A. Fynn, London.
12,260. Preventing the Falling of Draught Horses, D. M. Lindwall, London.
12,261. Shuttle-threaders, S. A. Brodeur, London.
12,262. Perfume Cushion, H. H. Lake.—(*O. Lepraux, France.*)
12,263. Operating Steering Wheels, D. S. Christison, London.
12,264. Chain Gearing for Cycles, &c., S. Bennett, London.
12,265. Spinning Top, W. H. Hawkings, London.
12,266. Electricity Meters, W. M. Mordey, London.
12,267. Machine Tools for Drilling, &c., R. G. Brooke, London.
12,268. Pneumatic Tires for Cycle Wheels, H. Faulkner, London.
12,269. Fabric for Pneumatic Tires, H. Heaton, jun., London.
12,270. Attaching Valves for Pneumatic Tires, H. Heaton, jun., London.
12,271. Separating Light and Heavy Substances, H. Seck, London.
12,272. Automatically Encashing News-deliverer, F. Klein, Cologne.
12,273. Car-coupling, F. Grün, Cologne.

5th June, 1896.

12,274. Internal Combustion Motors, J. W. Hunter, London.
12,275. Self-lighting and Part Driving of Bicycles by Electricity, M. Twomey.—(*M. Twomey*, ——.)
12,276. Supply of Oil to Vapouriser, W. Henderson, Tyrone.
12,277. Self-acting Damper for Hot-water Apparatus, R. Heaton, Birmingham.
12,278. Securing Bedstead Knobs, &c., J. Caulton, Derby.
12,279. Pedals for Velocipedes, J. Greenall and A. Jones, Leeds.
12,280. Securing the End Loops of Ropes, M. S. Meldrum and E. Clarke, Newcastle-on-Tyne.
12,281. Additions to Small-arms, A. Tunstall, Birmingham.
12,282. Mole Traps, W. Glover, Wednesfield.
12,283. Manufacture of Bread, W. Poole, Leicester.
12,284. Propulsion of Horseless Carriages, A. L. Fyfe, London.
12,285. Deposited Cash Protector, T. Jefferies, Birmingham.
12,286. Rotary Painting Machine, G. Thomson, Fife.
12,287. Metal, W. V. Wart, F. W. Popp, and J. J. Bradley, Birmingham.
12,288. Winding Cotton, &c., G. H. Strutt, J. Hunter, and P. Knowles, Derby.
12,289. Harbour, &c., Lights, E. de V. du Boulay, Isle of Wight.
12,290. Internal Combustion Engines, R. J. Urquhart, Manchester.
12,291. Bicycle Stand, J. D. Johnson, Manchester.
12,292. Stop Valves, S. E. Alley, Glasgow.
12,293. Carbonising Machines, J. E. Tolson, Dewsbury.
12,294. Shirts, A. Graham, Glasgow.
12,295. Bearings for Rotating Shafts, T. R. Wollaston, Manchester.
12,296. Thoroughly Ventilated Hat, H. J. Stanbury, Exeter.
12,297. Bicycle Sun, &c., Screen, W. Grosvenor-Bradley, Manchester.
12,298. Indicator for Vehicles, R. Platz and A. Packscher, Glasgow.
12,299. Specially Prepared Towel, W. Grimshaw, Manchester.
12,300. Ladies' Saddles for Cycles, &c., A. Fawsitt, Manchester.
12,301. Continuous Automatic Brake, C. Luyers, Brussels.
12,302. Railway Rail, H. Biermann, Liverpool.
12,303. Machines for Washing Ores, &c., C. E. Hall, Sheffield.
12,304. Elastic Tires for Wheels of Auto-cars, S. Griffin, Bath.
12,305. Adjustable Handle-bar, T. A. and C. D. Marshall, London.
12,306. Pneumatic Tires for Cycles, E. H. Simpson, Birmingham.
12,307. India-rubber Clip, A. Rawlinson, Horwich, near Bolton.
12,308. Tuyeres, &c., A. Ogden and R. R. Lawson, Cumberland.
12,309. Hydraulic Motor, L. Grote, London.
12,310. Boats, &c., W. H. FitzGerald, London.
12,311. Pneumatic Tires, A. Norreys, London.
12,312. Electrically Smelting Metals, J. L. Dobell, London.
12,313. Bicycle, S. F. Smith, London.
12,314. Tires for Cycles, E. J. Smith, Birmingham.
12,315. Domestic Fire-ranges, D. Harling, London.
12,316. Door Handles, W. Rayment, London.
12,317. Disinfecting Fluid, H. H. Perkes, London.
12,318. Shirt Sleeve Adjuster, H. Collings, London.
12,319. Overhead Lamps, C. Richards, London.
12,320. Sewing Machine, T. J. Roome, London.
12,321. Brakes for Cycles, J. H. Rusby, London.
12,322. Stopping Leaking Boiler Tubes, H. Jordan, London.
12 323. Puzzle, A. Hunt, London.
12,324. Flushing Cisterns, F. Price, London.
12,325. Driving Gear for Cycles, F. Müller, London.
12,326. Pneumatic Tires for Vehicles, J. H. Barry, London.
12,327. Device for Making Bread, &c., S. Murray, London.
12,328. Alloys, J. C. Bull, London.
12,329. Electrical Switches, G. Binswanger, London.
12,330. Electrical Switches, G. Wilkinson, London.
12,331. Spanner, J. P. Funt, London.
12,332. Hold-fast Hair-pin, C. A. H. Graves, London.
12,333. Hand Grips for Cycles, H. H. Grenfell and W. Tyree.—(*J. C. Alexander, Australia.*)
12,334. Lids for Hot-water Cans, &c., G. Platt, jun., London.
12,335. Axle-boxes, E. T. Hughes.—(*H. A. Byle, United States.*)
12,336. Securing Cycle Handles, A. G. Alexander, London.
12,337. Portable Engines, The British Motor Syndicate, Ld.—(*W. Maybach, Germany.*)
12,338. Oil or Vapour Burners, H. H. Lake.—(*T. R. Browne, United States.*)
12,339. Rotary Pumps, A. P. Kilpatrick, London.
12,340. Bag Handles, S. Llewellen, London.
12,341. Hopper Dredgers and Barges, W. Brown, London.
12,342. Feed Apparatus for Printing Machines, H. C. Watson, London.
12,343. Paper Folding Machines, H. C. Watson, London.
12,344. Method of Indicating at a Station whether the Telephone Lines are Engaged or Not, E. Naglo, London.
12,345. Working of Telephone Stations, E. Naglo, London.
12,346. Pencils, W. P. Thompson.—(*B. B. Goldsmith, United States.*)
12,347. Ink Erasers, W. P. Thompson.—(*B. B. Goldsmith, United States.*)
12,348. Hose Pipe Nozzles, W. P. Thompson.—(*R. Wise, United States.*)
12,349. Garment for Ladies' Wear, G. Jackson, Manchester.
12,350. Tightening Straps or Bands, F. L. Moore, Liverpool.
12,351. Incandescent Gas Lighting, W. W. Baggally, London.
12,352. Feed Trough for Poultry, J. J. Cousins, London.
12,353. Perfumed Carbonic Baths, H. Mack, London.
12,354. Flower Pot, C. J. Watts, London.
12,355. Bridle Bits, C. F. Mansuy, London.
12,356. Protective Walls for Guns, J. Vavasseur, London.
12,357. Bicycle Stands, I. V. E. Thompson, London.
12,358. Lamps, F. Clark and The Southend Gas Lighting Coke Company, London.
12,359. Rotating Boiler Grates, C. G. P. de Laval, London.
12,360. Motor Car Gearing, F. F. Wellington and E. P. Allam, London.
12,361. Means for Preventing the Improper Removal of the Contents of Letter Boxes, J. C. Sigsworth, London.
12,362. Electrical Accumulators, J. Tabrar, London.
12,363. Wheels for Cycles and Vehicles, J. Tabrar, London.
12,364. Monogram Writing Paper and Envelopes, J. E. Catty and Mansell, Hunt, Catty, and Co., Ld., London.
12,365. Chair, F. Ulrich, London.
12,366. Making Laxative Bonbons, A. and A. Müller, London.
12,367. Stays for Wire Fences, R. Haddan.—(*S. C. Davis, United States.*)
12,368. Making Artificial Stone, &c., W. Owen, London.
12,369. Construction of Cycle Wheels, F. J. Goad, London.

6th June, 1896.

12,370. Cycle Cranks, J. Ardley and V. Hughes, London.
12,371. Brakes for Vehicle, &c., Wheels, F. Hughes, London.
12,372. Taps for Drawing-off Liquids, D. McLachlan, London.
12,373. Cycle Tires, W. Hallett and C. J. Winterbourne, London.
12,374. Sauce, E. Jackson, London.
12,375. Mixture for Use in Cookery, E. Jackson, London.
12,376. Trap for Catching Rabbits, &c., I. N. Tabet London.
12,377. Cleaning the Rails of Tramways, J. Pepper, London.
12,378. Bottles, L. Classey, London.
12,379. Road Locomotives, &c., E. K. Dutton, Harrogate.
12,380. Rubber Ball Inflation Valve, H. W. Verdon, London.
12,381. Lock, R. T. Shelley, London.
12,382. Toe Clips for Cycles, E. Brown, Birmingham.
12,383. Locking Hold-fast Bolts, J. Hazlitt, Dublin.
12,384. Pneumatic Tires for Bicycles, &c., S. Sharpe, Dublin.
12,385. Stud Bottle Stopper, W. S. Malkin, Manchester.
12,386. Gymnastic Apparatus, A. McDonald, London.
12,387. Cleats, J. Linkleter and E. Kipling, Tynemouth.
12,388. Folding Step Ladders, T. T. Mercer, T. Woolfall, and The Cherry Tree Machine Company, Manchester.
12,389. Cycle and other Frames, J. Aylward, Coventry.
12,390. Ampere Hour Meter for Continuous, &c., Currents, A. W. Staveley, I. H. Parsons, and T. J. Murday, Leicester.
12,391. Sliding Pen and Pencil, A. J. Hazledene, Birmingham.
12,392. Elastic Tires for Wheels, R. Hunt, Liverpool.
12,393. Ball Bearings for the Wheels of Cycles, &c., Wolseley Sheep Shearing Machine Company and H. Austin, Wolverhampton.
12,394. Framings of Auto-cars, &c., Wolseley Sheep Shearing Machine Company and H. Austin, Wolverhampton.
12,395. Tobacco Pipes, R. H. Campbell, London.
12,396. Fusing of Chromium, &c., E. A. G. Street, London.
12,397. Horse Clippers, &c., D. Hillhouse, Dumbarton.
12,398. Covering for Electrical Conductors, L. Davis, London.
12,399. Pneumatic Riveting Apparatus, H. D. Earl, Manchester.
12,400. Boots and Shoes, F. Rigby, Manchester.
12,401. Boots and Shoes, F. Rigby, Manchester.
12,402. Displaying Cloth, &c., T. and W. Griffiths, London.
12,403. Bicycle Supports, R. O. Rowland, London.
12,404. Guards for Pneumatic Tires, R. O. Rowland, London.
12,405. Looms, J. Stukley and G. Holden, Liverpool.
12,406. Boiler Settings and Furnaces, W. Hampton, Bilston.
12,407. Forewhales of Horse Collars, G. F. Bradley, Moseley.
12,408. Boot Trees, G. H. Sankey, Wolverhampton.
12,409. Captive Golf Ball Apparatus, J. S. Porter, Edinburgh.
12,410. Saddles, S. Hancock, Nottingham.
12,411. Stretching Frame for Picture Canvas, R. C. Ertel, Hamburg.
12,412. Ladder-shaped Safety Apparatus, F. Subatzus, Hamburg.
12,413. Lifeboat with Mechanical Propulsion, R. J. Plunkett, Bristol.
12,414. Cooling Journal Bearings, P. R. J. Willis.—(*The Cook Cooler Company, Ld., United States.*)
12,415. Oil Lamps, W. Fletcher, London.
12,416. Check Pessarium, P. Wolfrom, Berlin.
12,417. Advertising Apparatus, A. E. Atkinson, Newcastle-on-Tyne.
12,418. Cycle Saddles, W. Vale, Birmingham.
12,419. Adjustable Spanner, J. Reid and W. H. Laidlaw, Glasgow.
12,420. Fixing Cuffs, F. A. Hallsworth, Gloucester.
12,421. Wheel, C. Harris, jun., and B. Ware, Dunstable.
12,422. Double-lap Pneumatic Tire, A. E. Webb, Leicester.
12,423. Movable Handle-bar for Bicycles, F. Bailey, Chichester.
12,424. Spring Tire, W. M. Bevan, Sevenoaks.
12,425. Quick-setting (Hardening) Mortar, L. Mack, Stuttgart.
12,426. Cycles, T. F. Cashin, London.
12,427. Mechanical Stud, A. Pick and M. Fleischner, London.
12,428. Slaughtering Oxen, &c., A. D. Butler, London.
12,429. Milling Woollen Fabrics, S. and B. Preston, London.
12,430. Gas for Illuminating Purposes, A. Arter, London.
12,431. Mowing Machines, H. M. Deming, London.
12,432. Cycles, G. Brand, London.
12,433. Bicycle Support and Brake, W. J. S. Strange, London.
12,434. Compound of Salicin, &c., W. P. Thompson.—(*Ludwig, Sell, and Co., Germany.*)
12,435. Parabolic Churn, A. H. Randolph and G. Gilkes and Co., Ld., London.
12,436. Moulding or Pressing Wood, W. P. Thompson, Liverpool.
12,437. Elevating and Storing Beer, M. McSwiggan, London.
12,438. Machines for Sharpening Drills, O. Larson, London.
12,439. Oil Engines, D. Clerk, London.
12,440. Tool and Air Pump, W. G. A. Edwards and E. Rüntz, London.
12,441. Power Transmitting Mechanism, P. Auriol, London.
12,442. Guard for Wheels of Cabs, F. J. Singleton, London.
12,443. Tires, H. W. Tyler, Knight, and J. F. Dowding, London.
12,444 Pneumatic Tires and Tire Covers, J. C. Grant, London.
12,445. Tires, J. Harvey, London.
12,446. Explosion Engines, J., S., F., and E. Carter, London.
12,447. Pastes, A. J. Boult.—(*C. M. Higgins, United States.*)
12,448. Cycle Lock and Foot Rest, W. James London.
12,449. Utilising Horseless Vehicles, E. Starmer, London.
12,450. Shoe Horn and Paper Knives, F. A. A. Rowland, London.
12,451. Plastic and Incombustible Material, E. Cadoret, London.
12,452. Pneumatic-tired Velocipedes, F. H. Ninlim, London.
12,453. Outer Coverings of Tires, J. Pakeman, London.
12,454. Pince-nez, Spectacles, &c., J. Pakeman, London.
12,455. Gas Burners for Laboratory Work, F. Lamplough, London.
12,456. Clearing Apparatus for Threads, B. J. B. Mills.—(*P. Perret, France.*)
12,457. Motive Power Engines, O. G. Pante, London.
12,458. Ladder Scaffolding, C. A. Sabow, London.
12,459. Mechanical Propelling Power, J. Gandon, London.
12,460. Utilising Escaping Heat of Furnaces, E. Fettweis, London.
12,461. Wheels, F. E. Harnett and G. J. R. Millington, London.
12,462. Closet Cover, J. B. V. Hosstrup, London.
12,463. Gloves, H. Charbonnier, London.
12,464. Ticket Punching, &c., Devices, D. McGill, London.

12,465. Protecting Submerged Surfaces, J. Gordon, London.
12,466. Valve Gear for Steam Engines, F. E. Andé, London.
12,467. Alloys, E. A. G. Street, London.
12,468. Nosebags, M. R. Lynch, London.
12,469. Flying Machines, G. L. A. Davidson, London.
12,470. Pistols and other Small-arms, G. V. Fosbery, London.
12,471. Feeding Envelope Blanks, J. Liebhardt and E. Fischer, Barmen.
12,472. Cycle Attachments, W. A. D. Keys, London.
12,473. Scraping Hides and Skins, C. Poullain-Beurier, London.
12,474. Voice or Speaking Tubes, J. D. Churchill, London.
12,475. Wheels, S. W. Carlton, London.
12,476. Ventilated Handles for Velocipedes, J. Gale, jun., London.
12,477. Self-propelling Road Vehicles, Société des Générateurs à Vaporisation Instantanée (Système Serpollet), London.
12,478. Portable Buildings, D. Brümmer, London.
12,479. Chain Wheels of Velocipedes, P. C. Lawless, London.

8th June, 1896.

12,480. A Mechanical Toy, F. Marsh, Manchester.
12,481. Chandelier Arms for Gas, S., T., and S. Eaton, jun., Birmingham.
12,482. Steadying Cycle Wheels, T. H. Simmonds, London.
12,483. Holding Window Blind Cords, W. Dawson, Halifax.
12,484. Beaming Mills, B. Frankland, J. W. and L. Banister, Halifax.
12,485. Puncture Resisting Appliances for Cycles, A. Koch and O. Hetterich, London.
12,486. Seating Breeches, &c., H. J. Messent, Nottingham.
12,487. Machines for Washing, J. McAllister, Glasgow.
12,488. Umbrellas, I. R. Hayes and W. Knowles, Manchester.
12,489. Locomotive Foot-plates, W. McDonnell and H. V. Morony, Limerick.
12,490. Self-starting Cycles, J. G. Inshaw, Birmingham.
12,491. Quarrying Machinery, J. Thomas, W. Stainton, and F. C. Sanders, Liverpool.
12,492. Oil Cans, A. C. Vice, Nottingham.
12,493. Friction Clutches for Cycle Axles, J. Walker, Bradford.
12,494. Polishing Military Buttons, A. T. Hackett, Birmingham.
12,495. Rail Joint for Tramways, &c., W. Roberts, London.
12,496. Self-closing Air Tire, T. Green, Kidderminster.
12,497. Gate and Door Stop, J. H. Hawksworth, London.
12,498. Fastener for Windows, J. H. Hawksworth, London.
12,499. Air-tight Casks, W. T. Bridge and G. Watson, Derbyshire.
12,500. Dyeing Apparatus for Textile Goods, H. Schirp, Germany.
12,501. Bottles, A. C. R. King, British Columbia.
12,502. Seamed Tubing, O. Pihlfeldt and W. G. Garnett, Birmingham.
12,503. Conveying Rotary Motion, J. F. Dowling, Dublin.
12,504. Transmission of Electricity, B. P. Scattergood, Leeds.
12,505. Bicycles, S. F. Smith, London.
12,506. Automatic Music Desk Book, H. R. Nathan, Devonport.
12,507. Securing Hammers, C. N. Wood, H. Stannard, and C. A. Barnard, London.
12,508. Improved Clip for Trousers, G. Grice, London.
12,509. Tires for Cycles, A. Milnes and E. Smith, London.
12,510. Teapot, J. W. Oakford, Norfolk.
12,511. Catch for Window Blind Cords, G. F. Hare, London.
12,512. Register Lock for Cycles, J. F. Jamieson, London.
12,513. Propelling Floating Vessels, F. H. Alexander, London.
12,514. Trouser Attachment for Cycling, G. T. Harrap and E. Hewett, London.
12,515. Gas Burners, &c., F. W. Golby.—(*O. Lindner, Belgium.*)
12,516. Tires for Road Vehicles, H. F. Pattinson, London.
12,517. Tempering Metallic Articles, J. S. Fairfax, London.
12,518. Surveying, &c., N. Browne.—*P. C. Neville, India.*)
12 519. Preventing Sickening of Mercury, J. T. Penny and J. Dungey, London.
12,520. Construction of Clutches, C. B. Schultz, London.
12,521. Doors, C. M. White.—(*The Flexible Door and Shutter Co., United States.*)
12,522. Bearings, M. C. P. and C. V. Thierry, G. D. Sturrock and F. F. H. L. Mennons, London.
12,523. Vegetable Soups, T. F. Garrett and W. M. Spouse, London.
12,524. Connecting Parts of Cycles, J. Ardley and V. Hughes, London.
12,525. Driving Gear for Velocipedes, J. Anderson, London.
12,526. Driving Gear for Velocipedes, J. Anderson, London.
12,527. Treatment of Air, D. Hancock, J. B. Craig and A. H. Hancock, London.
12,528. Hanging of Window Sashes, T. R. Fuller, London.
12,529. Lasting Machines, H. H. Lake.—*W. Shaw, United States.*)
12,530. Automatic Measuring Tape, G. Hildebrandt, London.
12,531. Switches, &c., A. Slatter and W. Rixon, London.
12,532. Cradles, W. Slight, London.
12,533. Railway Signalling Apparatus, R. Gascoigne, London.
12,534. Indelibly Marking Paper, H. W. Langbeck, London.
12,535. Coke Ovens, O. Imray.—(*The Firm of F. Brunck, Germany*)
12,536. Apparatus for Drying Tea, W. W. Wardle, London.
12,537. Caps, R. Thomas, London.
12,538. Automatic Lubricator, S. S. Bromhead.—(*T. H. Popp, Germany.*)
12,539. Fly Wheel for Motor Cars, &c., A. Paget, London.
12,540. Steering Mechanism for Motor Cars, A. Paget, London.
12,541. Pneumatic Tires, S. Bunting, Birmingham.
12,542. Burners, W. P. Thompson.—(*The Gesellschaft für stossfeste Glühlicht Brenner, "Patent Fritz," G. M.B.H., Germany.*)
12,543. Steam Boilers, G. J. N. Carpentier, London.
12,544. Machinery for Cutting Leather, W. P. Brough, London.
12,545. Driving Crank for Cycles, A. Appleby, Birmingham.
12,546. Automatic Air Inlet Apparatus, E. S. Price, London.
12,547. Printing Presses, M. L. W. Hallenbeck and J. B. Gibbs, London.
12,548. Patent Pedal and Pedal Crank, J. Stanley. London.
12,549. Secondary Batteries, D. G. Fitzgerald, London.
12,550. Electrical Circuit Closing Thermometers, A. Luraschi, London.

12,579. Musical Instruments, M. O. Claus, T. B. Puttmann and H. E. C. Felix, London.
12,580. Tires to Prevent Puncture, J. W. and J. Turner, London.

9th June, 1896.

12,581. Supplying Electricity, P. J. Pringle and J. M. V. Money-Kent.
12,582. Stove Guards, Fire Guards, &c., W. R. Hatton, London.
12,583. Traction Horse, A. M. Wood, Surrey.
12,584. Door Curtain Rods, A. Schmitt and L. Raiss, London.
12,585. Elevators, W. E. Langdon, Belper.
12,586. Bottle Stoppers, H. Mellars and J. D. Owen, Cardiff.
12,587. Supporting Telephone Transmitters, R. Baker, J. Filmer, E. L. Ryder, and A. Gartner, London.
12,588. Telephone Receivers, R. Baker, J. Filmer, E. L. Ryder, and A. Gartner, London.
12,589. Motors for Driving Machinery, J. McAllister, Glasgow.
12,590. Adaptable Pneumatic Handle, R. Palmer, Manchester.
12,591. Treatment of Gold, &c., Ores, J. B. Torres, London.
12,592. Shuttle Changing Mechanism for Weaving Looms, A. Johnstone and J. W. Parker, Bradford.
12,593. Disposal of Sewage, R. Johnston, Glasgow.
12,594. Manufacturing Cranks, A. J. Thurman, Birmingham.
12,595. Tea Infusers or Steepers, J. H. Sutthoff, Manchester.
12,596. Tools for Drilling Holes, E. Chatham, Manchester.
12,597. Binders for Bank Books, J. T. King.—(*J. T. Haugh and H. Reiber, United States.*)
12,598. Furnace and Grates, J. G. Sanderson, Glasgow.
12,599. Cycles, R. J. Alpe, Birmingham.
12,600. Means for Superheating Steam, A. Alison, Bolton.
12,601. Motor Carriages, J. Johnston, London.
12,602. Tricycles Actuated by Compressed Air, W. Stilton and R. A. McLellan, Birmingham.
12,603. Wheels for Velocipedes, &c., A. Daw, Birmingham.
12,604. Pneumatic Tires, W. Fletcher, London.
12,605. Protecting Parts of Trousers, C. E. White, Manchester.
12,606. Basket Lid, A. Mitchell, Guernsey.
12,607. Adjusting Chain-wheel of Cycles, H. Hind and J. Barlow, Nottingham.
12,608. Pipes for Smoking, G. McIntyre, Glasgow.
12,609. Bridging the Joints of Railway Rails, T. S. McKinnie, Glasgow.
12,610. Gas Burners, J. Schuch and H. Kneidel, Glasgow.
12,611. Cutter for Covered Wire, W. Wilkinson, Penketh, near Warrington.
12,612. Incandescent Mantel Protectors, J. W. Lea and J. H. Perrins, Birmingham.
12,613. Double-action Driving Leverage, R. Groom, Ford, near Shrewbury.
12,614. Castors for Furniture, &c., J. H. Betteley, London.
12,615. Separating Water from Steam, W. and T. W. B. Durant, Barnsley.
12,616. Treating Calendar Bowls, J. A. Holmes, Leeds.
12,617. Watches, F. Hotton, London.
12,618. Adding Machine, D. Swan, Falkirk.
12,619. Match-boxes, G. Nathan and R. Hayes, Birmingham.
12,620. Handles of Spades, &c., J. Potts, Birmingham.
12,621. Weft and Twist Cans, T. Isherwood and T. Moore, Manchester.
12,622. Spring Soles and Heels for Boots, S. S. Hazeland, Penzance.
12,623. Tramway Cars, J. Milnes, Lancashire.
12,624. Pegs for Shuttles, J. Wilson and J. Lumb, Leeds.
12,625. Attaching Brush Heads to Handles, N. Eastwood, London.
12,626. Tire for Cycles, S. J. Barnes, Birmingham.
12,627. Washing Machines, W. Geldard, London.
12,628. Universal Fuel Injector, A. Bryce, Birmingham.
12,629. Gloves, E. Oberländer, London.
12,630. Sewing Machines, F. W. Farr, London.
12,631. Combined Bicycle Pump and Rest, E. X. Damman, London.
12,632. Gas Incandescence Lamps, J. Spiel, London.
12,633. Oil Engines, J. A. Drake, London.
12,634. Driving Gear for Motor Carriages, J. A. Drake, London.
12,635. Electrical Switches, G. Senior, jun., and T. D. Dundas, London.
12,636. Drying Printers' Matrices, &c., G. Hallett, London.
12,637. Electric Machines, W. H. Cooley, London.
12,638. Looms, P. M. Justice.—(*The Weaver Jacquard and Electric Shuttle Company, United States.*)
12,639. Cycles, J. W. Ross, London.
12,640. Pneumatic Tires, E. Harris, London.
12,641. Elastic Bands for Girdles, A. and E. Hücking, Germany.
12,642. Rifle and Range Finder, A. G. B. Scuri, London.
12,643. Compressing Sulphurous Acid, E. Porák, London.
12,644. Operating Skylight Sashes, J. Woodall, London.
12,645. Colour Photography, J. W. McDonough, London.
12,646. Velocipedes and other Vehicles, B. C. Hicks, London.
12,647. Wick Tubes for Petroleum Lamps, N. D. Ingram, London.
12,648. Vehicle Wheels, J. R. Terry, London.
12,649. Devices for Sealing Bottles, L. Kalling, London.
12,650. Thermo-electric Generators, H. B. Cox and The Cox Thermo - Electric Company, Limited, London.
12,651. Inflating Pneumatic Tires, B. R. Adkins and C. Windsor, London.
12,652. Wheel Tires, T. Gee and S. Burge, London.
12,653. Surgical Belt for Women, L. Jouatte, London.
12,654. An Attachment for Cycles, A. J. Southey, London.
12,655. Children's Teething Pads, M. M. Williams, London.
12,656. Devices for Lifts and Hoists, J. T. Clifton, London.
12,657. Cycles Brake Mechanism, T. R. Johnston, London.
12,658. Hydraulic Brakes, E. J. Clubbe, A. W. Southey, and the Electric Motive Power Company, Ld., London.
12,659. Steam Pumps, H. E. Newton.—(*C. C. Worthington, United States.*)
12,660. Wrapping Newspapers, H. E. Newton.—(*R. Hoe, United States.*)
12,661. Metal Polish, H. Mason, London.
12,662. Generating Acetylene Gas, A. Tobler, London.
12,663. Turbines, &c., C. F. de Kierzkowski-Steuart, London.
12,664. Ships, M. P. Duggleby, London.
12,665. Indicator or Signal Clock, K. Haldenegg, London.
12,666. Lubricator, G. S. Eckford, London.
12,667. Gear and Chain Wheels, L. E. Mongiardino, London.
12,668. Window Fastener, W. F. Taylor and J. McLeod, London.
12.669. Brake for Bicycles, &c., J. T. Todman, London.
12,670. Hoisting Device, C. A. Jensen.—(*A. F. Regan, United States.*)
12,671. Switches, W. D. Murphy, London.
12,672. Cranks for Velocipedes, &c., J. Hutson, London.
12,673. Cement for Plastering on Walls, C. Marson, London.
12,674. Covering Walls with Plaster, C. Marson, London.
12,675. Pins, C. Wenigmann, London.
12,676. Dynamometer, J. B. Granjon, London.
12,677. Injection Syringes and the like, F. Freienstein, London.
12,678. Transmitting Force, S. Hartmann and H. Bultmann, London.
12,679. Substitute for Wadding, M. Rosenbaum, London.
12,680. Elastic Wheel Tires, E. Girod and F. J. Wich, London.
12,681. Buckles for Wagon Springs, W. G. Moreton and J. Mitchell, London.
12,682. Multiple Pulp Papers, W. A. Kershaw and the Medway Paper Mills Company, Ld., London.
12,683. Acetylene Gas, H. A. Deroy, London.
12,684. Driving Cycles, A. M. A. Struben, London.
12,685. Rail Bonds, L. Cook, London.
12,686. Metal Belting for Pulleys, &c., L. Othon, London.
12,687. Non-slipping Devices for Tires, E. J. Pennington, London.
12,688. Self-propelled Vehicles, E. J. Pennington, London.
12,689. Explosion Engines, H. Clifford and W. Baines, London.
12,690. Pattern Cards, L. Kleinberg and J. Szczepanik, London.
12,691. Discharging Cargo, A. J. Boult.—(*J. W. Glaholm, Canada, and C. Salmond, United States.*)
12.692. Driving Gear for Bicycles, J. Westaway, London.
12,693. Treatment of Wood, Paper, &c., S. Bennett, London.
12,694. Water Wheels, A. M. Pascault and J. F. M. H. de Coursac, London.
12,695. Bicycles, A. B. Lewis, London.
12,696. Accumulators, X. M. Roux, London.
12,697. Fire-grates, H. H. C. Jürgens, London.
12,698. Culinary Vessels, R. C. Cole, London.
12,699. Cartridges, C. Trossy, Liverpool.
12,700. Gun Wads, C. von Witzleben and M. Thorn, Liverpool.
12,701. Stopcocks, J. Watkinson, Liverpool.
12,702. Draught Ropes of Steam Trawlers, W. B. Brown, Liverpool.
12,703. Adjusting Saddles to Cycles, J. S. Reynolds, Wolverhampton.

10th June, 1896.

12,704. Match Striker on Pipes, S. B. Porter, Portsmouth.
12,705. Bicycle Brake, L. Hopcraft, Brentwood.
12,706. Effervescing Beverages, J. R. Nixon, Gateshead.
12,707. Fluid Weighing Machine, E. F. Shannahan, Abbeydorney.
12,708. Oil Cans, J. W. Kaye, Bradford.
12,709. Chain Wheels, E. and E. Hodgson, Manchester.
12,710. Double-handed Locks, G. H. Burrows, Wolverhampton.
12,711. Curtain Suspender, V. Bennett, Swansea.
12,712. Frames for Photographic Pictures, B. Hodges, London.
12,713. Cycles and other Vehicles, &c., W. Rourke, Croydon.
12,714. Pedestrial Locomotion, J. C. and M. C. Hall, London.
12,715. Pneumatic Tires for Vehicles, E. Dutch, Manchester.
12,716. Venetian Blinds, W. L. Duncan, Glasgow.
12,717. Printing on Match Boxes, R. Hannan, Glasgow.
12,718. Tobacco Pipes and Cigar Holders, J. R. Boulcott, Birmingham.
12,719. Gear Cases for Cycles, M. H. Galsworthy, Birmingham.
12,720. Wheel Tire and Rim, A. Appleby, Newcastle-on-Tyne.
12,721. Machine Rest and Tool Holder, H. Sutcliffe, Halifax.
12,722. Tobacco Pipes, E. Stocks, Halifax.
12,723. Lamp Glasses, G. Hookham, Birmingham.
12,724. Picking Mechanism, J. Smith, J. Whitaker, and N. Wilkinson, Bradford.
12,725. Turning Taps, F. S. Smith and J. H. Smith, Derby.
12,726. Hygienic Crossed Legged Bed, E. Martyn, Southwold.
12,727. Clothes-prop, W. F. Horn, Liverpool.
12,728. Mowing and Reaping Machines, E. Hewitt, Buxton.
12,729. Travelling Case for Bicycles, B. F. Cocker, Sheffield.
12,730. Portable Shaving Appliance, T. F. Senior, Sheffield.
12,731. Cop Winder, B. M. Knox, Glasgow.
12,732. Pneumatic Tires, T. Wright, Glasgow.
12,733. Preventing Clock Weights Falling, F. S. and J. H. Smith, Derby.
12,734. Cycle Automatic Alarms, H. Hind and J. Barlow, Nottingham.
12,735. Filtering Sewage, W. T. Whitehead and J. Wolstenholme, Manchester.
12,736. Manufacture of Tobacco, R. Pserhofer, Manchester.
12,737. Twisting Fibrous Substances, G. Whitaker, E. Feather, and J. B. Ratcliffe, Keighley.
12,738. Distributing Electric Light, V. Planques, Brussels.
12,739. Disinfecting Fountain, W. G. Ashburner, Dalton-in-Furness.
12,740. Wire Fabric for Mats, F. W. Crossley and S. H. Shenstone, Birmingham.
12,741. An Improved Gear, H. G. Cadney, London.
12,742. Sanitary Infant's Bib, &c., L. B. Baldock, London.
12,743. Fasteners and Binders, &c., E. B. Parnell, London.

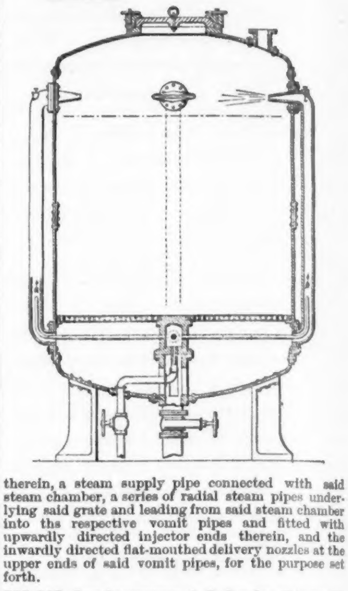
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

555,486. Bleaching Keir, *G. L. and W. P. Allen, Worcester, Mass.—Filed July 15th*, 1895.

Claim.—In a bleaching keir, the combination, as described, with the main body shell, and the grating separating the interior into an upper and lower space; of the series of vomit pipes leading from the lower to the upper space, disposed adjacent to the exterior of the main body with their inwardly curved ends attached to said body shell, the central grate supporting column below and terminating at the grate, and having the supply head with interior steam chamber therein, a steam supply pipe connected with said steam chamber, a series of radial steam pipes underlying said grate and leading from said steam chamber into the respective vomit pipes and fitted with upwardly directed injector ends therein, and the inwardly directed flat-mouthed delivery nozzles at the upper ends of said vomit pipes, for the purpose set forth.

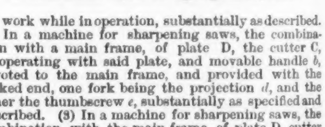
555.486



555,567. Saw Sharpener, *C. H. Douglas, Chicago, Ill. —Filed July 16th*, 1895.

Claim.—(1) In a machine for sharpening the teeth of saws, the combination with the main frame, of the plate D attached thereto and arranged to rest upon the back of a tooth; the cutter C, constructed to fit the circularly grooved face or front of the tooth and arranged to act in conjunction with said plate D in removing the metal from the point of the tooth, thus giving the required angle to the point of the tooth, and avoiding the formation of a burr on the cutting point; and means for keeping the cutting tool up to its work while in operation, substantially as described. (2) In a machine for sharpening saws, the combination with a main frame, of plate D, the cutter C, co-operating with said plate, and movable handle *b*, pivoted to the main frame, and provided with the forked end, one fork being the projection *d*, and the other the thumbscrew *e*, substantially as specified and described. (3) In a machine for sharpening saws, the combination with the main frame, of plate D, cutter C, movable handle *b*, provided with the clamping device; and the adjustable plate E, mounted eccentrically upon the main frame, substantially as described.

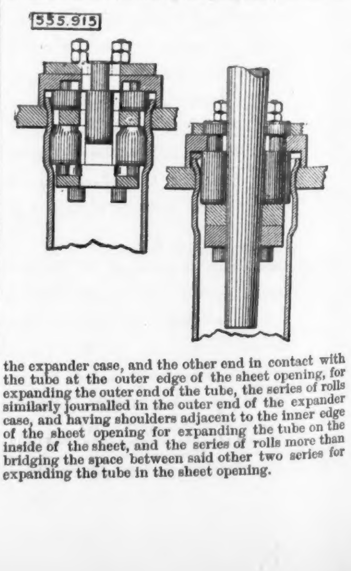
555.567



555,915. Flue Expander, *J. T. Fuhrmann and J. M. Daugherty, St. Paul, Minn.—Filed June 9th*, 1893.

Claim.—(1) In a tube expander, the combination of the cylindrical rolls adapted to be brought into contact with the tube on each side of the sheet, and the intermediate rolls bridging the space between the first-named rolls and having half the taper in an opposite direction of that of the mandrel, substantially as described. (2) In a tube expander, the combination of the series of rolls having end gudgeons journalled in the expander case, and the other end in contact with the tube at the outer edge of the sheet opening, for expanding the outer end of the tube, the series of rolls similarly journalled in the outer end of the expander case, and having shoulders adjacent to the inner edge of the sheet opening for expanding the tube on the inside of the sheet, and the series of rolls more than bridging the space between said other two series for expanding the tube in the sheet opening.

555.915



THE CONVENTION OF THE MUNICIPAL ELECTRICAL ASSOCIATION.

As promised in our last impression, we conclude our report of the proceedings at the Convention. The third paper was on

THE CONTROL BY MUNICIPAL AUTHORITIES OF CONSUMING DEVICES AND THE WIRING CONNECTING THEM TO THE MAIN,

by C. H. Wordingham, the city electrical engineer of Manchester. It was taken as read, the author merely giving the headings of the subject. The following is an abstract of the paper:—The author stated that the subject of regulations as to carrying out the connection within a consumer's premises of his consuming devices to the electric supply mains is one which has engaged the attention of electrical engineers since the early days of electric lighting. The points with which the author desired to deal were those especially affecting municipalities, the questions of the regulations themselves might be thrashed out by such societies as the Institution of Electrical Engineers or the Northern Society of Electrical Engineers. Before making regulations it is well to see whether the body making the regulations has power to enforce them. By the Board of Trade regulations, supply must compulsorily be discontinued if the insulation resistance of an installation does not reach 10,000 ohms, but most certainly if the insulation resistance exceeds this amount the undertakers cannot of necessity be compelled to connect, although most wiring contractors seem to suffer from the delusion that this is the case. It is, however, most clear that municipal bodies under their provisional orders have the power to make such regulations as to work on a consumer's premises as shall prevent him becoming a source of danger or unsatisfactory supply to any other consumer, and the author quoted the clauses in the order as follows:—"Provided also that if the owner or occupier of any such premises as aforesaid uses any form of lamp or burner, or uses the energy supplied to him by the undertakers for any purposes, or deals with it in any manner so as to unduly or improperly interfere with the efficient supply of energy to any other body or person by the undertakers, the undertakers may, if they think fit, discontinue to supply energy to the premises as long as such user continues." "Provided also that the undertakers shall not be compelled to give a supply of energy to any premises unless they are reasonably satisfied that the electric lines, fittings, and apparatus therein are in good order and condition, and not calculated to affect injuriously the use of energy by the undertakers or by other persons." Supply station engineers may wish that the Board of Trade would allow a municipality to draw up regulations and to submit them to the Board for approval, such regulations being endorsed by the Board and becoming binding on consumers.

Municipal authorities already interfere to a large extent with the consumers' premises, notably in the case of sanitary arrangements, and water and gas supply; and, from the author's experience, there can be little doubt that consumers of electric current would gladly welcome some efficient supervision on the part of the municipal authorities. It must be notorious to all present that in every town there are many contractors whose one aim and object is to obtain work at any price, and then by scamping the work to make some profit. The last thing they think of is to make a good, durable, and efficient job. Cheap and inefficient wiring is a crying evil at the present time. Other means must be sought for preventing bad work than those now held under the provisional order. Glasgow has obtained it by a side wind in the most ingenious manner. Clause 65 of the Glasgow Buildings Regulation Act, 1892, runs as follows:—"Any installation for electric light in any building shall be subject to such regulations and conditions for securing the safety of the public, and for the prevention of fire, as the Lord Provost, magistrates, and Town Council of Glasgow, being the Authority empowered to supply gas and electric light within the city, may reasonably require."

The author thinks it would be desirable for the Corporation to be able to constitute themselves through their engineer an advisory body to the consumer who chose to avail himself of their advice; that is to say, any consumer, no matter how small, could, by the payment of a fee, small in the case of very small consumers, obtain the services of the Corporation to draw up a specification for the wiring, and to watch the carrying out of the work, power being given as in an ordinary specification to have the work done in a definite predetermined manner. The author then said that many possible consumers are lost—some because the matter is not properly put before then, others because they do not care to trust to an ordinary contractor, others because they are so trusting to as think that a supply can be produced more cheaply by their own plant, and lastly those who seek expert advice, but who are unable to distinguish a consulting engineer from a contractor masquerading as such. Who could be a better qualified person to give advice than the engineer to the Corporation, who is presumably endowed with the same feelings that actuate the members of the Corporation, viz., that a Corporation exists for the good of the citizens generally? The author is quite aware that the proposal here made is likely to lead to violent opposition from consulting engineers, and this raises the whole question of municipal control *versus* private enterprise. Once the principle is admitted that certain undertakings are best placed in the hands of the Corporation, it is difficult to see why the idea should not be carried out in its entirety, and consumers not only supplied with current but guarded in such a manner that they can make proper use of the supply. The fee charged, except in the case of very small consumers, would be comparable to the fees charged by consulting engineers, and the author believes that the practice of the latter body would be increased.

Another remedy would be for the Corporation itself to employ a staff of workmen, and carry out the wiring. This he thought unwise, as there would be considerable risk of financial loss. The consumer would regard the work as guaranteed; there would be difficulty in enforcing regulations upon contractors: and such objections to competition as apply to consulting engineers would apply still more to wiring contractors. It is desirable for the Association to draw up rules, and these should include all the points desired by the supply station engineers, and also by the fire offices. Insulation need not be so high on alternate current systems, where there is a separate transformer in each house, or where a number of consumers are fed from a sub-station, as where a direct current supply is given. The task of drawing up rules should devolve upon a committee of the Association, and he suggested points to be discussed. The insulation resistance should be decided, and it is no use requiring such a standard as can only be attained by drying the switches and fittings with calcium chloride, and warming the ends of the cables with blow lamps. Allowance should be made for exceptional circumstances, and the standard should not be enforced in new buildings with wet plaster until the plaster has had time to dry. Quality of cable, the nature of its insulating covering, and the method of supporting the wires should also be defined. Secondly: The distributing boards must be so arranged as to allow of efficient balancing; regulations should be made as to starting and stopping motors and the adjusting of arc lamps, so that excessive currents at starting shall not be required. Thirdly: As one of the conductors will probably be earthed, precaution must be taken to prevent a consumer getting an electric shock. Motors should be so designed that the brushes will not require attention.

Notice should be given to the Corporation before the work of wiring is begun, so that proper tests may be made; also, samples of the materials should be submitted for tests, and samples of switches, cut-outs, distribution boards submitted for approval, and the more important, if not all, should be tested and stamped by the Corporation, as is done with water fittings. Much might be done to raise the standard of work done by wiring contractors were a system of authorising electric light fitters to be drawn up. There are practical difficulties in the way, and questions would arise such as—Should the contracting firm or the individual workman be authorised? Should the municipal authority make the inquiries, and, if necessary, hold an examination? Or should it accept the examination of such a body as this Association, or the Institute of Electrical Engineers, or the Northern Society of Electrical Engineers? What power has the municipal authority to insist upon the authorisation of such fitters?

The following resolutions were proposed for adoption by the Convention:—

Resolved: "That this Convention of the Municipal Electrical Association is of opinion that the need of a standard set of regulations for controlling the fixing and connecting of consuming devices supplied from municipal electric supply stations is urgent, and that such regulations should be drawn up and adopted by the members of this Association."

Resolved: "That a sub-committee of members of this Association be formed to draw up a draft set of regulations, and to inquire what powers exist for enforcing such regulations, when made, and also to ascertain how further powers for this purpose may be obtained, if necessary. The sub-committee to have power to confer with any person or body of persons having special knowledge of or interest in the matter, and subject to the approval of the Council of this Association, to obtain legal advice on the matter. The sub-committee to present a full report of the work to the next Convention."

The discussion then followed.

Mr. Taylor, of Liverpool, said that, according to the author's views, both the consulting engineer and the contractor were to be improved out of existence. In Liverpool all the important work was done by the Supply Company; there are, however, a large number of contractors who take the work at very low prices, and cannot do the best work. The speaker stated that he was an inspector for the Supply Company, and remarked that the fire offices could not stop bad work, as the majority of the consumers do not pay sufficient premium to recoup the fire offices for inspection. If there were more fires the inspection would not be improved, but the rates demanded would be higher. Rules should be drawn up so as to form a specification, as it is an invidious task for an inspector to have to go to an experienced engineer and tell him his work is bad.

Mr. Hammond said that at the Westminster Conference summoned by the Board of Trade electrical engineers did not get all they desired. This association would, however, be able to put the matters before the Board. The bad wiring contractor should be got rid of. The municipality should draw up stringent rules, and the municipal engineer should have the power to inspect work and to be paid for it. Opposition from consulting engineers need not be feared, as the better the class of work the greater would become the demand for consulting engineers.

Mr. Chamen—Messrs. Crompton and Co.—said that the firm with which he was connected were dropping out of electric wiring. They should, however, like to have a strong set of rules. He thought it a bad plan for the Corporation to take up the actual work of wiring, but they should have full control over the work done.

Mr. Raworth—Brush Company—said electrical installations require very little regulations; the very worst was much better than the best gas installation. The business of fire offices was to collect fees, and not to inspect. In 1881 some winter gardens were lighted by electricity, and 20 per cent. reduction was allowed on the fire insurance premium, but no such reduction could now be obtained, so that it paid the offices better than formerly. On the Continent the work was so bad, engineers would have a fit on the spot if they saw it. The best work was worse than the worst English work. A combination of skill was required to produce such effects as those shown by Mr. Wordingham. He thought rules should not be forced on to consumers. In gas-fitting perfect freedom was allowed. The Municipal engineers' services might perhaps be made available on payment of a fee.

Mr. Manville thought a consensus of opinion ought to be obtained as to rules. The question as to whether local authorities should fit up houses was a very delicate one, as they would compete with the present contractors. Penny-in-the-slot meters for electricity would doubtless soon be employed. Progress was hindered in electric lighting by the fact that many leases had only a short period to run; perhaps the local authorities might fit up such houses on rental.

Mr. Arnot, Glasgow, agreed that the standard of certain contractors was very low, but he thought municipal engineers should not have any further responsibility thrown upon them; it was impossible to inspect while wiring was going on, and he thought they should not undertake to stamp instruments and fittings.

The meeting then adjourned, and in the afternoon the members paid a visit to the Deptford station of the London Electric Supply Corporation, Limited, and were received by the chief engineer, Mr. P. W. d'Alton, and by the manager and secretary, Mr. R. Stewart Bain.

On Thursday, 11th June, the first paper taken was on

THE COST OF ELECTRICITY SUPPLY,

by Arthur Wright, borough electrical engineer, Brighton, and President of the Association. We give the following abstract:—The author pointed out that no manufacturing undertaking can be considered to trade on a sound commercial basis, unless it has ascertained with some degree of accuracy the cost of supplying the commodity it produces; but although electricity has been regularly supplied by large undertakings for five or six years, no definite basis has yet been agreed upon by which the cost of energy wasted in feeders, transformers, shunted meters, &c., can be estimated, or tariffs arranged for such varying classes of consumers as street lamps, motors, business premises, electric tramways, &c. The author points out how charges vary; in one town discounts are given on the total consumption, and in others the price depends on the time of day during which light is used. Current for motors is charged at a lower rate than for light, and street lamps are charged for in all sorts of ways. No proper method of profit-and-loss account has yet been agreed upon by central station managers. One method is, of course, to take the total cost and divide it by the total units supplied, and take that as the basis; but this is not a correct method for the different classes of consumers. Dr. Hopkinson pointed out that the cost of supplying electricity cannot be correctly defined at so much per unit unless the *rate* of supplying that unit be also stated. The author believes that no one has yet made public the results of applying the Hopkinson method to actual accounts. He, therefore, described modifications of the method as applied to the accounts of the Brighton Corporation.

Costs are divided into "running costs" and "standing-by costs." Under the former heading are included coal, oil, and water, and a few other engine stores, besides those repairs to the steam and electricity generating plant which are caused by the continued supply of electricity to consumers. Under "standing-by costs" must be included all coal and oil used in getting up steam, and in keeping the machinery and mains in a position to supply electricity to the consumers at any time; also all stores used in the station or on the mains; all the wages debited to revenue account, as in practice these do not vary from month to month with the output of electricity; repairs to buildings, mains, meters, and those repairs to plant, &c., which are due to it having to be kept in a position to supply electricity; all rates and taxes, management expenses, insurances, and all provisions for redemption of capital and interest on them, and for the creation of any reserve or depreciation fund it may be decided to form for the purposes of preventing any cessation of the supply at any future time. The figures for the Brighton undertaking were as follows:—

	The amount spent in coal.	Engine stores.	The units sold durin these months.
In the three months of October, November, and December in 1895	£ 990	£ 201	366,040
In the three months of May, June, and July	365	133	109,662
The differences between the figures are	625	68	256,378

By the rule described in detail by the author in the paper, the running cost for coal during these six months was,

$$\frac{625 \times 240}{256{,}378} = 0{\cdot}584\text{d. per unit.}$$

For oil and stores,

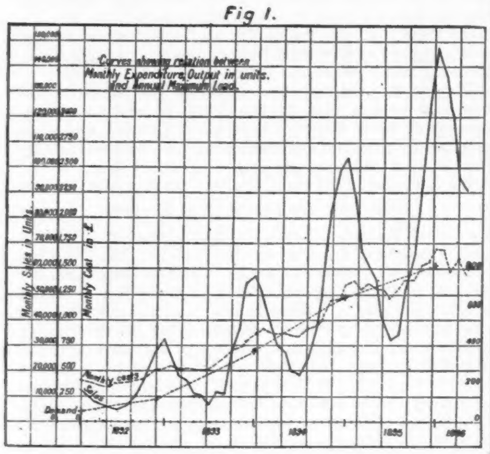
$$\frac{68 \times 240}{256{,}378} = 0{\cdot}063\text{d. per unit.}$$

Division of the Debtor Side of the Brighton 1895 *Revenue Account into Running and Standing-by Items.*

Item.	Rate per unit for running costs determined by above method.	Total running costs for the 867,500 units sold.	Total standing-by costs.	Total amount spent on the items during 1895.
	d.	£	£	£
Coal	·584	2111	485	2596
Stores	·063	230	302	532
Repairs to plant	·063	230	147	377
Repairs to buildings ..	—	—	59	59
Repairs to meters	—	—	69	69
Repairs to mains	—	—	463	463
Wages	—	—	1719	1719
Rates and taxes	—	—	327	327
Management	—	—	1838	1838
Insurance	—	—	69	69
Interest and sinking fund	—	—	7777	7777
Totals	·71	2571	13,255	15,826

The author states that the foregoing values are closely confirmed by quite a different method described later on based on the analysis of the different years' expenditure curves into the different terms of an equation obtained empirically. If the total monthly expenditures as above defined from soon after the starting of the undertaking be plotted in the form of a curve, such as the dotted curve in Fig 1, the corresponding sale of units is discernible but if the maximum annual load taken off the mains be plotted on the same diagram, as shown by the crosses, then an obvious tendency is apparent after the first or second year for the monthly total expenditure to follow this line. At Brighton the original unproductive outlay incurred on starting the undertaking was 6·3 per cent. of the total.

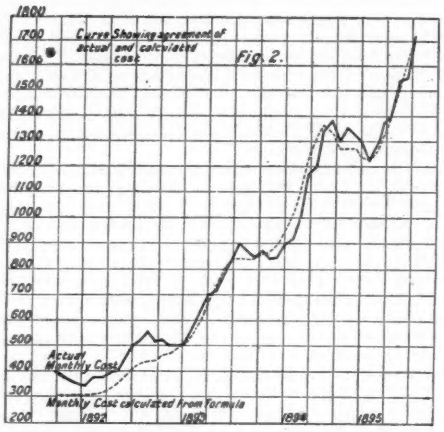
Fig 1.



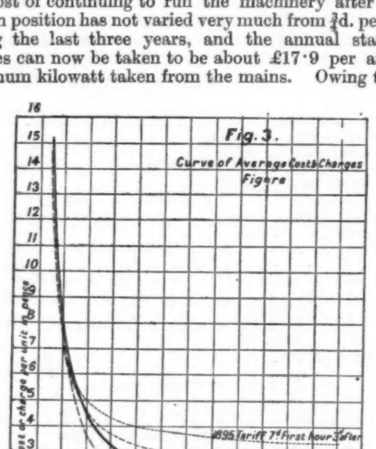
The running costs were 16·3 per cent. of the total, and if coal could there be obtained for 10s. per ton, as in the North, the cost would fall greatly. Hence there is greater necessity for a differential tariff in towns where coal is cheap than where it is dear.

The formula from which the dotted line in Fig. 2 is calculated is that found most nearly to fit the last three years' curves, and is as follows:—

$$\text{Total monthly expenditure in } £ = £190 + 1{\cdot}25 \times \text{D} + \frac{\text{units sold per month}}{300},$$



where D is the value in kilowatts on the gradually increasing maximum load-line of Fig. 1. The cost of continuing to run the machinery after it is once in position has not varied very much from ¾d. per unit during the last three years, and the annual standing charges can now be taken to be about £17·9 per annual maximum kilowatt taken from the mains. Owing to the varying time of day at which the different consumer's heaviest loads are taken, the maximum load is now only 66 per cent. of the sum total of the consumers' maximum demands. Therefore, the Corporation assumes that each kilowatt costs 66 per cent. of the £17·9, or £11·8 per annum, which works out to nearly 7¾d. per day per kilowatt, and the previously determined figure of 0·71d. per unit for running expenses enables the cost of supplying electricity to any consumer in Brighton this year to be very closely ascertained, and from these data the curve of costs Fig. 3 has been drawn. It follows from the above calculations that if all consumers paid 8½d. per unit for the first 365 hours in the year they used their demand, and ¾d. for all units consumed afterwards in the year, the undertaking would be in a self-supporting condition. The maximum charge for Brighton is, however, fixed at 7d., so by the tariff now in force, each consumer pays 7d. per unit for the first 365 hours in each year he uses his demand, and 3d. afterwards. The author finds that loss was incurred in supplying all consumers at Brighton during 1895 who used their demands less than 600 hours per annum. The result of the method of analysis used by the author is to confirm Dr. Hopkinson's startling conclusions.



The author draws a number of conclusions, some of which are as follows:—It is the duty of municipalities to charge a uniform rate of profit on the cost of supplying electricity, rather than a uniform price to all consumers, and much more so in the case of electricity than with gas, because of the much greater percentage the standing charges bear to the total cost in the former than in the latter case. The extremely low price at which electricity can be profitably supplied to consumers after they have paid off their proportion of the standing charges much more than compensates for the difficulty of understanding a uniform rate of profit tariff, as shown by the increasing rate of receiving applications for electricity in towns where differential charges and low prices to long users are in vogue. It costs two and a-half times as much to supply a unit to a consumer who uses his lights on the average only one hour per day, as it does to another who uses them three hours. It is much more worth while trying to improve the load factor than to reduce the coal bill. The rapid fall in the cost of supplying electricity as the average time of use increases makes the small householder a much more profitable class to supply both in his residential and shopping districts than the residences and shops where the wealthy dwell, owing to the frequent absence from home of this class and the early closing of their shops. One of the most important consequences of the fact that electricity can be profitably supplied from central stations to consumers at the rate of 8½d. per unit for the first 365 hours in each year they use their demand, and for something between ½d. and 1d.—according to the price of coal—for any electricity consumed afterwards in the same year, is that street lighting and that of basements or dark buildings lighted all day long can be more cheaply done by electricity than by any form of artificial light, as in those cases where the use is on the average eleven hours per day, or 4000 hours per annum, the inclusive cost for the electricity consumed will not generally exceed 1½d. per unit. The fact that up to the present only the very fringe of street lighting has been touched by the electricity supply undertakings appears to the author a sure sign that Dr. Hopkinson's conclusions have been hitherto ignored by most of the responsible managers, and again to direct and urge them to give their closest attention to these conclusions has been the object of the author in writing the paper. The discussion upon the paper then followed.

Mr. Mavor said he believed differential rates were useful, but thought Mr. Wright's system very complicated; he thought his own system better. For example, he would use a recording current meter, and suppose a person had an installation of 1000 lights, he should divide the total record by 500 ampères, and so get the average hours per light; then for, say, 1000 hours' consumption the consumer would get a discount of 10 per cent., for 2000 hours' 20 per cent., and for 3000 hours' 50 per cent. Some would get current under 3d. per unit. Large telephone stations were relatively more expensive to work than small ones, and this applies to electricity stations; also street lighting by arcs costs much more than gas lighting; incandescent lighting can be carried out at the same price as gas, but the speaker saw no advantage in it.

Mr. Sayers, Bournemouth, said he had got his company to adopt Mr. Wright's plan, and they had had an increase in the number of units sold, showing that a greater value was taken at the reduced price. He thought Mr. Mavor's system impracticable, as notice was not always given of alterations in lights and deception was easy. The general use of the light by the poor should be encouraged. At Bournemouth an extra unit costs 0·8d. If the extra units were sold at 1·5d. to 2d. per unit, a profit would be made if the maximum demands were not increased. In the first quarter of the present year they received 15 per cent. more with Wright's system than for the first quarter of 1895, although the price is now lower.

Mr. Alexander Siemens said he was quite surprised to find how dear electricity was; he had no idea of it until he had supply from the public mains in his own house. He had all the servants' rooms and the basement lighted, and found his electricity bill at 8d. per unit exactly the same as his gas bill at 3s. per 1000 cubic feet previously.

Mr. Ellis, Southport, said that at first all customers got the same rate of discount. In 1895, however, the demand system was adopted, and 30 per cent. of their customers got the current at the low rate of 7d. per unit for the first two hours, and after that 4d. per unit. The small tobacco shops and small grocers' shops paid the best. The maximum demand is now reduced to one hour, and they were afraid their income would be reduced; but it had increased 18 per cent.

Mr. Wordingham thought Wright's system good with a fixed charge of, say, £12 a-year per kilowatt demanded; that is, reckoned on the total lamps, and then a charge of 2d. per unit actually consumed; but when the system is founded upon the maximum lamps, it discourages the fixing of new lamps. In Manchester they could not spread their accounts over two quarters, which was necessary with Wright's system. Mr. Mavor's system he thought very bad, as a consumer could actually diminish his bill by using more current. Mr. Wright's figure of £11 8s. was very similar to his figure of £12 in Manchester.

Mr. Dawbarn would like to see a table setting forth the relative value of the various classes of consumers; they would be able to get the probable maximum demand, and therefore the revenue.

Mr. Geipel thought the first capital cost was a very important item, and this varied per kilowatt from £125 at Brighton to £50 at Bradford and Leicester. In many private houses 75 per cent. of the electricity account would be found to be due to the consumption in the basement.

Mr. Proctor, Bristol, thought a day load meter better than that of Mr. Wright. In Bristol the figures had been improved solely by the education of the users in the matter of switching off their lights when not required.

Mr. Hammond said the paper brought forward by Mr. Wright was a most important one; it showed clearly that the poor man was the consumer who was profitable, and not the rich man. He then illustrated this by reference to the Bowery district of New York, and by the case of Brighton itself. The Hove district did not pay.

The sixth paper was then taken on

CABLE SPECIFICATIONS AND TESTS,

by Joseph A. Jeckell, Borough Electrical Engineer, South Shields.

The author divided persons who issue specifications for cables into various classes, but only referred to one class, viz., those who know what they want and are desirous of obtaining it on the most favourable terms. It is not at all fair to contractors for an engineer to issue an open specification when he has a very clear idea what cable he intends to have. The manner of clearly specifying what is wanted seems to be best for all parties. Another reason for clearly stating what manner of cable is required is that there will be much less difficulty in stating what tests the cable will be required to stand, for those which are suitable for a rubber cable are unsuitable for a compound cable, and *vice versâ* perhaps. The best makers of copper wire are prepared to guarantee 100 per cent. when gauged over the tin. If the price lists of the various makers are examined, it will be found that there is a very considerable difference between the conductive resistance of cables. A very simple way to get over all difficulties, and to obtain just what is wanted, is not to give the number of strands and their size in the specification, but simply to specify what resistance per mile the conductor is to have, and the number of strands of which it is to be composed, and if desired, the conductivity of the copper. But this does not much matter, because it makes no difference to the engineer whether the cable manufacturer uses 98 per cent. copper and puts more in, or 100 per cent. and puts in less. What he does want is that the cable shall have a certain conductivity per mile, and he has based all his calculations on this. All strands should be cabled and not twisted, as by the latter process the wires are hardened. If concentric cable is to be used care should be taken to specify that the outer conductor must have the same copper resistance as the inner, for if the outer has the same sectional area as the inner, its resistance will certainly be more than that of the inner. It has been known to be as much as 7½ per cent. more, but this is rather an outside figure. As to insulation, if rubber is to be used it is well to specify that the layers should be well vulcanised together, and the tape next the rubber must be broad. High insulation resistance *per se* is no use; insulation is required which will not deteriorate.

About 5000 megohms per mile is a very fair insulation to require for a first-class rubber cable; and, of course, this test should be made with a battery having at least 500 volts. It is very undesirable to insist on high insulation resistance in compound cables. Great care should be taken in accepting a compound cable having a high insulation resistance; a pressure test is of much more value. Bending tests are necessary for compound cables; it must be proved that the insulation is not damaged by any bending that does not damage the lead.

The makers of the cables should also lay them, otherwise they could not guarantee them. The author, however, does not advocate letting the trench work to the cable manufacturer. It is difficult to specify what the insulation resistance of compound cables should be, because it varies with the insulating substance. It seems desirable that the life of a cable should be guaranteed; but most makers will not guarantee unless their own men make all joints after the cable has been put down.

The discussion followed. Mr. Wordingham, Manchester, said a good specification was essential. A high insulation resistance test does not prove that one contractor should not be allowed to lay the pipes and another to draw in the cables. Samples of the cables should be tested to destruction to find the breaking stress.

Mr. Talbot, Nottingham, speaking of guarantee, said he had £8000 worth of cable guaranteed for three years, and after two years his corporation still owed £800.

Mr. Alex. Siemens said rubber cables unless covered with lead were no good in places where they are alternately wet and dry. There was a crazy desire for high insulation resistance tests. Pure rubber deteriorates much more rapidly than vulcanised rubber. The use of pure rubber next the wire is a mere fad, and costs a great deal. Jute insulated lead-covered cables last splendidly; this material, and also paper, do not offer so high a resistance to sparking through as some other types. His firm had just brought out a new material which offers great resistance to sparking through, and he added particulars of the tests.

Mr. Arnot, Glasgow, said the life of the lead was the life of the cable. Mr. A. H. Preece had drawn up an equation for determining the proper thickness of lead for a given outside diameter of cable.

Mr. Callender desired to have a specification stating that the cable must pass certain tests; the conductivity per 1000 yards should be specified. He had made fibre cables up to 15,000 megohms per mile. Armouring should be carefully specified.

Mr. Crompton said the rapid deterioration of rubber

"THE ENGINEER"

was due to chemical action, and the full details were only known to the cable makers; if vulcanising were not carried out properly the results were bad. In India he knew rubber cable never lasted over two years. Callender's was the only type he had found to stand; the cables he had put down in 1882 were still in use.

The meeting was then adjourned, and the members were received in the afternoon at the Vestry Hall, Upper-street, Islington, by the Electric Lighting Committee. The following paper was then taken as read:—

Combined Electric Lighting and Traction Plants,

by John Hesketh, Electrical Engineer to the Government of Queensland, late Borough Electrical Engineer, Blackpool; and John H. Rider, Borough Electrical Engineer, Plymouth.

The author points out that the one thing operating against the cheaper production of electricity for lighting purposes is the smallness of the load factor. No suggestion for improving the factor has found such favour as the one for providing a load for the plant during the hours of daylight.

Many corporations own but do not work their tramways, and in the near future it may be safely prophesied that those corporations who willingly lease their lines will be in a minority. When a revision comes, electricity will no doubt be considered as a source of motive power, but there will be one important question to decide, viz., shall the plant be separate and distinct, or shall it be combined with a plant for electric lighting? As the plant will already exist in many cases for electric lighting upon a system unsuited for direct application to tramway purposes, the tendency may be to keep the plants separate. To show that this tendency is wrong is the object of the paper. Such a combination has already been used in America, Europe, and elsewhere. In cases where low tension direct current is in use for lighting, the question is very simple—motor transformers can be used; in fact, be the voltage and current what they may, this method can be adopted and produce a suitable direct current at 500 volts for the cars.

Such a combined plant, worked economically, ought to produce current for all purposes at 1½d. to 3d. per unit, according to the demand, simply due to the better load factor. The authors then quote facts from continental work. In Geneva the street car company takes a minimum of 500,000 units per annum, and pays 1·15d. per unit. In Hamburg the street car company guarantees a minimum annual consumption of 2,500,000 units, and their whole expenses are 3·95d. per car mile. The number of persons carried has increased 32 per cent. over that when horse cars were used, and the receipts have increased nearly 35 per cent. In Havre 1·75d. per unit is paid by the tramway company. There are two systems applicable: (*a*) A separate and distinct tramway plant within the same station buildings as the lighting plant, and under the same management; or, (*b*) the existing lighting machinery may be employed. The authors give curves showing that if the same plant be used for lighting and for the tramway work, a fairly steady load is obtained in the day-time, but the usual peak of the curve is largely increased.

The power required for driving the cars during the period of heavy lighting load may be obtained from accumulators. These would be charged direct from the station machinery, if suitable, or from the same motor generators which supply the cars. The authors show the result by means of a curve, and favour the use of accumulators. They are aware that cells have been carried on the cars and found unsatisfactory; but by their system the cells would only need to give an output of about 25 per cent. of the total power required.

This paper dealt with a most important subject, and elicited a very valuable discussion, but our space will not allow of its reproduction, except to say that the general opinion appeared to be that separate plant for lighting and tramway work was desirable.

Mr. E. S. Ruthven-Murray's paper, "On the Organisation of an Electricity Works Staff," was also taken.

The paper on "Electricity Works' Records," by A. B. Mountain, borough electrical engineer, Huddersfield, was taken as read, and the consideration of the various matters dealt with by the author was referred to a Committee of the Association which is about to be formed to consider various subjects in greater detail than is possible in a public meeting.

The members then inspected the fine electric lighting station of the Islington Vestry, which we described in our issue of May 29th last.

On Friday morning there was a business meeting for members only, and Mr. Wordingham, Manchester, was elected President for the next year.

The members left about 2 p.m. for Brighton, and were received at the Pavilion by the Mayor and the Electric Lighting Committee.

The paper on

Extensions to Outlying Districts

by A. H. Gibbings, Borough Electrical Engineer, Bradford, was then taken as read. It dealt with the cost of extending supply into the suburbs and houses scattered over a large area. The author gives a useful table of rentals of houses, shops, &c., in one particular street with the gas bills for each particular rental. He gives curves showing the effect of the addition of outlying district loads to the loads in the central area. The paper was followed by a good discussion. Some speakers, notably Mr. Giles, Blackburn, advocated the payment of 6 per cent. interest on the cable outlay by consumers in the outlying districts. The majority of the speakers, however, considered the cable itself as "the best canvasser," and advocated the laying of the mains without waiting for demands, believing business was certain to follow

After the meeting the members were conducted by Mr. Arthur Wright over the new electric light station. The old building was found far too small, and the present one is not yet completed, but the plant is being put in place rapidly. We shall take an opportunity of dealing with this station at a future time. One of the most interesting points is, that at Brighton the day load is taken by direct current, and at a certain hour rotary transformers are brought into operation which produce alternating current, and during the hours of heavy load this is used in place of direct current.

We can only add, in conclusion, that the meetings of the Convention of this new Association were most interesting, and we feel sure that the body will materially assist the more general use of electricity, and also the acquisition by public bodies of the means of supply.

THE NUREMBURG EXHIBITION.

(*From our Special Commissioner.*)

In 1882 The Engineer gave some account of an interesting and successful Exhibition held in Nuremburg that year. It was the first Bavarian National Exhibition, and was conducted under the auspices of the Bavarian Industrial Museum. This institution has this year entered its twenty-fifth year, and to celebrate the occasion, mindful of its previous success, determined to arrange and conduct a second Bavarian National Exhibition. To make it as representative as possible, the various provinces of Bavaria were invited to participate in the enterprise, which they did in a half-hearted sort of way; but yet in a short time the necessary guarantee fund was obtained, Nuremburg and neighbourhood contributing 1,085,000 marks, the rest of Bavaria 133,500 marks. The site selected was the beautiful Stadt Park, situated to the north-east of the town, and a penny tram ride from the centre of it; a spot familiar to all readers of "Faust." In a year and a-half the various buildings were erected; they are all timber structures, stuccoed outside, dazzling in their whiteness and pleasing in their architecture. The appearance of the main buildings may be gathered from the illustration, which shows the commercial and industrial building on the left, the three-aisled machinery hall on the right, and the transport and educational departments in the centre. The industrial and commercial building covers 31,200 square yards, the educational and transport 6960 square yards, and the machinery hall 111,600 square yards; the central aisle of the industrial is about 60ft. high, 670ft. long, and over 80ft. wide, and stretching at right angles from it are side aisles 200ft. long. Besides these there is the art gallery, covering an area of 2760 square yards, and many smaller buildings dotted here and there over the Exhibition grounds, which in all comprises an area of 194,880 square yards. Of the minor buildings, the wine house, the Nuremburg, Culmbach and Munich beer halls are prominent in the picturesque quaintness of their architecture, being reproductions of old-time buildings, and they prove very attractive for other reasons.

The general arrangement may thus be sufficiently gathered from the illustration. There are about 3000 exhibits. The main building with its side aisles is devoted to industrial products arranged territorially, each of the aisles having been allotted to one of the provinces into which Bavaria is divided politically, the decoration of each hall and arrangement of the collection having been done in each case by the particular province. This section of the Exhibition presents points of particular interest and attractiveness, and the points of difference and distinction, in so far as they interest your readers, will be referred to later on. In the educational section there is the usual display of diagrams and appliances, too many to enumerate, and none of sufficient prominence to attract during a preliminary inspection of the Exhibition. The transport department includes the postal and railway sections. The latter is perhaps the most important section in the Exhibition, as the whole range of the railway industry is included, and not alone is the present-day practice well represented by rolling stock and other appliances, but also a series of highly-finished and beautiful models and diagrams illustrate in a striking manner the development of this industry in Bavaria since the year 1844. I hope in a future letter to call attention to this unique collection, and to many other exhibits of interest in this section. What may be mentioned particularly now are electrically-worked turntables and traversing tables, compound locomotives, duplex-compound locomotives, and four-cylinder compound locomotives; whilst to the general public the panting, puffing, and gasping of a Westinghouse brake installation for fifty carriages proves an irresistible attraction.

The brewing department is a special feature. There are several plants that have a strong family likeness, so that a closer inspection only will reveal the differences between them. One, however, is worked by electricity.

The machinery hall is an imposing structure, rather marred by lack of finish; the central aisle is 500ft. long and 60ft. high. The most important exhibit in this hall is that of the Elektricitäts Actiengesellschaft, formerly Schuckert and Co., of Nuremburg. They have an excellent display of engines—vertical, horizontal, marine—and of dynamos, motors, and other electrical appliances. They, in fact, supply from their steam engines and dynamos the 2700-horse power required by the machinery in motion and various other operations conducted in this hall. Other machinery exhibits of note are those of the Maschinenfabrik Augsburg, the Dinglersche Maschinenfabrik, and others; whilst the Schmidt superheated steam compound engine, and display of pumping machinery of the Maschinen and Armaturfabrik, formerly Klein, Schanzlein, and Becker, are conspicuous. What, however, may be regarded as the characteristic features of this part of the Exhibition are various local industries in operation along the side aisles. There are twenty-three at work, and, with few exceptions, are worked by electromotors, of which, therefore, a great number of patterns and sizes can be seen working, sometimes boxed in, sometimes open, sometimes alongside the worker, sometimes hidden away in some corner, or in some out-of-the-way shelf, or under the table. The quietness, cleanness, comfort and convenience of the general introduction of electricity in small industries is most strikingly demonstrated. These portable electromotors for agricultural purposes, electrically driven saws, lathes, sausage machines, &c., further illustrate how keenly alive the Nuremburgers and their neighbours are to the capabilities of electricity, and consequently the construction of such electrical appliances has become one of the staple industries of the district.

Another industry of no small importance is the making of printing presses, of which a good number are exhibited; and, moreover, two daily papers are printed in the Exhibition. There are other machines for metal, wood, glass, stone, clay, and leather working, and for milling and agricultural purposes—the latter not important; and as is expected in connection with the large brewing industry, there are a few ice-making plants, the Linde system being to the fore. They do the freezing for theartificial ice-rink.

The Exhibition was opened on the 15th of May, and will remain open until the 15th of October. Up to the 10th of June 190,000 admission fees had been taken at the gates, and 11,000 season tickets had been issued, and this in spite of the fact that the Exhibition had not been well advertised.

The object of this Exhibition is to demonstrate the productive power of Bavaria, and as I have already indicated, this power extends over a wide and varied industrial field; and, as might be imagined, the main object of this activity is the supply of the wants of the people at home and abroad. It is achieved, not by striving to make new discoveries, but by employing discoveries already known to the best advantage, and adapting them to the varying circumstances of industry and commerce. This position of affair is well illustrated at the present Exhibition, for things of striking novelty are not to be found, but adaptations and improvements may be everywhere observed. Take, for example, the electromotors already referred to, whilst the historical collection of railway rolling stock illustrates thisstill better.

Therefore, I did not search particularly for novelty in looking round the provincial exhibits, and was not disappointed at not finding it. All provinces produce various articles of food, solid and liquid; of clothing, household utensils, some more, some to a less extent, and various sundries unnecessary to enumerate. But it may be interesting briefly to note what appears to be characteristic of each province. Upper Bavaria seems great in artistic and ornamental objects in gold, iron, leather, enamel, marble, and zinc; produces peat-moss litter, peat-moss machinery, and cement. Lower Franconia is prominent in wine and fruit; Upper Franconia in glazed tile work, cement, basket work, and textile goods, having the only exhibit of flax, also hops. Middle Franconia specialises in toys and models, iron, steel, and metal work, pencils, soap, and "Sanitas" appears in this section. Swabia makes a good exhibit of cotton spinning, wrought iron, bronze and brass work. Lower Bavaria, woodwork and all kinds of glass. Oberpfalz and Regensburg, the only mining and metallurgical exhibit worthy of note; the Bayerische Braunkohlen and Briket Gewerkschaft have built a very realistic mining gallery, showing brown coal working, and an excellent model of a lignite washing and drying plant and briquette machine. The lignite is washed free from woody fibre, dried to a specified degree, and submitted to a pressure of 1500 to 1800 atmospheres per 100 square centimetres of surface; and yields a good briquette without any admixture of tar or other cementing material. The Eisenwerkgesellschaft Maximillianshütte have a fine exhibit: wall diagrams showing their iron mines, blast furnaces, steel and rolling mills, and an excellent display of products; sections of rails, girders, angles, T's, channels at the various stages of rolling, and single girders, rails, channels, varying in other dimensions, but 170ft. long; besides sleepers, ores, &c., both work and material good. The province of Rheinpfalz is distinguished by enamelled iron utensils, wire gauges, gas and water meters. Brewing utensils and plants are frequently encountered, so too pianos and furniture, and bicycles occasionally. There are special light refreshment bars in each provincial exhibit—in some situated in picturesque representations of local scenery. In the Swabian garden there is a charming little cheese, dairy, and factory.

Lithographic stone from Solnhofen is shown, and Faber's pencils are not forgotten. The following table shows the distribution of industries in Bavaria in 1896:—

Gruppe.	Upper Bavaria.	Lower Bavaria.	Pfalz.	Upper Pfalz.	Upper Franconia.	Middle Franconia.	Lower Franconia.	Schwaben.	Total

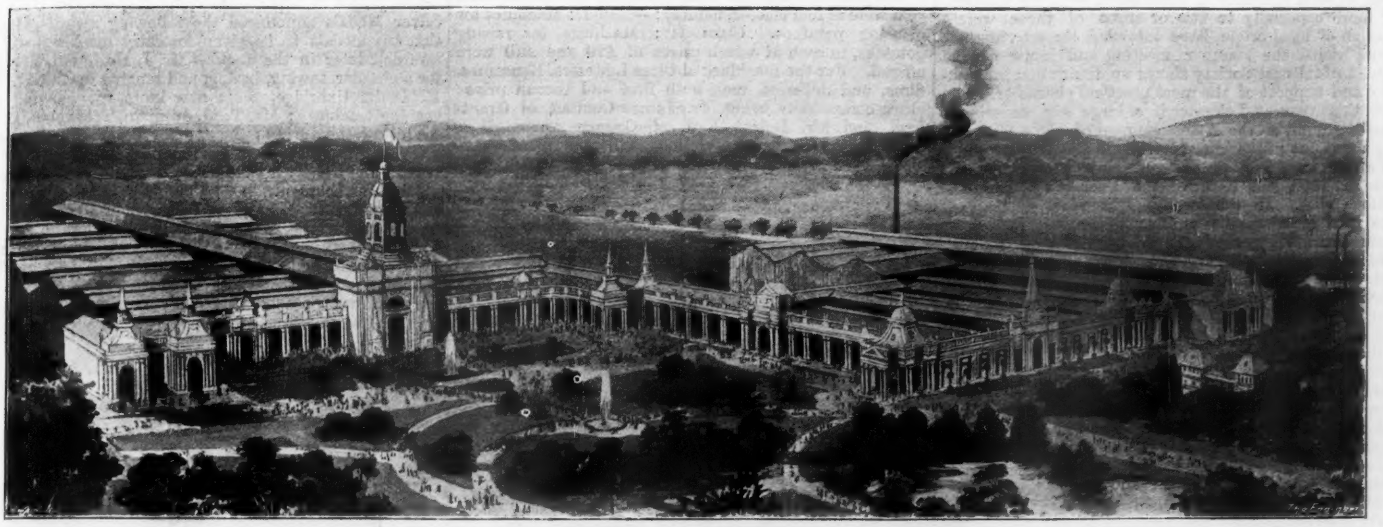
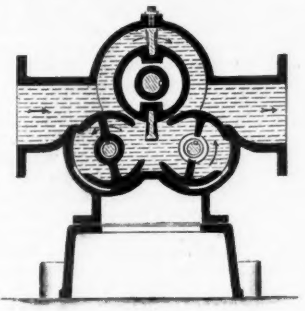
The educational section shows clearly that great importance is attached to technological instruction, and this perhaps in some way accounts for the prominent position occupied by Bavaria in so many industries. The brewing plants all consist of boilers, mashing tuns, and strainers, with the necessary pipes, pumps, and agitators, stirrers. All present a highly finished appear-

THE EXHIBITION BUILDINGS AT NUREMBURG

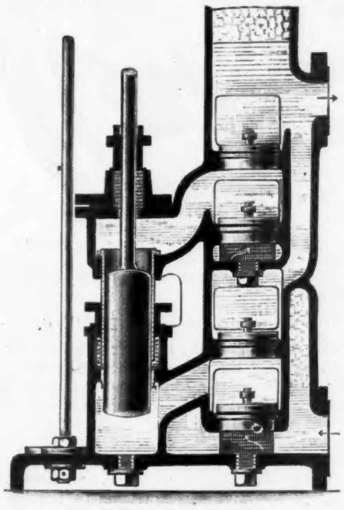


ance, and merely differ from one another in details of arrangement or mode of applying the mechanical power.

In the machinery hall there are several creditable exhibits; but perhaps an idea of this section will best be gathered by briefly stating the objects included in the chief display, that of the Elektricitäts-Actiengesellschaft, formerly Schuckert and Co., a collection of dynamos and collections of alternating motors of one, two, and three phases, various searchlights, movable and fixed, and appurtenances; a collection of reflectors in different stages of manufacture; reflectors for illuminating fountains; regulating, releasing, reversing, and safety appliances for motors, arc lamps, &c.; electric counters and measuring instruments of all kinds; complete apparatus for accumulator installations; electric lighting appliances for both arc and incandescent; lightning conductors; telegraphic appliances, &c. &c.—in all thirty different groups of exhibits, to which attention may be drawn later on. Another good exhibit is the display of pumps by the Maschinen und Armaturfabrik, formerly Klein, Schanzlin, and Becker, their main feature being the use of a single stuffing-box for plunger pumps, horizontal or vertical, packed from the outside, so that the packing can always be attended to without much inconvenience. They show a rotary pump, the character of which will be seen from the illustrations, and had a model of Pohle's air jet water-raiser; all these were working satisfactorily. The various small industries being successfully carried on round the machinery hall comprise enamelling, writing materials, india-rubber webbing, engraving, small metal articles, goldsmith's work, sewing and embroidery, lithography, making steatite gas nipples, with little electrical lathes, printing, glass painting and etching, needles, soap, and candles; whilst Jean Schoenner exhibits the making of metal automatic toys, and has an enormous penny-in-the-slot machine, measuring 30ft. long by 12ft. high, and including steamships, cranes, engineering workshops, railways to run in and out of tunnels, over bridges, and up and down inclines; aërial rope lines laden with trucks, inclined railways, boilers, engines, &c.; but I never saw it at work, although the reddened eyes and downcast look of many a child showed that the little nickel coin had disappeared down the deceptive slot.



ROTARY PUMP—See below



PLUNGER PUMP—See above

I have already referred to printing presses.

Finally, it may be noted that the travelling crane used in erecting the machinery has been converted into a passenger crane, and is worked by electricity. The steam for the machinery hall is supplied from five boilers, by as many different firms, having 780 square yards of heating surface, and worked to ten atmospheres. The Linde plant for the ice rink is worked by a 100-horse power Schmidt superheated steam engine; there is also a Linde liquid air plant. It is noteworthy that "Gradirnwerk" is very generally used for condensing.

The Bavarian Home-office exhibits drawings, plans, models, and objects, and statistical diagrams and tables in reference to Government buildings, watersheds and water-storing works, protection from fire and storms. mining matters, drainage works, and weights and measures, upon which I have not space now to comment, beyond saying that they are excellent, interesting, and instructive. The most striking exhibit of all is, however. without doubt that of the Bavarian State Railways; it includes ninety-eight exhibits, and some locomotives and carriages by the Etablissements für den Bau von Lokomotiven and the Eisenbahnwagen and the Maschinenbau Actiengesellschaft, Nuremburg. It is divided into four main sections:—(1) Railways. (2) Luding Donau-Main Canal. (3) Lake Constance Steamer Service. (4) Other show objects.

The railway matters are treated in the following order:—Two wall diagrams E relating to the *personnel* of the railway, giving numbers working, superannuated, sick, and pensioned; the second, the number of cases of old age, sickness, and accident; eleven wall diagrams, plans, and photographs of bridges, railway systems and stations: twenty exhibits of models, materials, and mechanical appliances relating to construction work of special interest; five diagrams relating to the working of the railways; the amount and the character of the traffic, whether passengers, luggage, goods, or live stock; the length, weight, and number of trains; tickets issued, time-tables, &c. The engineering department is represented by diagrams, drawings, photographs, models, and actual representations; the diagrams relate to statistics of the department and detail plans of workshops and workmen's dwellings, the drawings to new locomotives and carriages, the models are of locomotives, carriages, under-carriages, workshops, turntable—all to scale—of wheel press, gas furnace for heating, wheel for pressing of hydraulic press, Jauney coupling, transport carriage for narrow gauge, and specimens of brake installations, injectors, lamps, lubricants, and lubricating appliances, pressure gauges, telephones, whistles, sand boxes, ventilators, various batteries, and other arrangements on telegraphs, specimens of fuel, &c.; also chemical testing appliances, being the materials and means actually used, lends special significance to the exhibits. The most attractive exhibit of all is that showing the development of the rolling stock construction in Bavaria since 1844, the year of the opening of the State Railway; it is effected by sixteen models of locomotives one-tenth actual size, and thirty carriages, wagons, and trucks. It would be useless to attempt a description of all these in this notice; I shall therefore restrict myself to the earliest and latest. The earliest locomotive represented is on Stephenson's system, with centre driving wheel and four running wheels and six-wheeled tender; it was built by Maffei in Munich in 1844, cost £2320, and was taken off in 1871. The diameter of the driving wheel was 1·52 metres, the steam pressure $5\frac{1}{3}$ kilos. per square centimetre, the adhesion $6\frac{1}{10}$ ton, heating surface 46·5 square metres, total weight of locomotive and tender $23\frac{1}{2}$ tons. The last model represents a locomotive with four driving wheels and two leading wheels, built in 1895 by Krauss at a price of £3180, the driving wheels having a diameter of 1·16 metre, with adhesion of 56 tons, and a steam pressure of 12 kilos. per square centimetre.

There are exhibited, in addition, eight of the most recently constructed locomotives, and various carriages and wagons. A six-coupled express engine, compound, with four cylinders, by J. A. Maffei, of Munich, has a four-wheeled bogie in front; the high-pressure cylinders are inside, and work on the axle of the foremost driving wheels; the low-pressure cylinders are outside. There are all new arrangements for facilitating starting, stopping, controlling, &c., even to blast for sand. Another Maffei express locomotive has four driving wheels, a four-wheeled bogie and six-wheeled tender, and all accessories. A third has eight driving wheels, coupled in fours, the front four being driven by the two low-pressure cylinders, the back four by the high-pressure cylinders; all the cylinders are outside. Krauss and Co., of Munich, show a double-cylinder compound goods locomotive; the cylinders are outside, and are arranged tandem fashion, with working surfaces of high and low-pressure cylinders duly apportioned; an express locomotive with auxiliary driving gear, consisting of a one-metre wheel worked by special cylinders. In ordinary working the wheels are kept off the rails by springs, and only come into use when required for specially heavy work, starting, or up inclines for instance. The arrangement of wheels is a four-wheeled bogie in front, the auxiliary driving wheels, the main driving wheels 1·86 metre in diameter, two running wheels behind. The adhesion of the four driving wheels is 28 tons. The arrangement is regarded as very economical. Krauss and Co. have three other locomotives. In a future letter I shall possibly draw attention to the special features of the Bavarian locomotive, and refer to the other rolling-stock and the station equipment exhibited at this Exhibition. A noteworthy point in connection with the Bavarian State Railways is the technical instruction department, which from evidence adduced at the Exhibition appears to offer a very thorough course of instruction.

Departments not so well represented are those of machine tools, agricultural and mining machinery, and water-power moters, although it would seem that there should be plenty of water power.

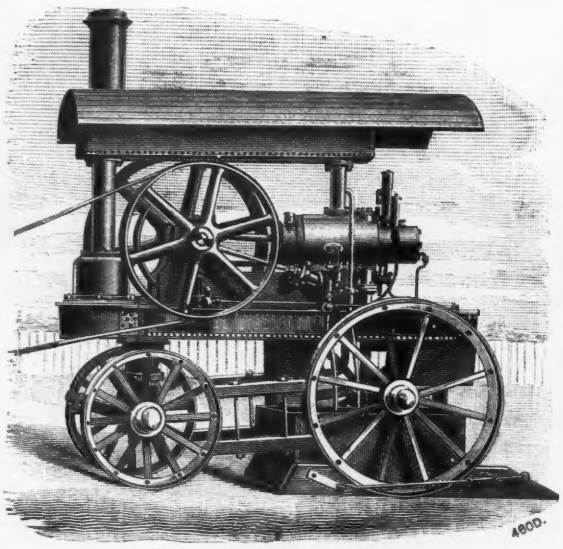
I ought not to close this notice without reference to the exhibit of the chemical town and works of the Badische Anilin und Sodafabrik, at Ludwigshafen on the Rhine. It is a very extensive exhibit, not alone of raw materials, finished products, and dyed fabrics and articles, but also of models, plans, and drawings of the whole settlement, the works, workmen's houses, hospital, &c. &c. The area controlled by the company is 960,000 square yards, of which 295,200 are covered by factory buildings, about 600 by workmen's dwellings, and more than 90 by the officials' residences; here, 30 engineers, 100 scientifically trained chemists, 230 clerks, and about 4800 workmen and others, find employment. 19,000 tons of coal are consumed yearly. There are 14,500 square yards of boiler-heating surface, and steam engine power amounting to 6500-horse power. There are private gasworks, waterworks, electrical installations, and railways and workshops, the latter covering 13,200 square yards. This is another example of what can be done by attention to efficient, systematic, thorough technological and technical training.

A word must be said for the excellent guide books, well printed, convenient in size, with headings and numbers of the rooms in bold thick type, which numbers correspond with black labels with silver figures conspicuously placed in each room. The plans, too, are very distinct, each adjacent department being of a different colour, whilst to facilitate progress through the rooms, and to avoid complicating visits an itinerary is indicated by a single red line and arrow heads.

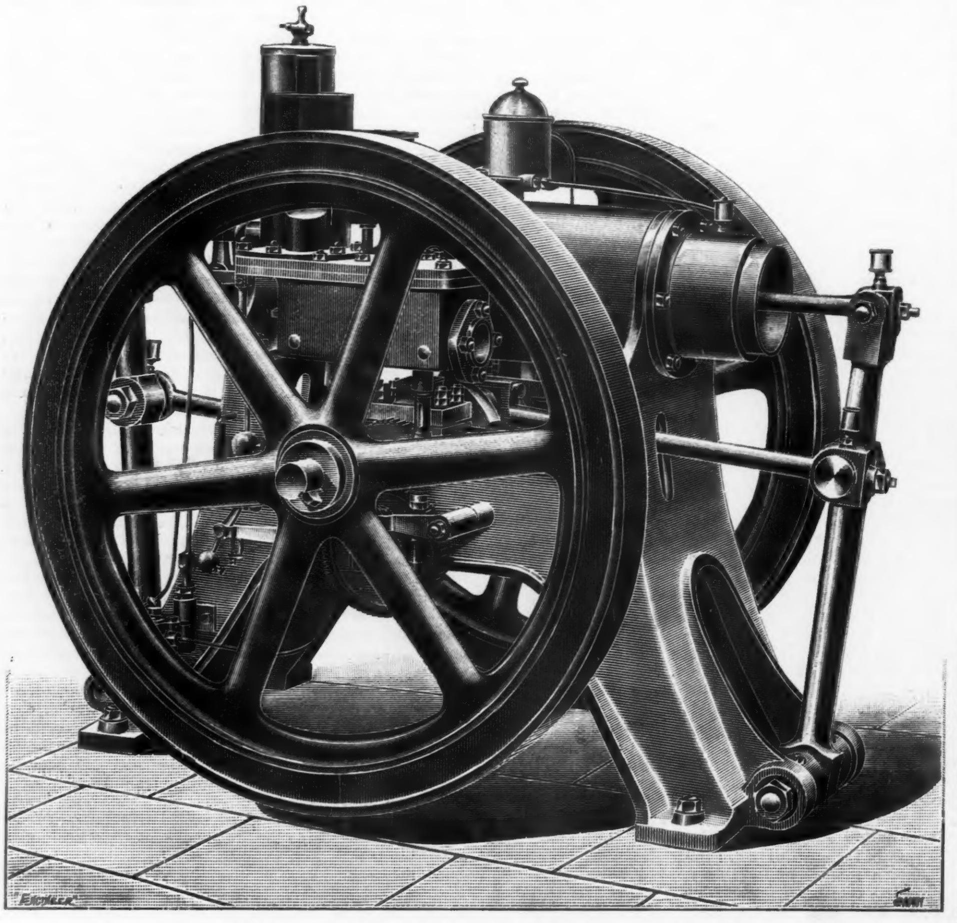
The Exhibition evidently shows that Bavaria has not only a praiseworthy past, but also a remarkably promising future, and must and will be the consumer of many materials that it has to import, iron, copper, &c., and a purchaser of many machines that it does not at present appear to make for itself in sufficient quantities, that is, if one may judge from the exhibits at the Nuremburg Exhibition, which adds a by no means insignificant attraction to the already delightful old world town.

THE ROYAL AGRICULTURAL SOCIETY'S SHOW AT LEICESTER.

Notwithstanding the growing support given by the public to local agricultural societies all over the country, and more especially to two or three of those which, although of local origin, have extended the area of their annual visits, the summer meeting and show of the Royal Agricultural Society shows no diminution in popularity and support of the most practical character. The show this year at Leicester is a large one, covering a piece of ground on the Aylestone-road of about 90 acres. It is about one mile from the Midland station, and about half a mile from Victoria Park, which was the site of the show in 1868, the date of the Society's previous visit. In the twenty-eight years since that meeting, the number of implements entered has only increased from 6369 to 6447, but the number of entries of live stock has nearly doubled, namely, from 994 to 1883. The area occupied by the implement department has, however, increased very largely, and the increase makes it by far the most important part to the Society as means of revenue, and the number of feet of shedding for implements is exactly the same as the total number used in 1868 for implements and stock together. The total length of shedding occupied at Leicester this year—including ordinary shedding, 8506ft.; machinery in motion, 2732ft.; and special shedding, 2692ft. — is 13,930ft., which is nearly 400ft. more than last year at Darlington, and over 500ft more than at Cambridge in the previous year. The special shedding includes that used for seeds, models, &c., as in previous years, but the ordinary and machinery-in-motion shedding occupies a little more space than in any year since 1889, when the Queen was president of the Windsor meeting. The most important addition is in the machinery-in-motion, which occupies nearly as much length as at the phenomenal Windsor Show, and is 264ft. more than at Cambridge in 1894, which was, with the exception of Windsor, the greatest. The growth of the implement department, the backbone of these shows, in the last few years has not been very great, probably because of the exclusion of duplicates, and because the show is already big enough, the number of things exhibited being much larger than can be seen by any visitor in the day or two at his disposal. The number of implements entered this year as new implements is not much less than last year, but the word implement is used in this list in a very wide sense, and includes a number of small interest to engineers, and only two or three of any striking novelty. The list includes such things as tidal valve interceptor, syphon interceptor tap for milk churns, spring lock and key for railway churns or milk cans, "rougher for sharpening horses," chicken brooder, and automatic vent for butter churns. On the other hand, it comprises important things, such as Cooper's new steam digger, to which a special silver medal has been awarded; a mechanically-propelled car by Messrs. Mulliners, of Birmingham; and several novelties which are not exhibited, including a similar car for merchandise, which Messrs. Howard were unable to finish in time.



CLAYTON AND SHUTTLEWORTH'S PORTABLE OIL ENGINE



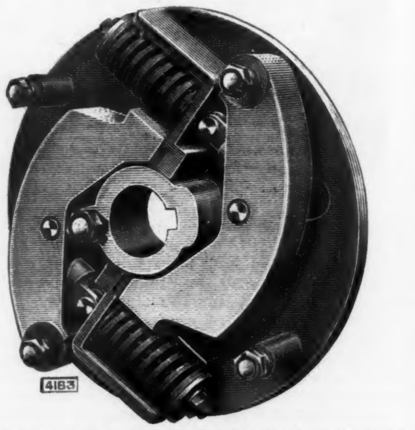
DUPLEX OIL ENGINE, BY CLARKE'S CRANK AND FORGE CO.

The prizes offered for competition by the Society this year were of four classes, namely:—Class I.: Machines for planting potatoes. Class II.: Machines for raising potatoes, in each of which prizes of £20 and £10 were offered. For the machines of Class I. Messrs. Ransomes, Sims, and Jefferies, took both first and second prize; other competitors being Mr. James Coultas, of Grantham, and Mr. Robert Kyd, of Coupar Angus, N.B. For Class II. the competitions will take place about October, in the neighbourhood of Leicester. The names of the competitors are Messrs. Coleman and Morton, Chelmsford; Messrs. John Wallace and Sons, Glasgow; Messrs. Powell Brothers and Whitaker, Wrexham; Messrs. Alexander Jack and Son, Maybole, N.B.; Messrs. Ben Reid and Co., of Aberdeen; Messrs. Woodroffe and Co., Rugeley; Messrs. Ransomes, Sims, and Jefferies, Ipswich Messrs. J. Bisset and Sons, Blairgowrie, N.B.; and the Lancashire Agricultural Implement Company, Liverpool. Class III. is of machines for gathering and sorting potatoes, the amount of prizes not being mentioned. Messrs. Keeble and Moulton are the exhibitors in this class. Class IV. is hand-power butter drying machines, for which the first prize is £5, and the second £3, the competition taking place in the dairy in the showgrounds. Messrs. R. A. Lister and Co., Derby; Thos. Bradford and Co., Salford; and the Dairy Supply Company, London, are the competitors.

The competitive trials are thus of limited interest, and for prizes of small value, as compared with those for the self-propelled vehicles next year, when the prizes will be two of £100, and two of £50.

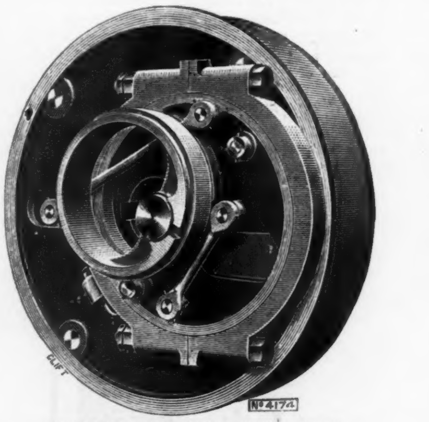
The judges of implements competing for the Society's Silver Medals announced the following awards, stating that any medals to be given for dairy machines will be awarded later in the week:—Mr. J. Hardman, Preston, for a circular sawing, boring, and tanging machine; Mr. E. Pratt, Uxbridge, for a new knife for mowing and reaping machines; Mr. T. M. Jarmain, Tetsworth, Oxon, for his swathe turner; the Cooper Steam Digging Company, for their steam digger and traction engine combined; and H. P. Saunderson, Bedford, for a mowing machine attachment.

When the Society visited Leicester in 1868, the Duke of Richmond was president. The population of the town was between eighty and ninety thousand, but now with an extended borough it approaches two hundred thousand. As the 1868 visit resulted in a profit of £488, the treasurer will probably this year return with a very large balance, which will help to make memorable Sir Walter Gilbey's year of presidency, and provide for the prizes for and cost of the trials of self-moving vehicles, which are to be held at the Society's meeting next year at Manchester. The weather during the week will, however, affect the balance for better or worse.



RANSOMES, SIMS, AND JEFFERIES' SHAFT GOVERNOR

The showyard at Leicester is conveniently situated, and the ground will be in excellent condition if moderate weather prevails. Some of it was, however, until preparations were made for this show, used as market gardens or allotments for gardening, so that although levelled, drained, and sown with grass, it is in some parts none too hard to carry heavy machinery, and would with wet weather soon be very unpleasant. The implement department is, as usual, assumed to be that which is most generally attractive, and is, therefore, arranged immediately in front of the main entrance, the royal and the members' pavilion being in the centre of the grounds, and the horses and stock surrounding at the greatest distance from the entrance, the horse ring being about 2000ft. therefrom.



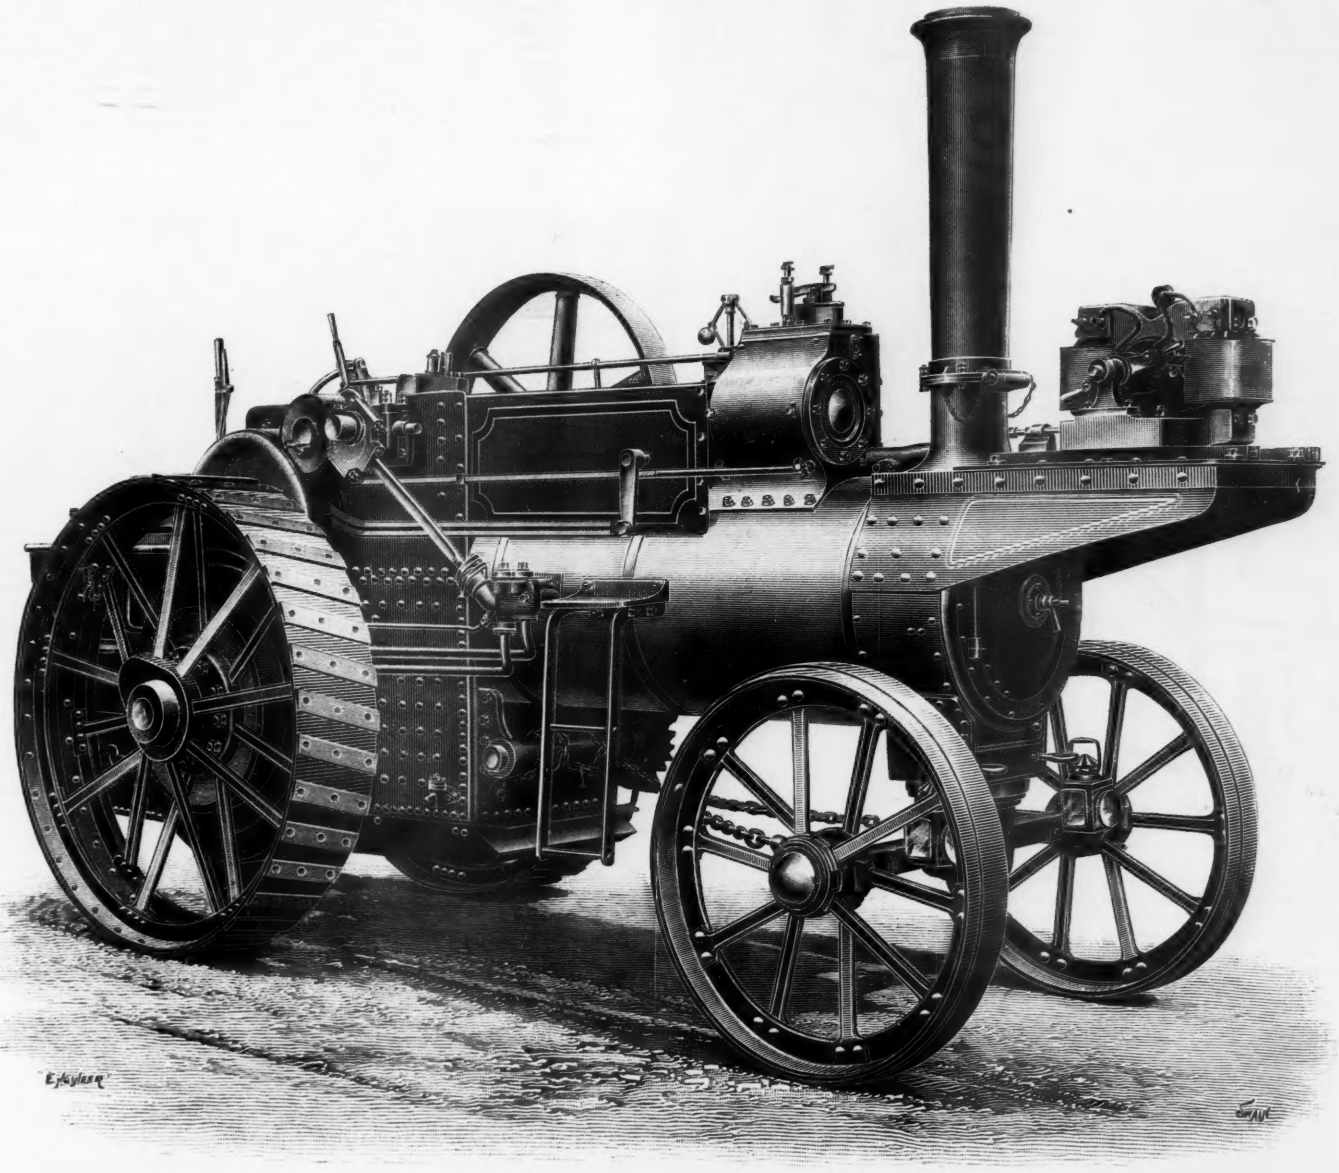
RANSOMES' GOVERNOR—INSIDE VIEW

STEAM, OIL, AND GAS ENGINES.

It is noteworthy that the number of exhibitors of gas engines is now less than the number of those exhibiting oil engines, and considering the important part taken by Messrs. Priestman Bros., of Hull, in the development of this now very popular and promising engine, it is regrettable that that firm is not exhibiting. In few cases in the invention and construction of a new machine have the labours of two or three pioneers done so much to provide competitors in their own field as in the case of the oil engine. For a good many years the development of the oil engine was quite at a standstill. The original ideas took form, but the difficulties met with in practical working were for a long time apparently insuperable. Then the problem was attacked by one or two men who were unfettered by a complete knowledge of the difficulties met with by the earlier men, but who knew something of the general design of the motor they had made. They proceeded on different lines, and were successful. They invented and they patented, and they showed others what to do, or, at least, what they had done; and what is of still more importance, what not to do. They had by this time got into a groove from which it was very difficult to

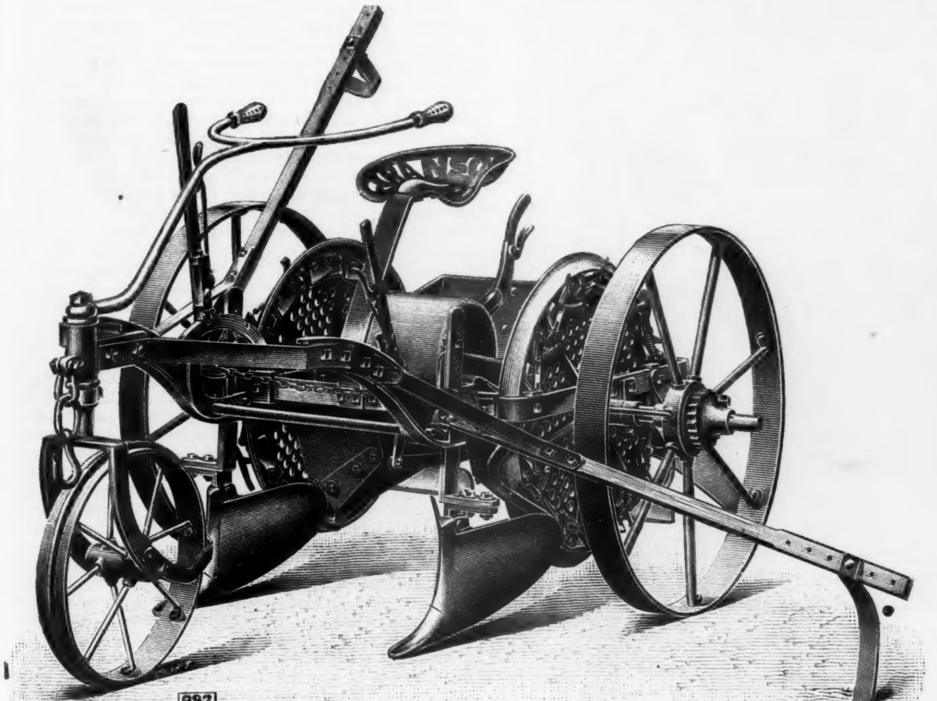
THE SHOWMAN'S ROAD LOCOMOTIVE

MESSRS. RANSOMES, SIMS, AND JEFFERIES, IPSWICH, ENGINEERS



extricate themselves; and then came a number of people who, being so far taught, found modification easy, and by using the preceding experience of others in oil and gas engines have produced the numerous forms working on similar lines, which we now see, and to some of which we shall refer.

In steam engines there are not likely to be any radical departures for agricultural work, although much higher pressures, different boilers, suitable designs for higher speeds, and for evaporator condensers, offer tempting fields for departures on lines already worked to some extent but not followed.



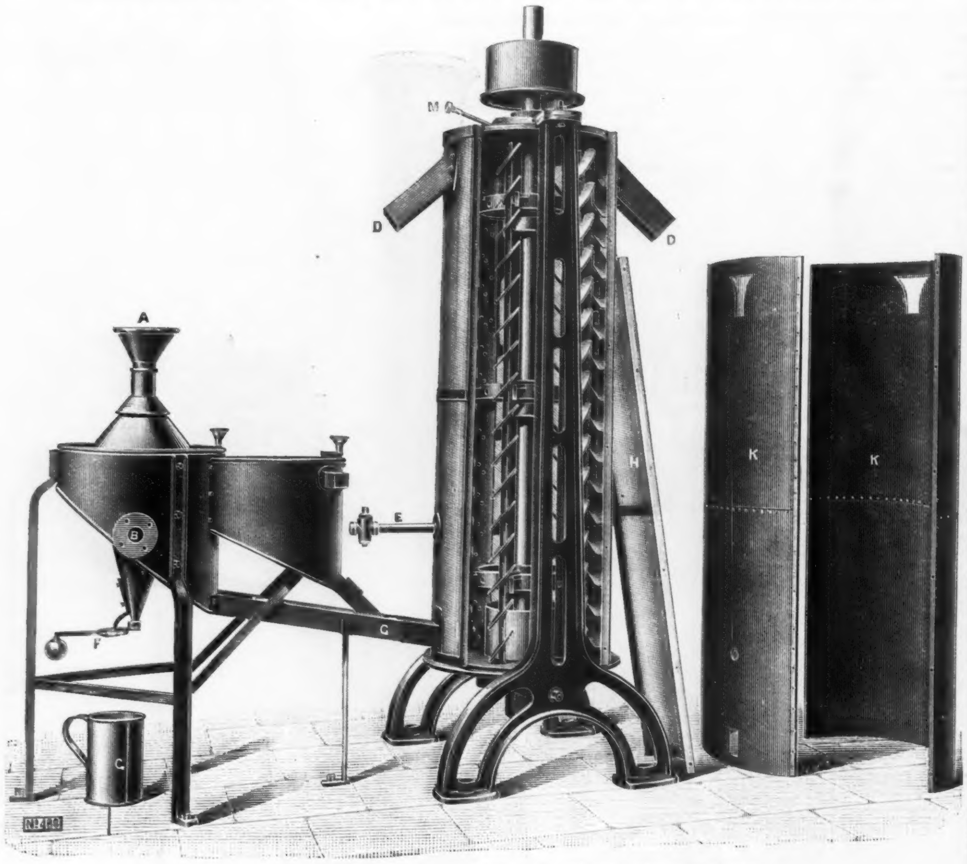
RANSOMES, SIMS, AND JEFFERIES' POTATO PLANTER

Amongst the steam engines exhibited is the vertical high-speed engine for electric lighting and other purposes, shown by Messrs. Ransomes, Sims, and Jefferies, which we shall illustrate. This firm also exhibit a road locomotive, illustrated above.

The travelling showman has secured many advantages by adopting the useful road locomotive for hauling his merry-go-rounds and numerous vans by road from town to town. The same engine is employed for placing the apparatus in position at its destination, and for lighting up the show at night. The road locomotive hauls these goods from county to county at a greater speed and at much less cost than if horses were employed. If the show vans are sent by rail, a number of horses must be hired for drawing them to the station, and for loading them on the trucks. By the possession of a traction engine, as soon as the display is over the showman can betake himself to another district without delay. Moreover, it has been proved by actual practice that there is a clear saving of time by using the road engine for this purpose, in preference even to the railway, for the moderate distances that are usually required. When travelling by road, the showman can call at small towns out of the reach of the main line of railway. The engine illustrated by Fig. 4 is one built by Messrs. Ransomes, Sims, and Jefferies, and is similar to those intended for the work described. It is mounted on buffer springs at the fire-box end, and on a plate spring at the smoke-box end. It is capable of travelling with a heavy load at four or six miles an hour. At the smoke-box end a neat platform is provided for carrying a dynamo, which is driven by a belt from the fly-wheel. The motion work of the engine is hidden by deep side plates, and the fly-wheel is also plated, so as to lessen the risk of frightening horses when travelling on the road. Mud guards are fitted over all the gearing, and the lamps are placed near the road.

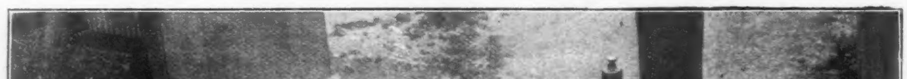
Messrs. Foden and Sons, of Sandbach, show the powerful road locomotive illustrated by the engraving on page 644. It is intended for heavy work, and is a twin compound of 10-horse power nominal. Its road wheels are 7ft. 2in. diameter on a 6in. axle, driven through their usual arrangement of gearing by a 4in. crank shaft. The cylinders are arranged as shown in the engraving, and so that high-pressure steam can be admitted to the low-pressure cylinders, both cylinders exhausting independently, thus giving the engine very great power for short periods when wanted. The engine is carried on three laminated springs, one carrying the

EXHIBITS AT THE R.A.S.E. SHOW, LEICESTER



MESSRS. E. R. and F. TURNER'S WHEAT WASHER AND WHIZZER

fore part. It weighs 17 tons, and is intended for hauling 50 tons on ordinary roads. We are informed that it hauled the two 6-horse power traction engines and the 54in. thrashing machine, also exhibited by Messrs. Foden and Sons, from Sandbach to the Show, a distance of about 80 miles, on a consumption of 14¼ cwt. of coal, or only about 20 lb. per mile. It is fitted with a steam brake, namely, a steam piston acting through levers on a hand brake on the ring of the compensating gear.



THE COOPER STEAM DIGGER—VIEW OF VALVE AND DIGGER GEAR

Messrs. Burrell and Sons, Thetford, exhibit several of their traction engines, including some showman's road locomotives, one, a very fine engine of 10-horse power nominal, being fitted with a very powerful steam brake, the long brake blocks of which act on the inside of an angle steel ring inside the large road wheels, and nearly of their diameter, the rings being turned inside. The brake blocks act on both wheels, pressed on by a 7in. piston, with a leverage of about 3 to 1, so that it is a very powerful brake, and as it acts on both wheels it holds the engine immovably on the road, not only against the fair push of a load down hill, but against the side push of a snaked train of wagons. When this brake is in use the compensating gear is, of course, rendered inoperative, so that a side-pushing down-hill load cannot make either wheel overrun under its influence. The ordinary brake applied to the compensating gear ring is also fitted to the engine, so that either or both may be used, the steam brake being mainly for heavy loads and heavy hill work, but the valve for actuating it is so conveniently situated and so easily used that no doubt the drivers will generally prefer to use it, and acquire facility in its use for slightly checking the engine and feeling their way down all hills.

Messrs. Ruston, Proctor, and Co. have a large show of their well-finished engines and thrashing machines, including a horizontal engine with a piston 17in. diameter and 32in. stroke. It is fitted with a large Porter governor which controls the expansion valve by means of a slotted link and separate excentric. Its ordinary speed is 80 revolutions per minute, and it is excellent in design and in workmanship, and the long stroke commends it for many applications. Messrs. Ruston, Proctor, and Co. are not exhibiting any of the Corliss type of engines, of which they are now building so many.

Messrs. Marshall, Sons, and Co. have an extensive collection of their engines on exhibition, some in motion, and several of their engines are also used for driving the machinery of other makers. They show one of their high-class long-stroke horizontal fixed engines with Proell's patent governor and automatic cut-off gear and Corliss exhaust valves. It has a steam jacketted cylinder 10in. diameter by 24in. stroke and is capable of from 40 to 67 indicated horse-power with 100 lb. boiler pressure. The governor is driven by a very strong silent chain running on cut toothed wheels, and formed with links which close upon the teeth as they bend round, so that there is no backlash.

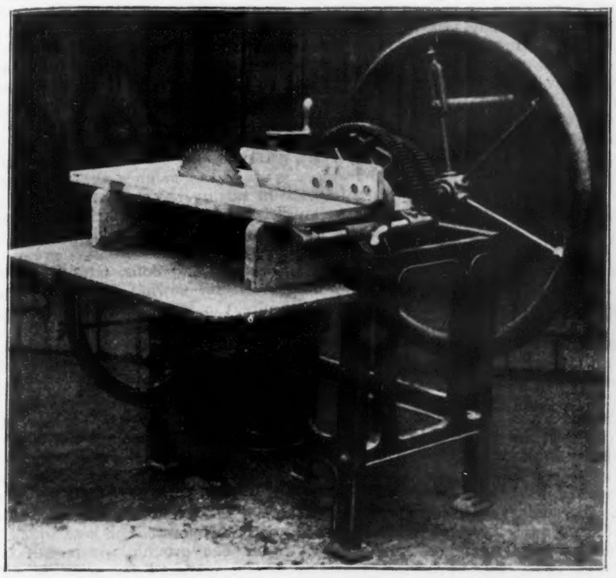
Messrs. Robey and Co. are also exhibitors of a large collection of steam engines, including an open-fronted high-speed vertical with shaft governor, oil and gas engines, and thrashing machines.

The Cooper Steam Digger Company exhibit the steam digger which is illustrated on page 644. This is the perfected form of the digger upon which Mr. T. Cooper has been engaged some years, during several of which he has been able to cultivate by digging at a profit on the digging, as compared with other modes of cultivation, and to prepare the land so well conditioned by aëration that the crops have confirmed the favourable opinion always held of land so prepared. The machine as now made effects the same end, but it is made in a more simple and stronger form in several of the details, and the wearing parts are easily removed and renewed. The tines are carried on arms mounted upon three pairs of cranks. One crank, as shown in the engravings, is driven by gearing from the engine. This crank has three pairs of throws. To these are connected the steel castings carrying the heads for the tines. The cranks are set at 120 degrees, and the frame which carries their bearings is pivoted and adjustable as to height, and the depth of the digging is determined by a pair of pads on stems which rest on the ground at the moment of the descent of the tines. The gearing drives the main crank, so that the tendency of the drive is to force the tines into the ground, and very little weight is required to enable them to enter even very hard soil. The difficulties as to the wear of the crank and other bearings have been overcome by Mr. Cooper's arrangement of dirt-excluding collars at both ends of every bearing, and breakage is prevented by making everything which is subject to heavy stress of steel and so strong that it can pull up the engine rather than break. Messrs. John Fowler and Co., are now also makers of the Cooper digger, and it is a pleasure to know that at last the Royal Agricultural Society has awarded it a special silver medal. The engraving on this page gives a good view of the valve gear from above, and of the arrangement adopted for the steering gear. The single excentric reversing gear, which we have already illustrated, is used, and works exceedingly well. The boiler is by an ingeniously arranged steam cylinder made to lift at the fore end to suit any level of the ground, and the engine is self-moving as a road locomotive for traction purposes, or for thrashing and other work.

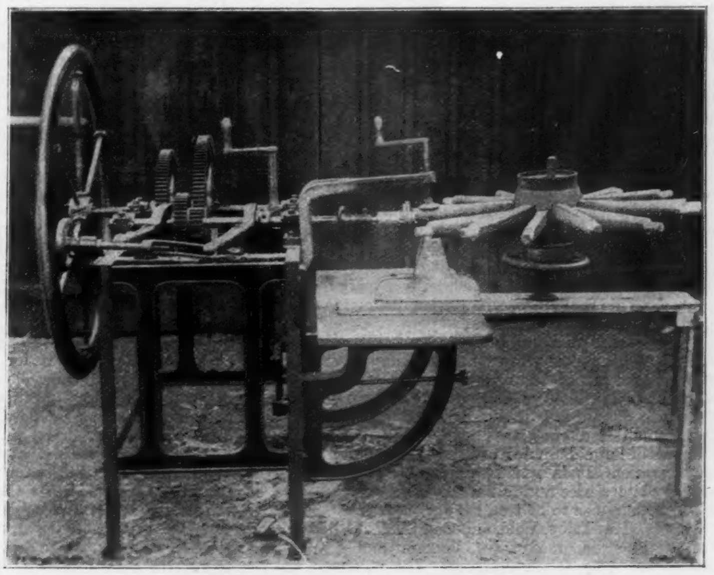
Messrs. Clayton, Shuttleworth, and Co., have, as usual, a good display of engines, fixed, portable, and traction, and in particular attention may be drawn to their Trusty oil engine, in which they have made some improvements. They have given a parallel movement to the lever which moves the oil pump and the vapour valve, and this works well, and they have modifications of the igniting apparatus, by means of which the ignition is automatically effected without either lamp or ignition tube. The engine is fitted with a rotary dashpot governor on Tyrrell and Deed's system, and the pusher finger is allowed to come into play or prevented by a lever moved by the governor, the end of which carries a roller which leaves or presses upon the pusher. The new arrangement for effecting ignition of the charge works satisfactorily, and the vaporiser exterior remains remarkably cool. We are not yet at liberty to describe this device, and must return to it on another occasion. The engine is shown driving a 6in. Hett's patent accessible centrifugal pump, and is of 7 brake horse-power, and has a piston 7·5 diameter and 14in. stroke. The valves are arranged at the bottom of the cylinder in a separate casting and can be lifted out through the top for repairs. The engine as now made in the portable form is shown by the accompanying engraving, Fig. 7, the water cooler being seen beneath the canopy which covers the engine. The cooler consists of three trays, over which the water from the jacket runs as forced up by the circulating pump. The trays are perforated with a few rows of holes, and air is drawn by the blast over the trays, so that the water is very much cooled, one charge lasting half the day. Messrs. Clayton and Shuttleworth are now the makers of the Hett centrifugal pumps, and they exhibit a 21in. pump for land drainage and irrigation, and capable of raising from 7500 to 11,250 gallons per minute according to lift.

Messrs. Robert Stephenson and Co. exhibit several of their Rocket oil engines, in which they have made some slight modifications, the chief one being in the ignition tube, which, as before, is heated with a lamp with a Swedish burner. This ignition tube is made according to Mr. Armstrong's invention, as shown in the annexed sketch. The tube T, of cast iron, is fixed by the flanges to a back projection from the cylinder, and part of the

EXHIBITS AT THE R.A.S.E. SHOW, LEICESTER

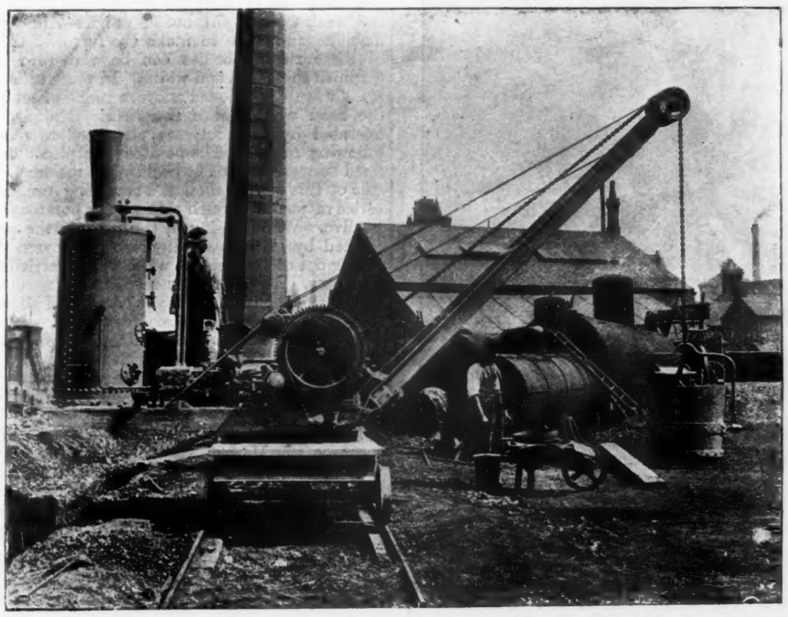


HARDMAN'S MACHINE SET FOR SAWING



HARDMAN'S MACHINE SET FOR TANGING

bottom of it has a hole made through it, and it is flattened to receive a small steel embossed plate P, fastened on by screws — not shown — with a piece of asbestos sheet between the steel inwardly embossed plate and the cast iron of the tube. A similar tube is made of steel, the thin embossed part being formed as part of the tube. The flame of the lamp plays into this "bulls'-eye," and keeps it hot enough for ignition, and very great advantages are said to arise from the use of this tube, including a not easily explainable increase in the power of the engines of 4-horse power to which it has been fitted.



TAYLOR AND HUBBARD'S STEAM CRANE

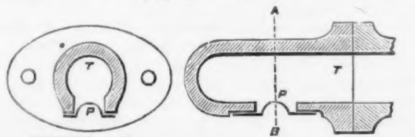


FIG 9

THE STEPHENSON-ARMSTRONG IGNITER

Messrs. Richard Hornsby and Sons exhibit a large collection of oil engines, including a portable engine with the frictionally driven pulley, which enables the work to be put on after the engine is started. Messrs. Hornsby's oil traction engine is not exhibited at Leicester, but particulars were there distributed concerning the engine, with which numerous trials have been made, including hauling loads up Spittlegate Hill. The engine is of 16 brake horse-power, weighs about 6 tons, and will, it is said, haul from 20 to 25 tons on the level, 8 to 10 tons on a gradient of 1 in 16, and 6 to 7 tons on 1 in 12. The engine is, in general appearance, much like an ordinary traction engine. Messrs. Hornsby have also made an oil tramway locomotive for narrow gauge, and of 12½ brake horse-power.

The Trusty Engine Works, Cheltenham, are exhibiting fixed and portable Weyman and Hitchcock oil engines, in which some slight modifications have been made, including the use of rotary, instead of Holt governors, for the larger sizes.

Messrs. Crossley Bros. have as usual a very large collection of gas and oil engines, and much attention was paid to the portable engine, which has received important improvements since the Cambridge trials, when it was awarded one of the Society's medals.

Tangyes Limited have also a large collection of their gas and oil engines.

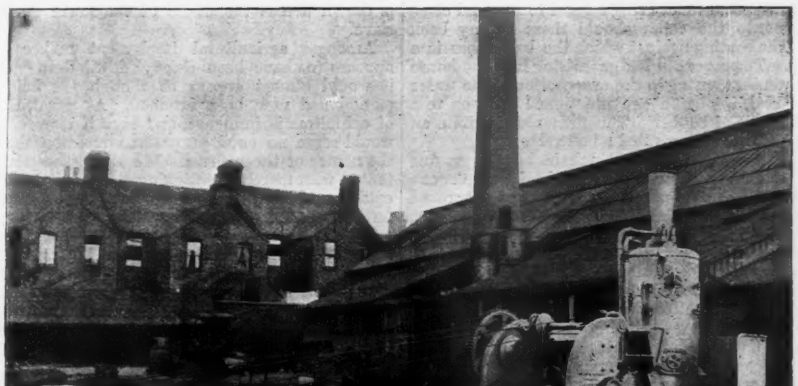
A very cheap oil engine is exhibited in two small sizes by Messrs. Carson and Toone, of Warminster, and the National Gas Engine Company, of Ashton-under-Lyne, show one with their gas engines.

Messrs. Fielding and Platt exhibit some of their oil engines at work, and almost precisely like those of which we have previously given particulars.

The Clarke's Crank and Forge Co., Lincoln, exhibit several oil engines made under Beverley's and Roots' patents, the Beverley arrangement of duplex balanced two crank engine being illustrated by the accompanying engraving. The charge is compressed and ignited between the two pistons, which move in opposite direction, actuating the rocking levers seen at either end of the engine, page 640, and from them by connecting-rods pivoted at about one-third of the length of the rocking arms from the top. The engine is compact, as shown by reference to the fly-wheels in the illustration. The pistons are 7in. diameter, and the combined strokes 15in. and the brake horse-power is stated to be about four.

MISCELLANEOUS EXHIBITS.

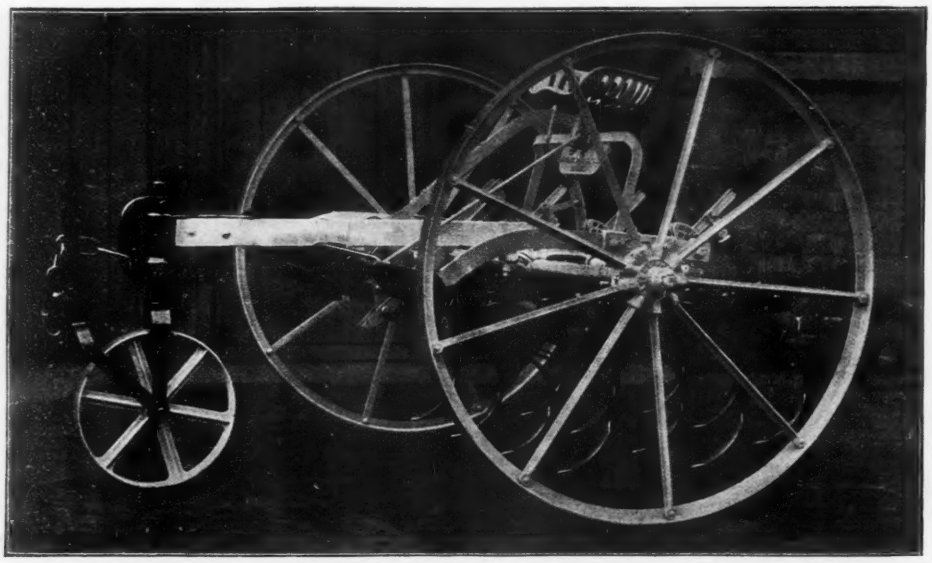
The illustrations herewith represent a steam crane with the jib in different positions, made by Messrs. Taylor and Hubbard, Kent-street Works, Leicester, which comprises several valuable features. It is designed to handle loads of one ton, and will haul on the level a train weighing 14 tons. Steel has been almost exclusively employed in the construction, and the travelling is effected by bevel gearing. As will be seen the jib can be lowered into a horizontal position for inspection and oiling without being supported from the ground, while it can be again raised to its maximum height in about twelve seconds. The boiler, of steel, is constructed for a pressure of 70 lb., and is provided with a feed pump worked from the piston-rod crosshead. The crane will slew a complete circle in seven seconds, or more than eight turns a minute, but it can be regulated to slew steadily and evenly as slowly as desired. It will derrick easily with the full load suspended, and will remain in any position. Special attention has been given to facilitate the erection and taking to pieces with-



TAYLOR AND HUBBARD'S CRANE, WITH JIB LOWERED out necessitating the employment of skilled labour, and crane users will appreciate the fact that all parts are made on the interchangeable system, so that a stoppage due to the breakdown of any part need only be of very short duration.

A useful and inexpensive tool for wheelwrights in a small way of business is that exhibited by Mr. Hardman, Adelphi-street, Preston. This machine, which is shown on page 641, is a hand-power circular sawing, boring, drilling, and spoke-tanging machine. The last-named function is probably the most important from a labour-saving point of view, and it is stated that the spokes of a pair of light cart wheels can be treated in less than half an hour. Separate rise and fall tables, easily removable, are provided for the different operations, and the gear is arranged for two speeds. The machine might be rendered still more serviceable if a chuck were provided for boring and turning up hubs, while, without necessitating a great increase of cost, the wooden table might with advantage be replaced by something giving greater rigidity. This tool has been awarded one of the Agricultural Society's silver medals.

Messrs. Isaac Hill and Son, Derby, exhibit some very useful machine tools shown in operation. Perhaps the most interesting of these is the automatic circular saw sharpener; this is a useful and efficient labour-saving tool where hot or cold saws are used. It it applicable for saws of the smallest diameter as used for brass work, and also for saws of large diameter as used in iron and steel and other works. It is readily adjustable to any pitch of tooth, while a rise-and-fall work table enables saws of wide range in size to be treated.



NICHOLSON'S SPRING STEEL TINE CULTIVATOR

Messrs. Hawksley, Wild, and Co., Sheffield, had a good show of boilers, feed-water heaters and filters, and specimens of hydraulic flanging. The "flanged flued" boiler of which this firm are the makers is made to withstand the high pressures now so much in use. In the feed-water heater perfect freedom is allowed for the expansion of the tubes, and the general construction is such that the whole can be taken to pieces by unskilled labour and cleaned easily and quickly. Messrs. G. and F. Couzens, 14, Tudor-road, Cardiff, show for the first time a newly patented device for preventing the flooding of basements or cellars by storm water or tidal causes. This is called a ball trap gulley, and is manufactured by Mr. Henry Dennis, Ruabon. The action of the trap is automatic, a floating brass ball being caused to rise and close the opening into the cellar should there be any back pressure. The seating against which the ball closes is a rubber ring. To prevent sewer gas arising into the house during dry weather, owing to the evaporation of the water making the seal, the ball above mentioned falls on to a lower seating also of rubber. This firm also exhibits an interceptor in which is provided a ball valve.

Messrs. W. and T. Avery, Birmingham, have a very fine display of weighing machines and weighbridges. On one of the latter there is provided a new and improved printing device for recording weights by means of a tape, instead of using tickets. Messrs. Christy and Norris, Chelmsford, are represented by grinding machinery, to which we referred in connection with the Bath and West of England Show. Messrs. E. and H. Bentall and Co., Heybridge, Essex, exhibit amongst a very large display of implements, a new grinding mill. These machines have flat grinding plates of larger diameter than usual, which are reversible, giving double grinding surface, and with these plates are combined conoidal cracking plates. The process of reversing requires no skilled labour, and only occupies a few minutes. The driving pulleys are arranged to run either inside the frame of the machine or on the end of the shaft. On the larger machines the feed is effected by a worm.

Messrs. E. R. and F. Turner, Ipswich, have a more than usually interesting group of exhibits, including a patented "concentric" wheat washing and stoning machine combined with a vertical whizzer. This appliance is shown by engraving on page 640. The principal parts of the washer and stoner are: A feed hopper, with adjustable distributing pipe and cone; a central vessel in the shape of an inverted cone; an annular V-shaped channel formed between the edges of the two cones; and two tanks. Water enters the central vessel by means of a pipe, and filling this vessel, passes upwards through the open bottom of the annular channel. The wheat, falling from the distributing cone, strikes the water and is carried with it over the edge of the channel into the first tank, stones and other matters of greater specific gravity than the wheat falling through the open bottom of the channel into the central vessel, whence they are removed through a valve. In the first tank the heaviest wheat sinks to the bottom, which being inclined as shown, delivers the grain to a discharge spout. The remainder of the grain is carried with the water through suitable openings into the second tank, where a further deposit takes place of all tolerably sound grain. The bottom of this tank slopes like the first, and delivers the grain in a similar manner. Hollow grains, chaff, and other light matter, float away with the waste water overflow, an arrangement being made to prevent sound grain so escaping.

The whizzer recommended to follow the "concentric" washer is a vertical machine of improved construction, shown on the right-hand side of the engraving. The inlet for wheat is at the bottom, and the outlet near the top. Superfluous moisture is said to be effectually removed without damage to the grain, and delivery is made at a convenient height for falling to an elevator. The washer and whizzer may be placed side by side, and the one will deliver to the other without any draining worm or elevator interposed between. The following is a key to the reference letters on the engraving:—A, inlet for wheat; B, inlet for water; C, spout leading from washer to whizzer; D D, outlet for wheat from whizzer; E, inlet for fresh water to rinse the wheat, required only when the water is returned for re-use in the washer; F, weighted valve which opens when a sufficient quantity of stones, mud, &c., have collected in the hopper; G, can to receive stones, mud, &c.; H, perforated cover, taken off to show the interior of the whizzer; K, sheet iron covers for the whizzer to prevent the water being thrown about; M, cup and pipe for lubricating the top bearing of the whizzer. Another interesting exhibit of Messrs. Turner's is a "vibromotor" scalper and sifter with two sieves, each 5ft. long by 3ft. wide. In this apparatus a novel arrangement of brushes is provided below the sieves for cleansing them. At either end of each sieve is an iron ring resting on lugs, but free to revolve by the gyratory movement of the apparatus. Each pair of rings is connected by a brush, so that as they revolve the brush is drawn across the whole of the lower surface of the sieve.

Amongst agricultural implement makers attention appears to have been chiefly devoted to details, and it would almost appear as though the height of perfection had now been attained. As usual, the number of exhibitors is immense, and even if it were possible it would serve no good purpose to mention the whole of the names of these firms. We shall, therefore, be contented with merely mentioning a few of the most novel exhibits which attracted our attention. One of the foremost of these was the "Hercules" spring steel-tine cultivator with reversible points. A description of one form of this appliance will be better followed by reference to the illustration, above. In the "Hercules" cultivators, the tines are mounted in groups upon separate frames, each jointed to the main frame of the machine in such a way that it can be individually and instantly lowered or raised to suit the inequalities of the land, and the exact amount of pressure applied which the state of the soil demands. The mechanism for effecting this is simple, and it has the advantage of allowing the amount of an adjustment to be accurately gauged and quickly varied. It consists of a hand lever with a spiral spring upon a connecting-rod, and a quadrant, pierced with a series of holes, to receive a cotter pin, which retains the hand lever at any angle. The tension of the springs can be relaxed or increased at will by simply turning a slotted ferrule on the connecting-rods. Thus the tines are made automatically to conform to uneven ground, and a constant pressure is maintained upon them, even should they drop into a hole or furrow. The main frame is raised or lowered as a whole and locked in any desired position by a main lever, fixed conveniently to the driver's hand, on the lifting axle of the machine. It acts on the frame through a slotted regulating link, furnished with an index marked "deep," "medium," and "light." The general depth of cultivating or working being determined, the regulator is set to correspond. Minor adjustments are readily made by means of the mechanism attached to the separate tine carrier frames above described. By use of the same main lever the tines can be raised off the ground for travelling, clearance, and turning. An adjustment at the back of the pole or shafts allows more or less lead to be given to the front tines. These machines can be supplied with single shafts and hooks for three horses abreast, or with pole and whippletrees for two or three horses, or with front swivel or castor wheel, as shown. It will be observed that the spring seat for the driver is pivoted in such a way that the driver's weight is utilised to balance the tine carrier frames, and to assist in raising them when required for adjustment, turning at the headland, travelling, or clearance. These cultivators are made by Messrs. W. N. Nicholson and Sons, Newark.

Messrs. Richard Hornsby and Sons, Grantham, also exhibit a new implement for sowing corn, clover, and grass seeds and manure, the latter being delivered into the same tubes as the seeds. It is a kind of twin drill with two boxes, in one of which the manure is broken up before being sown. Messrs. Hornsby's stand also comprises all conceivable kinds of implements for agricultural purposes.

Messrs. Ransomes, Sims, and Jefferies, Ipswich, have as usual a very effective display of implements, amongst which are the potato diggers with which they have carried off the first and second prizes offered by the Royal Agricultural Society. The first prize-winner is illustrated by engraving, page 639. The single and double-row planters can either be used for setting potatoes on land which has been ridged up, or on flat ground which has been previously ploughed and prepared for planting. For ridge work the furrows are previously prepared by a plough, and manure is deposited in them. The horses walk in the furrows, and the road wheel tires, which are of a concave form, run on the top of the ridges. In place of the single wheel shown in the cut, steel disc press wheels are used, which press the manure down, and prepare a suitable place for the potatoes to fall into. For flat work two ridging bodies are fixed in front of the machine, and serve to make the furrows. The position of these ridging bodies can be varied to increase or diminish the depth and width. In place of the steel disc press wheels mentioned above, a single wheel is used, and the road wheels have flat tires. Markers which are operated by the foot, are also used to mark out the following furrow. The potatoes are placed in a hopper, fixed between the road wheels of the machine. On either side of this hopper there is a revolving disc, fitted with a series of pockets, which take up the potatoes as the discs revolve. While resting in the pockets the potatoes are pierced by suitable needles, which prevent them from falling out of the pockets while being carried round with the discs. At the proper moment the needles are withdrawn and the potatoes are released, and allowed to drop into the furrows. The road wheels are adjustable to admit of planting potatoes in rows from 24in. to 30in. apart, and suitable change wheels are provided with every machine, by means of which the potatoes can be planted at distances of 12in., 14in., and 16in. apart in the rows, at pleasure.

Mr. T. M. Jarmain, of Tetsworth, Oxon, exhibits a new machine, the Haseley swathe turner, which, we are informed, has been successfully tested in light and heavy crops of clover and grass. This implement is constructed with a wrought iron frame on the same principle as the well-known Haseley tedder. It has two steel spring drums driven by an endless chain, which effectually turns over two swathes at one time, exposing what was the under part of the swathe to the sun and atmosphere, thereby facilitating the drying of the crop. The machine is well balanced, the draught is exceedingly light, and the gearing is entirely under the control of the driver when in his seat. The levers are close to his hand, whereby he can instantly start and stop the machine and regulate the height of the drums from the ground. The maker claims that a lad and cob with this machine will turn from four to five acres of grass per hour. The drums can be adjusted to suit the different widths of cut of mowers.

Mr. J. Roots, of East Dereham, Norfolk, is showing for the first time a convertible hay and straw press, weighing only about 7 cwt., which is inexpensive and can be worked by one man. The press is fitted with a main lever, to which is attached the top table, which is pivoted to allow it to tilt to meet the unevenness of the truss. After the main lever is brought into position, it has a main rack and pinion attached, by which the needed pressure can be instantly applied. When the truss is sufficiently pressed and tied, a catch is liberated, and the press is instantly relieved and ready for another truss. When used for straw, the top table is removed, and straw attachments are then placed into position to receive the material in its loose state. When the cradle is filled, the pressure is applied the same as for hay; the straw is then tied, the catch liberated, and the press is instantly relieved ready for refilling.

Another new implement is an adjustable self-cleaning flat corn screen—Cousins and Weathehoff's patent—made by Messrs. Penney and Co., Lincoln. It has the advantage of being very simple, and is said to be adaptable for dressing and separating corn and all kinds of cereals. This machine is fitted with an adjustable screening bed, the meshes of which can be opened to suit the largest barley or wheat by the simple turning of a hand screw, which may be done whilst the machine is in motion; or, by turning in the opposite direction, it can be closed fine enough to dress the smallest sample of wheat, barley, and other cereals.

Messrs. J. and F. Howard, Bedford, exhibit a spring steel tined cultivator, in which the tines are mounted on the through axle of the travelling wheels. They have thus an angular motion, and readily clear themselves of weeds and rubbish when raised.

RAILWAY MATTERS.

Writing in a railway carriage moving at high speed is now rendered possible through suspending a light desk from the roof by elastic bands, and the results have been so satisfactory that these desks are to be adopted generally on German lines, a small fee being charged for their use.

Mr. Eric G. Barker, Locomotive Superintendent of the Wirral Railway, Birkenhead, has designed, and Messrs. Beyer, Peacock and Co., have just completed a twelve-wheeled tank engine, No. 11, for that line. It has a leading bogie, four coupled wheels of 5ft. 2in. diameter, and a trailing bogie; cylinders, placed inside, 17 by 24; total weight, 59 tons 16 cwt. 1 qr. The double-bogie arrangement is found to give very satisfactory results. Boiler pressure 160 lb. per square inch.

The Second Soudan Battalion has been ordered to assist the Railway Battalion in carrying the extension line over the difficult river level at a point six miles beyond Ferket. It is now a matter of speculation whether the steamers at present at Wady Halfa or the Ferket Railway will be the first to reach Kosheh. That place is, however, being prepared for the advent of both. The end fort will probably be made the terminus of the line, and the other buildings be used as workshops and coal yards. Sites for quays and docks have already been assigned.

The London, Chatham, and Dover Railway Company announce that the night mail service from London to the Continent, *viâ* Dover and Calais, will, on and from July 1st, be accelerated by 45 minutes, and leave Victoria and Holborn at 9.0 p.m., arriving in Paris and Brussels, &c., at the same time as now. The company's fast new paddle steamers, Dover or Calais, have now replaced the smaller boats in this service. In connection with the above alterations there will be an appreciable acceleration of the P. and O. Indian mail service on Fridays. Passengers leaving Victoria at 9.0 p.m. will arrive at Brindisi at 6.20 p.m. on Sunday evening, an acceleration of over two hours.

At the summer meeting of the Institute of British Carriage Manufacturers, held in the Mansion House, Mr. J. Philipson, proposed that a letter should be forwarded to the directors of the North-Eastern Railway Company, calling attention to the injury Stephenson's historic engine, "Puffing Billy," was sustaining by being left at the end of the High Level Bridge exposed to the effects of the atmosphere at Newcastle. Mr. Hooper, in seconding the motion, said there were three historic engines. The first was carefully preserved at South Kensington, the second was cared for at Darlington, but the third was exposed at Newcastle to the effects of an atmosphere often laden with smoke and rain. He thought the sending of the letter would result in steps being taken to preserve Puffing Billy. The resolution was unanimously passed.

In order to determine the highest possible speed that may be attained on railways, trial runs were lately made between Berlin and Lübbenau on the Berlin and Görlitz line, states the *Rheinische Westphälische Zeitung*; and for these runs a special express engine of new design with four cylinders and driving wheels of 2 metres (6ft. 6in.) diameter has been constructed, thus giving the engine a much greater height above the rails than usual. For these runs the composition of the trains was very various, amounting sometimes to 100 axles. With a train of 30 axles the highest performance, viz., 106 kiloms. (65¾ miles) per hour was recorded, being 20 kiloms. (12 miles) more than the highest speed hitherto attained by the quickest German lightning train (Blitzzüge), viz., the Berlin Hamburg D-Zug, which runs through a distance of 286 kiloms. (177½ miles) in 3½ hours, while the speed of ordinary German expresses is only 70 kiloms. (43½ miles) per hour. Not any of the runs have hitherto been accompanied by accident, although the trains have run past all the intermediate stations without slackening speed. The portions of lines chosen for these runs have been tolerably horizontal over their whole length, and have very few curves.

A report from our Consul at Lorenzo Marquez, which has just been published, shows that the lack of adequate landing facilities at the port causes serious inconvenience to trade with the Transvaal, and is driving vessels to the Natal ports from Delagoa Bay. The steamers of the New Zealand Karri wood trade, for the mines on the Rand, are said to have decided to try Durban on account of the prolonged delays either at Delagoa Bay itself or on the railway up to the Transvaal, and many other vessels are mentioned by the Consul as having left Delagoa Bay to discharge elsewhere. Within a few days of the date of the report—March 6th—the British barque Shakespeare, with 1400 tons of Oregon pine consigned to Delagoa Bay, sailed from East London without breaking bulk, as it was useless to attempt to discharge her in reasonable time at Lorenzo Marquez. Another ship, the Blairgowrie, with 2300 tons of timber, was ordered by her consignee in Johannesburg to leave for Durban to discharge her cargo. The master of a British steamer, with 4000 to 5000 tons of railway material, lodged a complaint at the Consulate that, although he arrived at the port on February 11th, the work of unloading commenced only on the 24th, when but 20 tons were discharged, and then ceased altogether. As to the Delagoa Bay Railway, Mr. Casement observes that there is a perceptible need of ballasting at more than one point, and the engines do not appear to receive the careful handling necessary to their maintenance in an efficient state. But since their seizure of the line the Portuguese have made many improvements. The total receipts of the line last year amounted to £80,418, and the tonnage of goods carried to 88,276 tons. The profit of the line for the year was £33,690.

Lieutenant-Colonel H. A. Yorke, R.E., has reported to the Board of Trade on the accident that occurred on May 6th, near Banavie Junction, on the West Highland—North British—Railway. As the 7.35 a.m. passenger train from Glasgow to Fort William was running round the curve between Spean Bridge and Banavie Junction on that day the whole of the train, with the exception of the engine, left the rails and ran along the ballast for 115 yards before it came to rest. The permanent way had three rails bent, and 120 sleepers and 115 chairs more or less destroyed. Lieutenant-Colonel Yorke says he has no hesitation in attributing this accident, which by rare good fortune was unattended by any personal injuries, to the expansion and consequent distortion of the line produced by the great heat prevalent on the day of the occurrence. During the forenoon of May 6th the temperature registered at Fort William, by a thermometer placed in the sun 2ft. above the grass, was 128 deg. The accident happened at 12.38 p.m., when, the railway at the spot being entirely devoid of shade, the rails were exposed to the full glare of the sun. Driver Thornton says that when he was passing the 97¼ mile post he saw that the line a short distance in front of him was distorted to the left to such an extent that he anticipated that the train would leave the rails. He promptly applied the Westinghouse brake, and almost immediately after this the tender and vehicles composing the train left the rails towards the inside of the curve. Inspector Campbell had travelled over the line early that morning in the van of a ballast train, and noticed nothing wrong with it. The fact that the engine did not leave the rails, although the rest of the train did, may probably be attributed to the flexibility imparted to the engine by the leading bogie, which was able to adjust itself to the irregular curvature of the line produced by the expansion of the rails, whereas the tender, with its six wheels and rigid wheelbase, was most probably the first vehicle to leave the metals, and dragged the rest of the train after it. The mishap must be regarded as purely accidental, and there is no evidence to prove that any blame attaches to any servant of the company in connection with it. There are, however, the report adds, some indications that this portion of the line has not been maintained in a thoroughly first-class condition.

NOTES AND MEMORANDA.

The rainfall at Greenwich for the year ending 1896, April 30th, was 19·76in., being 4·78 below the fifty years' average. This is the smallest rainfall since the year 1884-85.

In a paper in the *Comptes Rendus* "On Molybdenite and the Preparation of Molybdenum," by MM. Guichard, it is stated that metallic molybdenum free from sulphur can be obtained by subjecting the mineral molybdenite in a carbon tube to the electric furnace—900 ampères, at 50 volts—for five minutes. The ingot contained about 92 per cent. of molybdenum, 2 per cent. of iron, and 7 per cent. of carbon.

New experiments on the distribution of velocities in tubes have been described by M. Bazin. No single expression can be given which will accurately represent the velocity of an air current at any point between the centre and circumference of the tube, the law being very complicated. At a distance from the centre equal to three-fourths of the radius of the tube the velocity was equal to the mean for the whole tube.

A recently issued number of the *Alembic Club Reprints*, published by Messrs. W. F. Clay, contains Faraday's papers on "The Liquefaction of Gases," 1823-1845, and an appendix consisting of papers by Thomas Northmore on the compression of gases, which were referred to by Faraday, in his historical statement in the following terms:—"The most remarkable and direct experiments I have yet met with in the course of my search after such as were connected with the condensation of gases into liquids, are a series made by Mr. Northmore in the years 1805-6." Students of physics, and every one interested in the subject of the liquefaction of gas, should, *Nature* says, possess a copy of this latest addition to the *Alembic Club Reprints*.

In a paper on the "Action of Acetylene upon Iron, Nickel, and Cobalt reduced to Hydrogen," by MM. H. Moissan and Ch. Moureu, it is stated that if acetylene, which has been allowed to suddenly impinge upon pyrophoric iron which has been reduced by hydrogen at the lowest possible temperature, the gas is decomposed with incandescence into its constituents. At the same time, owing to the high temperature, condensation takes place, and a liquid hydrocarbon, rich in benzene, is produced. The same phenomenon is produced by pyrophoric nickel and cobalt, and also by platinum black. No compound containing metal can be isolated, and the decomposition appears to be due to physical causes.

E. W. Parker, Statistician of the United States Geological Survey, has completed the compilation of the statistics of coal production in the United States during the calendar year 1895. The total output from all mines was 171,804,742 long tons, or 192,421,311 short tons, having a total value at the mines of 197,572,477 dols. The output of anthracite coal in Pennsylvania increased from 46,358,144 long tons in 1894, to 51,785,122 long tons in 1895, a gain of over 5.400,000 tons. The product of bituminous coal increased from 118,820,405 short tons in 1894, to 134,421,974 short tons in 1895. There was an increased production in all but five of the twenty-nine coal-producing States. The States in which a decreased product was shown were Georgia, Kansas, North Dakota, West Virginia and Wyoming. The principal loser was Kansas. The product among the other leading coal States was:—Illinois, 17,735,864, value £2,847,831; Ohio, 13,376,137, value £2,127,511; and West Virginia, 11,424,863, value £1,557,424.

Some rules are given in the *Aluminium World* for obtaining the best casting with aluminium bronze, in order to avoid the difficulties which are so frequently met with in melting. An essential point mentioned is the special care to be taken not to overheat the metal, the fact being that, if it be heated to too high a temperature, the aluminium will oxidise, the oxide which is thus formed making the entire casting what artisans term "dirty," and the metal will also be spongy from the presence of large amounts of occluded gases; the scum, too, which floats on top of the melted bronze in the crucible must be prevented from going into the body of the casting, this being practicable by providing the casting with suitable skim gates. The greatest trouble in making a bronze casting, however, arises from the shrinkage of the metal—which is very great—a difficulty which is overcome if the casting have a large sinking head and "risers," it being necessary, however, in many cases to make the sinking head fully as large as the casting.

The number of applications for British patents during the year 1895 was 25,065, this being a diminution of 321 on the number of applications for last year. This is so far remarkable, as it is practically the first year since the Patent Act of 1883 in which the number of applications has not shown an increase. In 1884, the first year under the new regulations, there was a larger number—17,110—than in 1885—16,101—but this is accounted for by the fact that a great number were held back in order that the applicants might take advantage of the reduced fees introduced by the Act. From 1885 to 1894 the increase was continuous. The highest number under the previous law was 6241 in 1882. It is mentioned in one of the appendixes that the total number of patents for inventions granted between 1617 and 1852, in which year what may be termed the first Patent Reform Act was passed, was 13,561, just about half the number now applied for in a single year. The Comptroller's report points out that the decrease of last year was only in applications accompanied by provisional specifications. From this it may be concluded that applicants find that the method of proceeding by provisional specification is less really advantageous than that of filing a complete specification at once. The total receipts for the year amount to the large sum of £187,012; the expenditure amounts to £100,671, leaving a surplus of £86,341. It should be mentioned that over £10,000 of the expenditure was in connection with the new buildings of the office.

A lecture on acetylene gas was lately given at Liége by Professor Raoul Pictet, of Geneva, in the course of which he lighted two candelabra each with nine burners, consuming together 270 litres = 9½ cubic feet of acetylene per hour, a quantity scarcely higher than that consumed by a single Benzel gas burner; and yet the brilliancy was so great as to make the electric light "pale as daylight doth a lamp." As the spectrum of acetylene approaches most nearly to the solar spectrum, the delicate shades of flowers arranged on the lecture table were in no wise altered. The lecturer observed that it was sufficient to throw water on carbite, or carbide of calcium, to obtain acetylene, the lighting gas *par excellence*; but in its impure state this gas is dangerous. Its impurities attack the metals, especially copper; and the salts thus formed are transformed into explosive acetylene of copper. Acetylene itself, an endothermic substance, has a tendency to explode if its impurities permit of molecular change. Professor Pictet, however, here takes advantage of the law as to critical temperatures, by virtue of which all chemical reaction, even the most active, may be arrested by a sufficient degree of cold; and he showed that sodium—which burns spontaneously on the simple contact of water—is uninfluenced by hydrochloric acid when cooled down to about 60 deg. below zero Cent., although it is attacked when the temperature is raised to 50 deg. below zero Cent. In the same manner acetylene, a product of carbite, is uninfluenced by sulphuric acid at 50 deg. below zero Cent., while all its impurities are arrested by that acid at the same temperature; and this physico-chemical filter thoroughly refines acetylene, while rendering it liquid and inoffensive. In this state the gas is stored in nickelised steel cylinders, and a small gasometer permits of its expansion and immediate utilisation, the illuminating power being fifteen, twenty, thirty, and even forty times that of ordinary lighting gas.

MISCELLANEA.

The Turkish authorities have decided to establish a naval station in the Gulf of Alexandretta. The object is to prevent the importation of arms into Armenia, and to watch the movements of foreign naval forces upon the Syrian coast.

Mr. Jeremiah Head, M. Inst. C.E., of Middlesbrough and London, and his son, Mr. Archibald P. Head, left Liverpool last Saturday in the Cunard mail steamer Lucania for the United States. Mr. Head is consulting engineer for the company which took over the works of the Otis Steel Company in the States. Mr. Head expects to return towards the middle or end of next month.

The medals and diplomas awarded to British exhibitors at Chicago have at length been issued to H.B.M. Ambassador at Washington, and have been transmitted by him to the Foreign-office. Sir Henry Trueman Wood has been requested by the Secretary of State to undertake the duty of distributing them, and this will be done at once. *The Society of Arts Journal* says all the exhibitors may expect to receive their medals within about a month from the present date.

The deep dock in which the Volage was placed has been pumped out, and it is now possible to see the character of the injuries the vessel sustained when running over the Denrie Ferrière Rocks, in the Channel Islands, on Monday afternoon. Amidships about 40ft. of the false keel has been carried away, and although the copper plating is jagged, the main keel over does not appear to have been damaged. Astern the false keel, forward of the propeller, has been carried away for about 20ft., and it is remarkable that the rudder escaped contact with the rocks.

The Vienna papers publish obituary notices of Mr. John Hardy, the inventor of the vacuum brake, who died in Vienna on Tuesday last. He was born in 1820, at Gateshead, near Newcastle-on-Tyne, his father being a modeller. He was apprenticed to a locksmith, and worked in various factories, for some time under George Stephenson. He left England at the age of twenty-one for France, and in 1860 went to Austria as head of the repairing shop of the Southern Railways. He brought out his invention in 1878, and in 1885 retired into private life. He is believed to have been the last of Stephenson's assistants.

The Spanish Minister of Marine has applied to the Spanish Council of Ministers for special credits to the amount of £920,000 for increasing the Spanish fleet and extending the Spanish arsenals and naval establishments. The special credits include an item of £80,000 for the new first-class cruiser Reina Regente. The Spanish Minister of Marine further contemplates the construction of an ironclad to have a displacement of 11,000 tons, and to cost £880,000; two cruisers of 6800 tons each, and two torpedo boat destroyers. The Minister further proposes to equip the Pelayo with rapid firing guns, and to convert the Numancia frigate into a floating battery.

The final documents to be filed by the parties in the Delagoa Bay Railway arbitration have now been lodged at Berne. The court has appointed as experts to advise it as to the value of the concession and on the technical questions involved in the dispute between the parties, M. E. Stockalper, of Sion, who was engineer in charge of the construction of the St. Gothard Tunnel, and M. Deitler, of Lausanne, one of the directors of the St. Gothard Railway. The court has left it to these two gentlemen to suggest the name of a third expert should they deem the appointment desirable. The *Railway News* says it is probable that a local inspection of the Lourenco Marques Railway and of its Cape and Natal competitors will be made by one of the experts.

A French Commission was appointed in September, 1894, for examining under what conditions a ship canal could be made and worked between the Atlantic Ocean and the Mediterranean Sea, and what would be its utility as regards the navy, commerce, industry, and agriculture. By order of the Minister of Public Works, the *Journal Officiel* has published the report of the Commission, the conclusions of which are that a canal with eight metres depth of water would cost between two and three milliard francs, or from £80,000,000 to £120,000,000; the yearly interest on capital, with expenses of working, would amount to 93,000,000f., and that the receipts could not exceed 18,000,000f.; leaving an annual deficit of £3,000,000, while the indirect advantages would be very slight in comparison with the disadvantages of all kinds.

Her Majesty's cruiser Blake has arrived at Plymouth and reports that a fatal accident had occurred on board the ship. The Blake is one of the vessels of the Channel squadron on their way from Aberystwith to Portland. When nearing Land's End Capt. Bromley ordered a full-speed trial of the engines to be made. Soon afterwards an explosion occurred in No. 3 boiler-room, and the force of the explosion was so great that it was felt in every part of the vessel. The stokehold was immediately filled with steam, and boiling water was ejected from the boiler-tubes, severely scalding five or six of the stokers who were unable to make their escape. The *St. James's Gazette* says:—A stoker named George Evill was so severely scalded and burnt that he died soon after being got out of the stokehold, and five others were seriously injured about the face and hands. It appears that the crown of the combustion chamber of the foremost port boiler collapsed, let water out, and drove the flames into the stokehold.

On account of the difficulty experienced at Chatham, Sheerness, and Portsmouth, in securing a sufficient number of stokers for entry into the navy, the Admiralty have directed that the standard height for candidates of all ages for this rating is to be reduced from 5ft. 4in. to 5ft. 3in. until further notice. Authority has been given to enter stokers at the rate of 690 each quarter, divided among the recruiting districts as follows:—Portsmouth, 349; Devonport, 172; Chatham and Sheerness, 169. Allowing for a wastage of 1000 men during the current year, the number of stokers in the service will be increased by 1762 by April next if the proposed entries can be effected. In this department of recruiting, the *Naval and Military Record* says, Devonport has been so successful that the recruiting officers of the district are frequently requested to stop further entries several weeks before the end of each quarter, and on this account alone it is to be regretted that the order to reduce the standard height has been made general instead of applicable only to districts where a difficulty is experienced in getting recruits.

At the ninth summer meeting of the Institute of British Carriage Manufacturers, held on the 24th inst. at the Mansion House, the President—Mr. George J. Jacobs, F.R.A.S.—read his address, which dealt at some length with the history of the improvements in carriage building. He mentioned that as far ago as 1846 the india-rubber pneumatic tire, on the principle of those so much in favour to-day, was applied to carriages by W. Thomson, C.E., of Adelphi-street, Strand, but the invention was not satisfactory, and was relegated to the long sleep from which it has but lately emerged. They stood that day, he continued, on the outer confines of a great departure. They were told that the horse would shortly be removed from its pedestal of autocratic rule and monopoly of possession of the roads for vehicular traffic. The autocar might be taken as the latest application of science to their manufacture. The leaders of their industry regarded the advent of that movement with much interest and expectation, but without panic or alarm. If the carriages of the future were increasingly light, easy, and elegant, they had nothing to fear from, but rather should welcome, the new comer. The result of any satisfactory progress in the adoption of self-impelled vehicles would be the liberation of the horse from its heavier and trade burdens, which would be to the advantage of the manufacturer of horse-drawn vehicles of the lighter kind.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

C. E. H. (Wolverhampton.)—*Write to the secretaries of the Institution of Civil Engineers, Gt. George-street, Westminster, and of the Institution of Mechanical Engineers, Victoria-street, Westminster. You must have had a regular engineering training.*

"THE PIERRE BŒUF BOILER."

(*To the Editor of The Engineer.*)

Sir,—I should feel much obliged if you would kindly insert an inquiry in your correspondence column for the makers of a steam boiler known as the "Pierre Bœuf." It is described to us as a French make, and as being somewhat of the Lancashire type, with a multitubular arrangement on the top. Enquirer.

Pershore, June 22nd.

[Does our correspondent refer to a boiler or boiler parts made by Piedbœuf's, the tube and boiler manufacturers, of Dusseldorf.—Ed. E.]

SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. £0 14s. 6d.
Yearly (including two double numbers) .. .. £1 9s. 0d.

If credit occur, an extra charge of two shillings and sixpence per annum will be made. The Engineer *is registered for transmission abroad.*

A complete set of The Engineer *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
Half-yearly .. .. £0 18s. 0d.
Yearly .. .. £1 16s. 0d.
Thick Paper Copies—
Half-yearly .. .. £1 0s. 3d.
Yearly .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of The Engineer.

MEETINGS NEXT WEEK.

Dundee Institute of Architecture, Science, and Art.—The Annual General Meeting will be held in Y.M.C.A. Rooms, on Tuesday 30th instant, at two o'clock p.m., and the Council trusts there will be a large attendance of members. Business: (1) Annual Report and Balance Sheet. (2) Election of Office-bearers and Councilfor ensuing session. (3) Election of Committees.

THE ENGINEER.

JUNE 26, 1896.

THE DRUMMOND CASTLE DISASTER.

The appalling disaster which has befallen one of our model steamship companies by the wrecking of the Drummond Castle, and the loss of nearly two hundred and fifty passengers and crew who were entrusted to her captain's care, has once more raised the question whether nothing can be done to make navigation absolutely safe, or, if that be impossible, whether a ship cannot be built so as to afford a reasonable chance of escape to those on board when her last hours have come. Naval architects will reluctantly have to admit that no conceivable system of construction could make a steamer unsinkable; nor can even the best of navigators feel sure that under his command a ship would evade every danger to which she might be exposed. Much has been done to provide him with instruments and appliances of the greatest accuracy, but even these have not proved themselves to be uniformly trustworthy. Thus, in spite of the very painstaking marine surveys which our Admiralty are always carrying out, many a ship has been beforehand with them in finding an unmarked rock; and the compass, the log, the sextant, and the chronometer—good as they may be—are never depended upon absolutely by experienced men. Not only are they worked in duplicate, but the one set of instruments is used as a check on the others; and if the ship's position by the compass and log does not agree with the astronomical observations, an amount of caution is exercised by practiced navigators which to the younger members of that profession may seem ridiculous, but which are fully warranted by the circumstances.

While writing this article the cause of the loss of the Drummond Castle has not been ascertained, and we therefore feel at liberty to echo the general inquiry as to why she went out of her course, why the Ushant lights were not seen. As yet it is not known whether the voyage was made in good or bad weather, or, in other words, whether the steamer had been navigated by the log or by the stars; if by the former alone, her position would be one of considerable uncertainty, for not only might her course have been affected by temporary, and therefore unknown, ocean currents, but the log might have become deranged, possibly by striking a piece of wreckage, which would bend its blades, or by being fouled. There is also a possibility of the compass being out of order. It is well known that vessels which travel between the northern and southern hemisphere require to have their compasses specially adjusted so as not to be influenced by the change of dip due to variations of latitude, or else the ordinary compensations or corrections have to be modified as the vessel approaches either pole. As the Drummond Castle was built with her head pointing in a south-easterly direction, while her course from the Cape would be about north, a violent blow from an exceptionally heavy wave might have suddenly reversed her magnetism. Such cases are rare, but one was mentioned not so very long ago in which a steamer was severely struck by a wave, and immediately afterwards it was found that her compasses had acquired a deviation of 20 deg., and had the weather not been clear, she would most certainly have been wrecked on the Irish coast. But even without going so far in search of a possible reason, it is only necessary to recall to mind that in bad weather even the best equipped Atlantic liners sometimes find themselves far out of their correct course. This has occasionally resulted in strandings, but there are many more cases in which fortunately the errors were detected in time. Instances could be mentioned of mail steamers having been steered straight for Scotland or for France instead of for the south of Ireland, one of them nearly coming to grief where the Union steamer European was wrecked in 1877, and where the ill-fated Drummond Castle now lies. Of course, in such cases the sky has invariably been overcast all the way out; but it shows how untrustworthy the compass and log may prove themselves to be. The danger is in a way only increased by modern improvements professing to reduce the possible errors to infinitesimal amounts, because they inspire a confidence in their accuracy which is not warranted. Thus, for instance, in the above-mentioned case the compass was of the most approved pattern, and could be depended upon to indicate the correct course to within one-tenth degree, and yet one heavy blow from a tidal wave introduced an error of 20 deg., of which one would have had no suspicion if the night had not been clear.

Somewhat similar remarks apply to lighthouses; they too have been made so numerous, powerful, and easily distinguishable, that it seems almost impossible to approach a coast without seeing them, and yet as the wreck charts show, more ships are lost through strandings than through any other cause. Of course, when it is foggy one does not expect to see a light, and the most elaborate precautions are then taken to guard against accidents, but these are almost invariably relaxed a little when there is only a slight haze on. Yet mariners ought to know that the danger is then equally great, for a bank of fog may be surrounding the light and not reach to the ship. Of all the atmospheric conditions snow is admittedly the most dangerous; not only is it far more effective than fog in hiding a light, but it also deadens the sound of fog horns. Rain, particularly a fine drizzle, is almost as bad; for although it does allow some light to pass, it interferes with vision by being blown into the eyes and the face of the look-out man, who naturally seeks shelter, either by not looking straight into the wind's eye or by peeping out from behind any object which will intercept the rain a little. There is yet another danger, and one which may perhaps account for the fact that the Ushant light was not seen. The glare from the reflection of the two electric side lights of the vessel herself against the fine rain may have effectively hidden the lighthouse from view. The Drummond Castle, like most of the boats of her line, carries her side lights forward in so-called lighthouses; the more powerful these lights are, the stronger will be the halo of light in front of the ship when there is a fine rain, and the shore light would then be less easily seen than if everything were dark. It is for this reason that some ships have discarded electric side lights for those of oil, or have shifted them from forward to near the bridge-house. According to one of the first reports, but this has not been confirmed, she was distinctly seen from the lighthouse; and if this was really so, the fine rain could not have been sufficiently dense to hide the shore light; and if, as there is every reason to believe, it was shining brightly all the time, it could only have been hidden from view by some screen, and the most probable one would be the glare produced by the reflection from the side lights on the drops of fine rain. Perhaps before these lines go to press the mystery may have been solved by some other explanation; but the dangers which have been pointed out are none the less real, and have led and will lead to accidents.

As regards the sudden sinking of the ship, there is very little to be said. The Drummond Castle was 365ft. long, 43½ft. beam, and 32·7ft. moulded depth, with an underdeck tonnage of 3537. She had eight water-tight bulkheads, or nine compartments, including the forward peak, and she had a short double bottom aft of 40ft. length. A deep water tank of 20ft. length appears recently to have been converted into a hold space, so that out of a total length of 365ft. only 40ft., or a little more than 10 per cent., were protected against the dangers which attend a stranding. As regards the ship's subdivision, or floating capabilities when injured, it may be assumed that the load draught displacement would be about 7000 to 8000 tons, and that her spare buoyance to the upper deck would add another 2000 to 3000 tons. On an average, one of her nine compartments, if filled, would hold about 1000 tons, and the engine and boiler space would hold quite double that amount; so that it is quite conceivable that a hole in the ship's bottom, extending to either side of either engine-room bulkhead, would admit enough water to sink her, and as she sank so very quickly, it is only reasonable to suppose that the hole was a very large one, and may have extended over a length of three or more compartments. In fact, she probably ripped a great part of her bottom out. It should also be remembered that the vessel may have been travelling at a speed of 14 knots; the rock of the coast is granite, and one of the survivors heard a long grating noise. The amount of energy available for her own destruction, due to a mass of 8000 tons travelling at the rate of 14 knots, is 60,000 foot-tons. If we assume that the length of the hole in the ship's bottom was 150ft., a distance which she would travel in about seven seconds, then the available tearing force would have been 400 tons, a force which is amply sufficient to overcome any resistance which the skin plating and the ship's frames might have offered. No surprise need, therefore, be felt at the rapidity of the disaster; in fact, even if the vessel had only been going seven knots, the available destructive energy would still have been 15,000 foot-tons. There is no need in this case to inquire whether there were enough bulkheads, for, with a long hole in her bottom, no amount of vertical subdivision could have saved her; but there can be no doubt that if she had had a double bottom over her whole length, or even if it had extended over her forward length, there is every probability that she would have remained afloat. Most modern steamers are now built on this plan; for since it has been shown how to utilise these tanks for stiffening the hull, considerable concessions have been made as regards the scantlings and reductions of weight. The fact that the insurance premiums on double-bottomed ships and their cargoes are lower than on others has already led to their almost universal adoption even by the largest mail boat companies; and it is a significant fact that, with a view of reaping the full benefit of lower premiums on cargoes, and therefore higher freights, almost all these companies are now having their steamers built to class in one or the other societies in order that authentic information as to bulkheads, double bottoms, engine power, and many other items which affect the safety of a ship, may obtain a wide circulation. The travelling public are largely influenced by questions of comfort, but in view of recent terrible shipping disasters which could, perhaps, have been averted by proper constructions, it is more than likely that before embarking they will in future inquire whether their ship is sufficiently subdivided to keep afloat after a collision, and whether she has got a double bottom which would protect her against the dangers which attend grounding.

THE POSITION OF THE MECHANICAL DRAUGHTSMAN.

The mechanical draughtsman has been wittily but ungenerously styled a "necessary evil," and that he is so considered by a large number of employers is probably a fact. The reason is obvious. For the work done in the drawing-office there is no direct tangible return. The handiwork of the smith, the fitter, the turner, form part of a hard material mechanism which can be sold for a price. The work of the draughtsman—the actual sheets of drawings and tracings—are not for sale; the time and thought, absorbed, as it were, into solid brass and iron, are overlooked—forgotten. The thought is, indeed, embodied in the machine, but the machine is sold by weight and time of labour, not by the measure of thought. This is very illogical, but by no means incomprehensible. We have heard people grumble about the money spent on the police force. What is the policeman to them? A useless item; an absorber of taxes; one who wears out in useless peregrinations the boots of the ratepayer. Again, we say the position taken up by these good people is easy to understand. They see no direct return for their money, and, therefore, they question if the money is well spent. It must, indeed, seem to them like throwing bread upon the waters, and possibly there are moments when they long to be assaulted or burgled, that in the form of constabulary duty their bread may return to them after many days. It is not impossible that the employer has a somewhat similar way of considering his draughtsman. The draughtsman is not a man who asserts his position. He is a man who, as a rule, works and grumbles all the week, and smokes to forget his worry all Sunday. We should not be writing this inflammatory article if we anticipated that it would have the least effect on the draughtsman; but we feel that it is quite safe, and we address ourselves rather to the employers than the employed. Of course there are draughtsmen and draughtsmen. There are those who are barely worth what they receive, and we scarcely think it possible to be worth less; and there are those who should receive fivefold. We know there is a fancy amongst employers that they do all the work, or that their chief designer does it. It is easy to be so mistaken. A scheme resolved out of a hint given to a draughtsman looks exactly like the thing one had conceived in one's brain, but had allowed another to put on paper. The suggester imagines himself the designer and inventor, even though the draughtsman has spent weeks of thought and quires of paper in knocking a crude idea into shape. Let the same suggester take himself the board and the tee square, and try to lay down on paper the thing he has conceived, and he will find that at every point his imagination has deceived him. Here the thickness of metal prevents one arrangement, and there the thinness of it prevents another; here the impossibility of machinery is an insurmountable obstacle, and there the cost of forging or moulding needs deep consideration, and so on and so on. From the moment the first centre line is drawn on the paper to the time the drawing is ready for the tracer, it is unceasing thought and responsibility. Responsibility is, after all, the thing that has to be paid for; and the draughtsman is obliged to take more than his share. Whatever goes wrong, be it in shops or offices, the blame will if possible be thrown upon the drawing-office. The chief draughtsman bears the brunt of it, perhaps being held responsible for all work turned out by his staff; but he quickly dislodges the burden and drops it on to the shoulders of his subordinates. Theoretically he may be responsible for all drawings issued, actually that is impossible. It is the draughtsmen at the boards who are and must be of necessity the finally responsible persons, and in consideration of what that implies the remuneration is painfully inadequate.

It is a favourite argument with certain philosophers that a worker always receives what he is worth; this implies that the man who will do the work for the lowest possible wage is the standard of worth for all others. If an employer can get a draughtsman to do the work he wants done for 35s. a week we cannot expect him to pay more. At present the only known cure for inadequate wages is amalgamation. Now we are very strongly opposed to the combative amalgamation of the artisan class, and by no means do we wish to see draughtsmen binding themselves with any such treacherous cord, but there is an amalgamation of etiquette well understood in many professions which might be adopted, not without advantage, by draughtsmen. It may be well said that the standard among draughtsmen is not sufficiently high; that whereas in the professions alluded to a refined education has given men the necessary amount of pride and good feeling to make them ashamed of losing caste by lowering their own worth and that of their fellows, the draughtsman has not infrequently raised himself from the bench or marking-off table. This is to a large extent true, but at the same time if once the remuneration for good work was made fairer we should find better educated and more capable men ready to accept the draughtsman's position. As it is, there is a very large number of young men with college and shop experience compelled to work at the board for the same price as the man almost without education. We know very well that the college training is actually in many cases a drawback, but still advertisements may not infrequently be seen for draughtsmen with "scientific attainments preferred," and these men will perhaps be expected to work for a price per hour equal to or lower than the wage of a good mechanic. It must be understood that we refer here to actual draughtsmen, not chiefs or designers; these, as a rule, are more fairly paid, though we could mention cases of chiefs, with twelve to sixteen men under them, being paid about £150 per annum.

The standard of work done should, of course, be the measure of the pay given. If a man is only sufficiently competent to put together a general arrangement from the detail plans, or to make unimportant alterations in existing drawings, his pay should be made adequate to this class of work. If he is found capable of working up ideas unassisted, of doing all the necessary calculations, and of scheming the hundred-and-one little arrangements which a new design always necessitates, his pay should naturally be greater, and so indeed it is, but quite disproportionately. Thus the first will perhaps receive thirty-five shillings a week, and the second forty. It must be perfectly evident that the pay is totally disproportionate, both to the intelligence involved and the responsibility undertaken. Admit that the first man is worth thirty-five, and the second must be worth at the least twice that sum.

It might not be impossible to make some compensation to the draughtsman for the indifferent remuneration by certain polite concessions. His social position might be more regarded, by which we mean that he should expect and receive more delicate treatment than is accorded to mechanics, instead of less. His personal comforts, the sanitary arrangements of the drawing-office might be much improved. He might be allowed a little more liberty in the matter of time-keeping, and not find himself "docked" 3½d. for a quarter of an hour's leave. His pay should be a standing pay, and not dependent on his punctual attendance, and he should be allowed certain holidays in the year without the curtailment of his income. All these things are done in many drawing-offices, notably so, we understand, by the large railway companies, who work shorter hours and are less exacting than most offices. But, after all, the majority of employers, even very large companies, do not deal at all generously with their draughtsmen.

As we have said before, we only know of one accepted method of correcting these faults, and that is a way which, although good in itself, has become notoriously bad from misapplication. There are, however, throughout the country many draughtsmen's institutions, and if a collective appeal was made by these to the employers, we think it highly probable that the draughtsman could considerably better his condition. Let there be, however, no confusion between draughtsmen and tracers. Tracers probably earn very much what they are worth, the work is purely mechanical, and only in exceptional cases needs the application of mental powers. The draughtsman, on the contrary, must always bear a heavy burden of responsibility, must be continually exercising his brain, and must be dexterous with eye and finger. The tracer's craft may be learnt by a man of indifferent intelligence in a month or two; only a regular course of engineering training makes a thoroughly competent draughtsman, as only long experience produces first-class designers.

It is with certain misgivings that we write this article. Anxious as we are that the position and condition of the mechanical draughtsman should be more commensurate with the abilities demanded in him, we do not wish by the slightest hint to favour any rupture between the drawing-office and the employer. It must be evident to the latter, however, that there will be in time a draughtsmen's society, even as a medical doctors' society is mooted now; and as such things are generally the cause of some disturbance, would it not—we put the question to the employers—be prudent to meet matters half way and make certain concessions in the draughtsmen's favour before they are demanded with a show of arms?

THE NAVAL ARCHITECTS IN GERMANY.

Nothing could exceed the cordiality and enthusiasm with which the Institution of Naval Architects has been received in Germany. As Sir W. H. White aptly put the matter, all that were great or important in the social, scientific, or mercantile world in Hamburg welcomed the visitors on their arrival in that city; whilst in Berlin the directors of all the principal companies, the Secretaries of State, and many of their most influential officials, and, finally, the powerful and intelligent ruler of the vast empire of Germany himself, all vied with one another in holding out the right hand of friendship to the shipbuilders from across the North Sea. The time was opportune. As the Earl of Hopetoun hinted in his opening address, newspaper men had been stirring up—or trying to stir up—ill-will between the two countries. They were at the bottom of all the mischief that was done. The moment was, therefore, a happy one for bringing together men of two great nations, allied by ties of brotherhood, by ties of scientific knowledge, and by ties of commercial interest and trade industry. The occasion could not fail to indicate to them, when brought thus into juxtaposition, their common interests in trade and manufacture, more especially in the development of that great science of which the Naval Architects were the exponents—the art of shipbuilding. What that art can aspire to be was most happily put by Admiral Hollman in his address at Berlin. A ship was a thing of life as well as beauty. But the time was opportune in another sense. It was a graceful act on the part of Germany to call the Institution across the water to see what the country had done by following in the steps of her maritime sister. She was ready to admit that her new shipyards, her latest vessels, her most powerful battleships, her most recent specimens of machinery, were developed from British models. It was, therefore, due to that great country, which had given to Germany all those ideas, that she should contemplate the fruits of her instruction in the past, as an incentive to fresh exertions upon the part of the parent teacher in the future; and we confidently believe that, apart from the question of all the oil that has been poured upon the troubled waters of feeling in Germany and England, a great and lasting benefit will result to our own country. It has been shown to us that we cannot stand still. Whilst we are employing, in our manufactories and shipbuilding yards, plant that "might have been young and effective some forty years ago," Germany is starting afresh. It is the old story of the hand loom over again. There are men in our country who love nothing until it is old or unserviceable. Witness the scientists at Woolwich, who clung for eight years to the muzzle-loading gun. But trade and industry must not be trifled with in this way, however war may be carried on. The industries and trade of a nation will perish unless conducted upon the most recent and improved principles. Hence the visit to Germany of the Institution of Naval Architects, and the exhibition which it had of the development, the energy, and resources of the people of that country, should have the effect of stirring us up to see that our muscles are braced and our house in order. May this be the result of the summer meeting of the Naval Architects of 1896.

TRADE REVIVAL.

A trade revival of an undoubted character is appearing in some of the iron and steel and heavy engineering centres of the country. From the North of England, the West of Scotland, Barrow-in-Furness, Lancashire, and the Midlands reports come of an increased demand, stronger prices, and added activity at the works. All this is very satisfactory, and happily finds a reflex in some of the reports of the public companies connected with iron and steel manufacture which are just now being issued. John Brown and Co., of Sheffield, for example, announce this week that the improvement in the trade of the country has had a most beneficial effect on the general business of the company, and the various departments producing railway and shipbuilding material have done better than for some years past. The armour-plate department has been well employed, and the output of the collieries has been considerable. Similarly one of the leading Welsh coal and iron concerns, the Tredegar Coal and Iron Company, are able to advise this week that the output of coal during the year ended March last was the largest on record, namely, 910,288 tons. One of the rail mills has been started on the manufacture of light sections of rails, and the wagon repairing and other shops have been extended and fitted with additional machinery. The report of Nettlefolds Limited, Birmingham, one of the largest and most prosperous engineering and iron and steel concerns in Mid-England, contains a recommendation of a dividend of 10s. per share and a bonus of an equal amount on all the ordinary paid-up capital, in addition to the usual preference and other divisions. We give these instances as passing evidences of the improvement that seems to be setting in, but they might be multiplied many fold. The shipbuilding and steel plate and steel rail trades of the country are all looking better, and at most of the industrial concerns, particularly on the Clyde and the North-East and West Coast, concerned in these industries, the machinery is running almost constantly. Steel rails have advanced £1 per ton on the prices of eighteen months ago, and at some of the steel works in West Scotland, engaged mainly in the plate trade, the output is as high as 3000 tons weekly. Comment is made that the difference in prices at the moment of steel plates and iron bars should be only 5s. per ton, whereas under normal conditions 20s. per ton is the usual difference. The present position is, however, due to the fact that the production of plates has increased enormously, while that of iron bars and angles has not, and, if difficulty is prevented in the coal trade, everything points to a continuance of the trade revival for some months certain.

YORKSHIRE MINING IN 1895.

Some interesting particulars are published in the annual report of Mr. Frank N. Wardell, her Majesty's Inspector of Mines for Yorkshire and Lincolnshire. One is the immunity this great coalfield has happily enjoyed from disaster of any magnitude. With the exception of an explosion of gas near Wakefield, which caused the death of two persons, no single accident resulted in the loss of more than one life. Another point is the gradual decrease in the number of persons following the occupation of mining. In 1894 there were 91,154 people employed in the production of minerals in these two counties; in 1895 this number had been reduced to 88,879, showing a falling-off last year of 2275 persons—this, be it remembered, in the face of many new collieries, being opened out. The conclusion is that in the mine, as in other places of labour, the machine is displacing the man. This is one of the results of triumphant Unionism. "No reduction" sounds very well at miners' mass meetings, and the resolution to adhere to "a living wage"—which nobody has yet attempted to define—is enthusiastically endorsed. But it all comes to the same thing in the end. The amount paid in wages is maintained, but the work upon which wages is paid is diminished. At the week end the worker takes less home. The "living wage" is even less a living wage than if the coal-owners had been able to take more contracts by getting the cost of production lowered to that in other districts. At the same time the output for 1895 was considerably less than for 1894—sea-borne coal being placed so much cheaper on the metropolitan market. The weight of coal raised in the former year has been 22,807,507 tons, or 694,667 tons less than in the previous twelve months, including fire-clay, ironstone, and similar minerals, the total output in 1895 was 23,319,486 tons, which is 650,279 tons less than in 1894. Considering that many collieries during the year were not working more than three or four days a week, Mr. Wardell anticipated that the decrease would have been still greater. The number of deaths from falls of roof and sides again makes the heaviest item in the casualties, the figures being 56 and 39 respectively. In the year 1895 there was a proportion of one death to every 977 persons employed. Every 256,258 tons of mineral produced in the district costs a life. Of the 88,879 miners employed, 88,680 are in Yorkshire and only 199 in Lincolnshire.

THE SOUTH YORKSHIRE COKE TRADE.

In the present unprofitable and unsettled state of the coal trade, it is some satisfaction to learn that the coke trade so largely carried on in South Yorkshire is in such a state as to provide an outlet for the small coal, slack, and smudge raised, which sells freely at improved rates. This may be said to be about the only active branch of the coal trade. The activity of the coke trade and the short time worked at the collieries is causing small fuel to be somewhat scarce, and, of course, prices have increased to such an extent that secondary qualities of unscreened house coal can be procured at about the same prices as are demanded for best screened slack, which has reached 3s. 6d. to 3s. 9d. per ton, whilst smudge, which at the beginning of the year could be procured at 9d. to 1s. per ton, makes 1s. 6d. and 1s. 9d. per ton at the pits. The value of proper screening machinery is thus proving itself by a direct increase in the prices of the output everywhere. The output of coke throughout South Yorkshire is now large. All available ovens are at work, and within the past month a large number, which have been disused for years, have been relighted at Silkstone Common. New ovens are in course of construction at Cadeby Colliery, near Mexbro, and at the Barrow Colliery, Worsbro, near Barnsley. Makers, however, complain that supplies are becoming more plentiful, and the increased prices of fuel have a tendency considerably to curtail the profits derived from the advanced prices. A large portion of the coke made is sent to North Lincolnshire, Derbyshire, and Northamptonshire, at all of which places district makers have to compete with North of England producers.

LITERATURE.

La Règlementation de la Production du Charbon. By Emile Lewy. Paris: Librarie Française et Anglaise de J. H. Truchy.

The author of the above work has undoubtedly devoted a great deal of thought and time to his subject, and he propounds at considerable length his views with regard to the production of coal on lines which would, he maintains, be satisfactory alike to master and man. Mr.

Lewy has gained his experience of the miner and mining as managing director of a Belgian colliery, and the outcome of his reflections on the subject has resolved itself into a fixed conviction that he can solve the labour question, at all events as far as coal mining is concerned, if only the people interested would follow his advice. This is precisely where his difficulty has come in, nor is there the slightest probability of its being overcome. If perseverance, energy, and conviction of purpose are to be taken as indicating feasibility, then Mr. Lewy should succeed, for he brought out his first project some years ago, since which time he has submitted it in various forms and languages, and with unflagging persistence, to most of the trade union leaders connected with the European coal industry.

The first portion of his book tells us how these gentlemen received his propositions. Most of them sympathised with the scheme, and a few offered criticisms on it. Enough interest was taken in the subject to enable him to bring it before the various international mining conferences that have taken place of recent years, and an unimportant, and now defunct, labour paper in this country gave all the support and advertisement that it could to the project, and anything which the author chose to write on the subject. The international conferences, however, ruthlessly shelved the "projet Lewy," until at last the matter was discussed at the 1895 Paris conference. The result of the discussion left matters practically *in statu quo*, the delegates again offered their sympathy, but any attempt to get away from generalities and discuss the details caused so great a dissension of opinion that no progress could possibly be made.

Leaving all the sentiment out of the project, all the talk about the downtrodden miner, the living wage, the starvation prices at which coal is sometimes sold, and so on, Mr. Lewy's scheme, in a few words, may be described as a proposal to form a compact ring of the coal trade in all European centres, for the supposed benefit of man and master, and certainly at the expense of the coal-consuming public. The middleman is, as one might expect in such a book, strongly condemned, but, in the same breath, and with great inconsistency, the author holds up to opprobrium the large coal consumers, such as gas and railway companies, who purchase in sufficient quantities to enable them to do without the services of the middleman.

We are told, and we can quite understand it, that the masters were extremely unsympathetic with regard to the scheme. The most favourable answer which Mr. Lewy could obtain from them was, to quote his own words:—"First of all, you must come to some understanding with the men, and then we will see what can be done. Until then we can do nothing." Mr. Lewy's main argument is as follows: The miner demands a living wage, and it is his right to have it. To fix a minimum rate of wages the miner must be accorded 25 per cent. of the profits. The mineowners desire a reasonable return for their capital, and this is just too. This state of things is the cause of all the labour troubles in the trade, says the author, and it is due to a want of equilibrium between production and consumption. This causes undue competition, and sends first the miner and then the master to the wall. A remedy must be supplied which will relieve master and man alike. This remedy is to be the regulation of production to suit the market, and it is to be brought about by an international agreement between the men's representatives. The owners cannot agree, as their interests are too divergent, and so the men must carry out the plan. The interests of the men are so identical "that they cannot fail to be unanimous." The agreement the men are to come to is to the effect that they shall only work a few days a week according to the district, and that they are to be paid for one day more than they work. The eight hours day is to be universal, though Mr. Lewy ignores the fact that many British coal miners do not work anything like eight hours a day. No stocks are to be kept beyond the bare necessities of the trade, whatever that may mean, and the wages are to fix the price of coal. The master is to say to the consumer, "That is the price. You can take it or leave it." No doubt such a policy would often result in the customer leaving it; for, as Mr. Lewy justly remarks, the price of coal very often determines the profit or loss of gas and other large companies. So the natural result would only be that if such companies had continually to buy their coal at prices which would guarantee their always working at a loss, they would soon stop work. Thus the immediate result of adopting Mr. Lewy's scheme for a millennium in the coal trade would be the ruination of the best customers of the coalowners.

Mr. Lewy no doubt means extremely well, and is very convinced of what he says, but unfortunately his book is not in the least likely to prove convincing to any but the most unsophisticated student of labour matters. There is small matter for wonder that even the extremists in trade unionist and socialistic circles cannot as a rule bring themselves to believe in it. The author's arguments are at once fallacious and naïve, but the book in some ways is not without interest as a record of the different methods adopted for politely burking the question by the several well-known men in this and other countries to whom the scheme has been submitted. One naturally sympathises with any proposal to improve the lot of the coal miner, which is undoubtedly a hard one. But Mr. Lewy tells us that the wages earned by the British miner are at least three times as great as those of his Belgian *confrères*, and we cannot help thinking that Mr. Lewy has begun at the wrong end of the question. He might with less difficulty do much good in endeavouring to level up the wages and reducing the working hours of the continental miner to some figure more nearly approaching the English standard. This will be an absolute necessity before any scheme, good or bad, for an *entente cordiale* of an international character between coal miners can stand any chance of being seriously considered.

Computation Rules and Logarithms, with Tables of other Useful Functions. By S. W. HOLMAN. Large 8vo. pp. xlv.—73. New York and London: Macmillan and Co. 1896.

"IT would probably be within safe limits to assert that one half of the time expended in computations is wasted through the use of an excessive number of places of figures, and through failure to employ logarithms. This waste may be almost wholly avoided by following a few simple computation rules and practising slightly with logarithm tables." In order to facilitate the saving of time and labour indicated in the foregoing paragraph, the author has brought together a series of simple rules to enable the user to answer for himself the question, How many places of figures ought I to use in this computation? There are also explanations of the use of notation by the powers of ten, and instructions in many respects novel as to the use of the tables; these preliminary matters forming an introduction of forty-five closely printed pages to the tables which follow. The collection is designed to contain all the mathematical tables ordinarily required, *and nothing more*—the italics are our own—in practical work in all branches of the engineering profession, and by students of physics, chemistry, and engineering, for work of any degree of accuracy not exceeding 0·05 per cent., and it should therefore provide for many persons all the logarithmic and trigonometric tables needed for the entire range of their practice. The tables include ordinary and trigonometrical logarithms, both to four and five places, besides square roots reciprocals, and natural sines and tangents to four places. A table of slide wire ratios as used in electrical measurement, and a series of the more useful numerical contents, all of which are well selected, so that the promise to include nothing more than essentials has been fully carried out. There are several minor novelties in the arrangements calculated to make the use of the tables easier, and the introduction contains much information of which even experienced computers may be glad to be reminded at times. The work is excellently got up both as regards type and paper, although the latter is perhaps rather too thick to be quite agreeable in use, although this may not be a failing in a volume intended for hard and constant service.

Crystallography for Beginners; with an Appendix on the use of the Blowpipe. By C. J. WOODWARD, B.Sc. 8vo, pp. 164, with 4 plates. London: Simpkin, Marshall, and Co. 1896.

THIS volume contains a series of lessons on the simpler parts of descriptive crystallography, such as the different systems of notation, the notation of faces and forms, and the use of the spherical projection in determining the symbols of faces from their observed angles, &c., each lesson being accompanied by a series of exercises, and illustrated by models to be built up from their developed surfaces given in the accompanying plates, as well as by a small collection of characteristic, natural, and artificial crystals, which can be obtained from Messrs. White and Pike, of Birmingham, for 3s. 6d., and is intended, in addition to its principal purpose, to facilitate the performance of simple physical experiments, such as Senarmont's demonstration of the ellipsoid of heat conductivity in gypsum. The author has, we believe, been a successful teacher of the subject to elementary students, and therefore his method deserves attention; but a consideration of the book leads us to the conclusion that such success can only be obtained by the use of a larger amount of material than is here presented to us. So far as it goes the material is good, but the quantity is even scanty for elementary use, and the deficiency is made more apparent by two thoroughly incongruous additions in the shape of an appendix on the use of the blowpipe, and an abstract of Dr. Albin Weisbach's tables for the determination of minerals by other characters than form, which, considering the main purpose of the book, are most decidedly out of place, and take up space that might more usefully have been devoted to some of the simpler problems of determinative crystallography, such as the establishment of the fundamental axial ratios of a species from observed angles, the principles of twin structure, the use of linear projections, &c. In places the author's language is not remarkable for accuracy, as, for instance, where he talks of planes of symmetry contained in plane figures, cubic crystals of apophyllite, regular octahedra with 12, 14, or 18 edges indifferently, and gives as a method for drawing crystals in isometric perspective one that is palpably anisometric. Such slips as these are unfortunate in a work of this kind, as they are likely to be a trouble to students, especially those without much preliminary geometrical training, for whose use it has probably been designed. The sheets of models in the illustrations are rather roughly executed, and are scarcely likely to make up satisfactorily. Probably their best use will be as guides for re-drawing them, which should be done on the best Whatman paper, using a finely-pointed hard pencil for setting them out.

SHORT NOTICES.

The Great Eastern Railway Company's Tourist Guide to the Continent. Edited by Percy Lindley. Illustrated, and with maps. London: 30, Fleet-street. 1896. Price 6d.—This is the seventeenth annual issue of a useful little book. Amongst its new features are a chapter on cycling routes in Holland, Belgium, and Germany, and some continental maps, including one, large and clear, showing the continental railway systems.

The "Private Bills" Reports: A Record of Proceedings in Parliamentary Committees during the Session 1895, *including cases of locus standi in the House of Lords.* With maps and index. Compiled by Herbert Newbon, of the Inner Temple, barrister-at-law. London: Eyre and Spottiswoode. 1896. These records of the proceedings of Parliamentary Committees will be found very useful by the many engineers and solicitors, and many others who are frequently occupied upon or in connection with committee and private Bill work, and to others to whom precedents are of importance. On some matters, such as the London Water Supply and Roads Locomotives, for instance, the facts and figures quoted and the plans referred to will be of value to many. The Bills dealt with in this volume, which is well printed with large type, marginal notes, and dates, relates to railways and docks in Wales, except the Mersey Docks and Harbour Board Bill, and maps are given of the districts concerned in each case. The work of the compiler appears to be well done, and no doubt will be appreciated.

BOOKS RECEIVED.

Rivers and Canals. The Flow, Control, and Improvement of Rivers, and the Design, Construction, and Development of Canals both for Navigation and Irrigation. With Statistics of the Traffic on Inland Waterways. By Leveson Francis Vernon-Harcourt, M.A., in two volumes. Volume 1, rivers; volume 2, canals. Second edition, rewritten, enlarged. Oxford: At the Clarendon Press. 1896. Price 31s. 6d. the two volumes.

Proceedings of the Twenty-ninth Annual Convention of the American Institute of Architects. Held in the St. Nicholas Hotel, St. Louis, October 15th, 16th, and 17th, 1895. Published by the Board of Directors, A.I.A., under Direction Committee on Publication and Library. Alfred Stone, editor. Providence: E. A. Johnson and Co., Printers. 1895.

THE ROYAL INSTITUTION.

NIAGARA POWER WORKS.

ON Friday, the 19th inst., Mr. L. Commerford Marten, editor of the *Electrical Engineer* of New York, gave an address upon the Niagara power scheme in the theatre of the Royal Institution, Albemarle-street. Lord Kelvin presided, and there was a large and distinguished audience, including some of the principal engineers of the day.

The lecturer showed a fine series of lantern slides, and was anxious to impress upon his audience the fact that the Power Company had not injured the scenery of the place; when near the Falls it was impossible to see, even with an opera-glass, the works which have been carried out by the company to bring the water to their power-houses. Views of Niagara in its summer and winter aspects were then thrown on to the screen, and the lecturer stated that the total height of fall, including the Rapids, was 320ft., and there was 164ft. clear fall. In 1725 the first saw-mill was erected there and driven by water power. Sir William Siemens had estimated the available power of the Falls at 17,000,000-horse power, and Professor Unwin had given the much lower estimate of 7,000,000-horse-power.

Views were then shown of the canal, the power-house, turbines, dynamos, and tail race tunnel, and it was explained that the present scheme was for 10,000-horse power. Some amusing examples were given of schemes which were sent in for competition. One of these showed plant placed in chambers excavated behind the Falls, with vertical tubes so arranged that the water poured direct into them, and was intended to flow down to the turbines. The lecturer said that the author of the scheme was asked what he would do if icebergs dropped into the pipes. It appears that the power is being well taken up, and that three of the large units are now at work. Extensions are to be made at once; in fact, the contracts were let before the lecturer left New York, and one of the most interesting points mentioned was that several firms have tendered for dynamos to produce 10,000 volts at once, so that it will not be necessary to transform up for the line current. The author referred to the choice of 25 cycles per second for the alternating current, and pointed out that this frequency had been selected because the current was to be used specially for the distribution of power. It is, of course, rather a low frequency for incandescent lighting. The weight of each generator is 170,000 lb., of which 79,000 lb. are in the revolving part made up of the shaft, the driver to which the field ring is attached, the field ring with its pole pieces, and the collecting rings carried upon an extension of the shaft above the driver. The speed at which the shaft revolves is 250 revolutions per minute. The lecturer attempted rather to give a comprehensive view of the whole scheme than to enter into minute technical details. He showed views of the banks of the Niagara River below the Fall, and stated that the electric car line on the American side was carried on a track supported by brackets from the cliffs, and the fare of 25 cents was the cheapest "thrill" it was possible to get.

ENGINE POWER AND SELF-PROPELLED TRAFFIC.—In the article by Sir David Salomons which we published on page 610 of our last impression on this subject the words "good road" in line 68 should be "rough road."

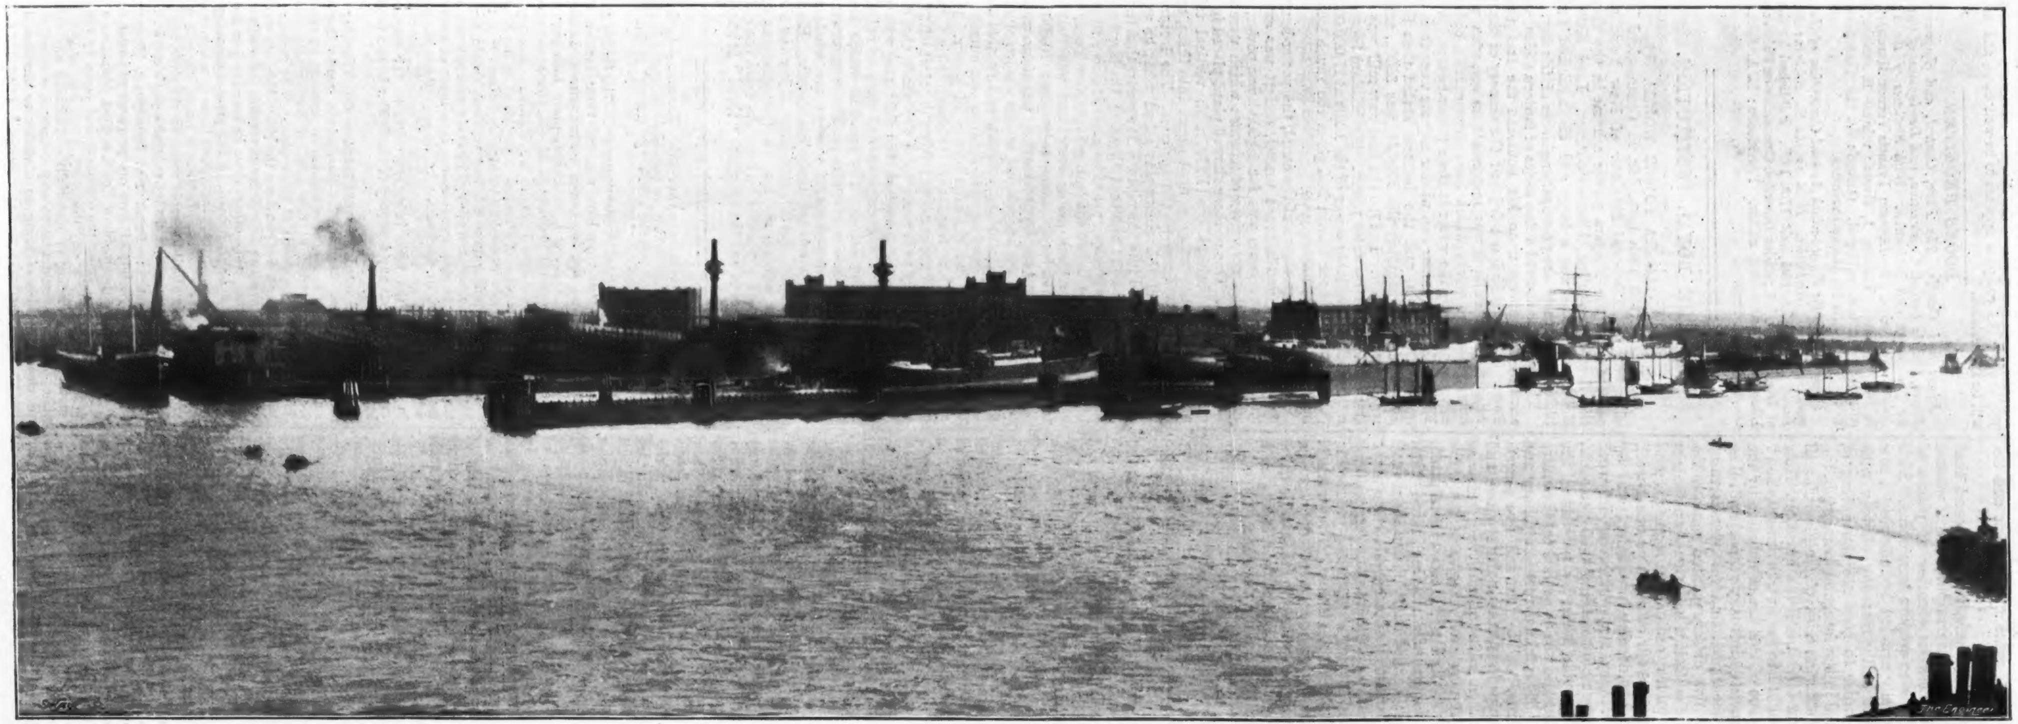
TRADE AND BUSINESS ANNOUNCEMENTS.—The Gandy Belt Company announce that they have removed their London house to larger premises at No. 97, Queen Victoria-street, London.—Mr. Charles E. Hogg, C.E., of 1, St. Helen's-place, Bishopsgate-street, sends notice of removal to offices at 34—36, Gresham-street.

A NEW METHOD FOR PULLING UP RAILWAY TRAINS, devised by Professor Koepeke, of Dresden, is employed on the Saxon State Railway, in the sidings used for making up trains. If a train or a single wagon, running down a falling gradient, should acquire too high a speed, the rails are allowed by lever action, which takes off their supports, to sink more or less in a layer of sand varying from 2in. to 5in. in thickness. Actual experience shows that a wagon or train is gradually brought to a standstill, the retardation in the case of the train being exerted on all the wagons simultaneously, without any tendency of the lighter to rise between the heavier.

OPENING TRIP OF LA MARGUERITE. — On Thursday in last week the Palace steamer, La Marguerite, made her opening run of the season to Boulogne and back. Starting by special train from Fenchurch-street at 8.35 a.m., a comfortable journey to Tilbury enabled the guests of the company to be on board shortly before 9.30. After a fast run down the river, Margate was reached about 12 p.m. With as little delay as possible those who wished to land went on shore, while others came on board to join the already large party so hospitably invited. A fast piece of steaming brought the passengers to Boulogne, where about three-quarters of an hour's run on shore was allowed. Returning home, Margate was again visited, and after an all too-rapid steam up the river, the arrival at Tilbury proved the end of a very enjoyable day's cruise.

SOCIETY OF ARTS: PRIZE FOR INDUSTRIAL HYGIENE.—The Council of the Society of Arts are prepared to award, under the terms of the Benjamin Shaw Trust, a Gold Medal, or a prize of £20. The medal, under the conditions laid down by the testator, is to be given "For any discovery, invention, or newly-devised method for obviating or materially diminishing any risk to life, limb, or health, incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known and practically available means." Intending competitors should send in descriptions of their inventions not later than the 31st December, 1896, to the secretary of the Society of Arts, Adelphi, London, W.C. The judges will be appointed by the Council. The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the judges nothing deserving the full award is sent in.

GENERAL VIEW OF THE SHIPBUILDING WORKS OF MESSRS. BLOHM AND VOSS, HAMBURG



WORKS OF MESSRS. BLOHM AND VOSS, HAMBURG.

The engravings which we publish this week of the works of Messrs. Blohm and Voss, of Hamburg, give a general view of that establishment, and also a view of the machine shop for engine work. The principle upon which both engine shops and boiler-making sheds are constructed is like those of the Vulcan Works, at Stettin, a central aisle of great height running the whole length of the building, with travelling cranes crossing it at intervals, while the side aisles are fitted up with the most recent machines for planing and cylinder boring, lathes, shearing, &c., and, in the boiler part, special machinery and hydraulic tools for bending and flanging plates for boilers. The travelling cranes have a capacity of 30 tons each. All the boilers now under construction have ends with the flange outwards, as this facilitates the riveting by hydraulic power. The butt straps around the boilers are all cut with a deeply serrated edge, thus:

It distributes the bearing of the rivets over a larger surface, and prevents the curling up of the edges of the butt-straps. All the manholes and other large apertures are punched out with a huge vertical hydraulic press. Most of the boilers which we saw were of the double-ended type, and from 60 to 90 tons in weight. They were of 1¼in. steel. The motive power for the cranes is partly hydraulic, partly electricity. The cylinder boring and planing machines were of colossal size, and suited for the construction of a much larger class of machinery than any hitherto turned out in the yard.

Horseless Carriages in France.—*Le Gaulois* of the 19th inst. states that a Parisian company has ordered from the Compagnie des Forges et Chantiers, de la Mediterranée, two hundred horseless carriages. They will be worked by petroleum, presumably benzoline motors, and are all to be delivered by the end of the year. The last-received number of the French journal *La Locomotion Automobile* gives the names and addresses of several hundreds of dealers at whose premises light oils are on sale.

THE INSTITUTION OF NAVAL ARCHITECTS.

Our report upon the proceedings of this society last week left off at the conclusion of the reading and discussion of papers in the Aula, or Great Hall of the Technical High School at Charlottenburg, Berlin. It should have been mentioned that, owing to pressure of time, the reading of the paper upon "Weakness in Tank Steamers," by Herr Otto Schlick, put down for that day, was deferred to June 13th, not, however, by any means on account of its want of interest, but because it required time for due discussion.

After luncheon a few of the members proceeded to visit the works of Messrs. Siemens and Halske, for the construction of electrical machines for transmission of power and for lighting, which are at Charlottenburg. They were received with much courtesy and shown all over the establishment. A series of gigantic dynamos, for employment in the vicinity of Johannesburg in the Transvaal, especially attracted our attention. They were intended for transmission of power to mining and pumping machinery, and this was to be distributed over an area of twenty-five miles in extent. They were of the collective force of 12,000-horse power. They had somewhat of the appearance of the large wheel-like Ferranti dynamos, which have been erected at the Portsmouth and other electrical lighting stations, but they are of far greater power, and give off a continuous instead of an alternating current, so that the employment of separate rectifiers is not required.

The manufacture of the thin sheets of insulated iron strip, of which the field magnets for these huge dynamos was composed, was very simple. Broad sheets of iron, reduced to the required thinness, were passed between smooth rollers, upon which sheets of silk paper were wound. Paste was smeared over the silk paper just before the sheet iron entered the rolls, and the insulated sheets came out on the other side, ready, after drying, to be cut up into narrow strips for the purpose required, the silk paper adhering firmly to them.

Cables and insulated wire of every kind and description were in course of manufacture at these works, both for submarine and shore purposes. The methods of insulating and preserving cables has greatly varied during the past twenty-five years. At first it was accomplished by merely squeezing the wire under an hydraulic press, through a mass of soft gutta-percha, a coating of the latter being allowed to work its way out of the aperture through which the wire was drawn, and which accordingly surrounded the wire and adhered to it. Now insulation is carried on quite differently. The wire is first of all painted with an insulating composition, coated with a preserving envelope, again painted with composition, then covered with tape, two strips of which are wound round it diagonally off a large drum, and the whole is then painted again with composition. All this is to increase the certainty of absolute insulation.

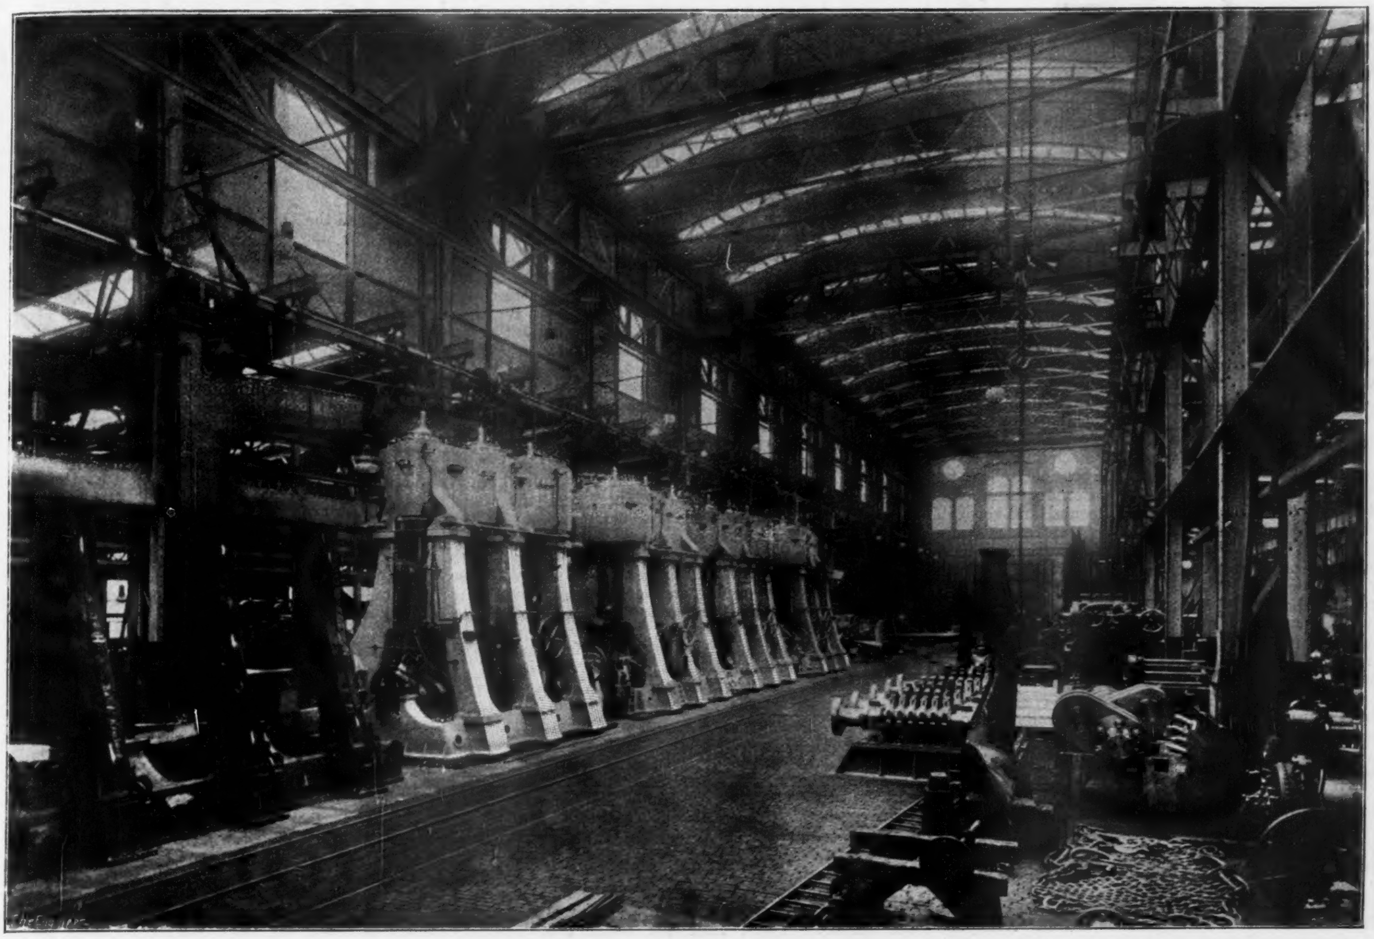
As, however, we propose to deal with the works of Messrs. Siemens and Halske separately in our columns, and to give illustrations of the various processes employed, we will now pass on to further events in the society's proceedings.

On Thursday evening the annual summer dinner of the Institution was held at the Hotel Kaiserhof, Berlin. The members of the Reception Committees at Berlin and Hamburg were the guests of the Institution. The kindly face of the Imperial Secretary of State for the Navy, his Excellency Admiral Hollman, literally shone with enthusiasm when he spoke of his personal "love of his Sovereign," whose health had been drunk with such a burst of cheering as surely never before shook the walls of the Kaiserhof Hotel. Then there was Herr C. Ferdinand Laeisz, President of the Chamber of Commerce, from Hamburg, whose courtesy and warmth of feeling had been displayed in ten thousand different acts of kindness, ever since the visitors had first stepped upon the Fürst Bismarck. Then there was Herr Kaselowski, General Director of the Berliner Maschinenbau-Actien-Gesell-schaft, who personally received us at his manufactory. Then there was the Constructor-in-Chief of the German Navy, Herr Dietrich, whose paper read in the morning had so excited and attracted our attention. Lord Hopetoun, as usual, set the example after dinner, in a few apt and emphatic sentences, of pointing to this occasion as one which went far to cement feelings of amity and friendship between two great nations. When he proposed the health of his Majesty the Emperor, alluding again to the honour that had been done to the Institution, the toast was received with unbounded applause.

After the reply of his Excellency the Minister, Lord Hopetoun, with the unanimous approval of those present, sent the following telegram to the Emperor:—"Lord Hopetoun presents his respectful duty to your Majesty, and begs to inform you that your Majesty's health has been drunk with enthusiasm." To this a reply was received by the Earl at the Kaiserhof Hotel later in the evening, which was shown to those members who were present:—"Whilst thanking you most warmly for your kind telegram, I would ask your lordship to tender my thanks to the Naval Architects, and to convey to them a most hearty welcome to my capital. I hope that the cordial reception which they have met with here has confirmed the truth of the saying that blood is thicker than water. It will, perhaps, interest the Constructor-in-Chief of her Majesty's Navy to learn that my yacht Meteor has by her fine lines beaten the Britannia by twenty-five minutes over a forty-two mile course." No opportunity was afforded to Lord Hopetoun of reading out the full text of the telegram to the assembled members till Saturday morning at the Exhibition Hall. It was there received with much applause.

The other speeches at the dinner were full of interest,

ERECTING AND MACHINE SHOPS—MESSRS. BLOHM AND VOSS' WORKS, HAMBURG



but we have no space to dwell upon them. Admiral Bowden Smith spoke as to the cordiality which had ever existed between officers and crews of German and English war vessels meeting abroad, and Mr. Dixon, in a most humorous speech, delighted them by the assurance that the Institute might expect a visit next year from its friends across the waters.

Friday was an off day until the evening, when the Institution was to have the honour of presentation to the Emperor at Potsdam. The entire morning was spent at the works of the Berlin Machine Works Company, Berliner Maschinenbau - Actien - Gesellschaft, formerly known as Messrs. L. Schwartzkopff and Co., famous for torpedoes. It is rather singular that the two great makers of torpedoes should have been "Whitehead" and "Blackhead." The work done at this factory is of the most varied and interesting character, the tools and machines employed are of the latest patterns, and they are worked by electromotors which receive power from a central station. The old shafting for steam power is still in its place in certain portions of the works, but is about to be removed entirely.

The electromotors which drive the various machines are arranged upon two different systems, according to circumstances. In some cases they are upon what is known as the "grouped impulse" system, when one motor works several machines; in other cases, the "single impulse" plan is employed. Both have their advantages. Most of the lathes, drilling machines, planing machines, slotting machines, milling machines, and other tools which we saw had an independent motor worked by power from the central station. A resistance switch with lever, which can accelerate or reduce the speed of the motor to any required extent, by putting it backwards and forwards round the periphery of a wheel, is attached to each machine. We personally tried many of these switches, and found that the control over the machine was perfect. In regard to the milling and slotting machines most of them were of duplex character, working from both ends of the beds, or at two points in a circle. We saw, for instance, as many as twelve or fourteen sets of axle-boxes for locomotives, all set end to end, being planed simultaneously, and side plates treated in this same manner. A large order for locomotives for Russia was in hand. The casings, for protecting the cylinders and cylinder gear from damage upon the rough lines employed in Russia, were very curious.

This firm is also employed in the manufacture of pumping machinery of an important character, and makes it a speciality; but the torpedo section and air-compressing machinery was that which perhaps interested the visitors most. The air-compressing engines were of the compactest make, quite different from anything that we have seen before. Phosphor bronze was the material of which the torpedoes were constructed, having a tensile strength of about 36 to 38 tons to the square inch. The engines are of the usual three-cylindered Brotherhood pattern, but there was a good deal of modification in the arrangement of the rudders and adjusting apparatus for the Schwartzkopff torpedoes, which were shown to the visitors. We observed that excessively thin discs of copper instead of india-rubber were employed in some cases for the hydrostatic valves.

The application of electromotors for the driving of machinery is, of course, quite familiar to the engineers of this country; but we do not think that in any English establishment it has assumed anything like the dimensions observable in the Berlin Machine-Works Company. But it is a question of the utmost importance. The immense rapidity of the work which has been done at Portsmouth and Chatham recently in the completion of the Prince George and other battleships has been very remarkable, and much of this rapidity has been due to the employment of electrically-worked drills, slotting machines, and other apparatus of a kindred nature.

On Friday evening a special train was provided to convey the members of the Institution to Potsdam. Here carriages were in waiting at the railway station to carry them to the palace, which was quite a short distance away. The park surrounding the latter, though very flat, like all the country in the vicinity of Berlin, is nevertheless beautiful. Groups of trees, with long avenues between them, stretching away into the distance, formed the background, as seen from the suite of magnificent apartments, and the terrace where the Emperor received the visitors at first. The Emperor did not keep his guests waiting a moment after the last arrivals had made their appearance, but, together with the Empress and the Princess of Hohenlohe, emerged upon the terrace, and after a graceful recognition of the members who stood around, the Kaiser was soon in his element, discussing shipbuilding with Sir W. White and other prominent members of the society.

As the day declined and darkness set in, supper was announced in one of the adjoining saloons, and the Empress and Princess retired, the Kaiser joining his guests in the supper room. Then the tramp of soldiers marching was heard, and a vast body of bandsmen, containing all the massed bands of the huge garrison of Berlin, was seen approaching the Palace through the great central avenue opposite the terrace. Each man was accompanied by a soldier carrying a magnesium torch; so the effect was splendid as they marched along to the rattle of drums. Then they deployed into a fan-like form around the rostrum which had been erected for the bandmaster, and a drum-major, of gigantic proportions, took up his position in front, and gave the time with his staff to the vast group of bandsmen.

Many familiar English tunes were rendered in an excellent style. But one feature particularly attracted attention. Just before the close of the military tattoo, whilst the fountains were streaming cascades of coloured light from the red fires which were burnt at intervals, there was silence for a moment. Then the Emperor bared his head, and all the vast assembly did likewise, whilst the trumpets softly rendered the old hymn, "Rock of Ages," that being now the national hymn of Germany. The roll of the drums increased in volume as the hymn proceeded, and at its conclusion, after three prolonged rattles, died gently away. Then all was over, and the tattoo was broken up. But the Emperor was not willing to see the last of his guests. When they had all been driven to the station, and the train was in readiness to depart, he drove down from the Palace and again waved his farewells from the railway platform. It was such an occasion as probably none of the visitors will witness again. We felt we were highly honoured. Not only as the members of an important scientific institution, but as the recipients of marked favour from one of the greatest sovereigns of the world, our position had truly assumed a national character.

On Saturday morning at 9.30 a m. special steamers conveyed the members of the Institution down the river Spree to the Berlin Industrial Exhibition, Treptow Park, by invitation of the President and Committee of the Representatives of Berlin Commerce and Industry. Steaming through the mercantile and business portion of the city suburbs, it was interesting to note the care observed in the arrangement of wharves and the great economy of space, land being exceedingly valuable here. On arrival in the Exhibition grounds the Institution was received in the amphitheatre by the President and Committee, and a short speech of welcome was delivered. Trade and industry recognised the influence of the Institution of Naval Architects. Perfect means of transport by sea had furthered the spread of civilisation. Lord Hopetoun replied, pointing out how shipbuilding, by spreading geographical knowledge, brought nations together; our Institution was working in that direction.

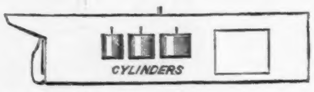
A paper was then read by Herr Otto Schlick, on "Signs of Weakness in Tank Steamers." This we publish elsewhere. It points out the fact that the position where tank steamers of ordinary construction may be expected to exhibit signs of weakness can be predicted to a nicety. It is marked in Fig. 1 with the letter A. The weakness is clearly, from its position, not due to longitudinal bending. Probably the great vibration in tank steamers has something to do with it. The paper went on to show the remedies which should be adopted.

In the discussion which ensued, Mr. Swan thought that the trouble with tank steamers had been often due to their injudicious treatment by the captains of them. Casting water adrift in the compartments was a sure way of loosening the partitions and rivets. Another speaker considered that water ballast was bad and corroded the rivets, so that they could not resist the strain and action of the oil.

Mr. Martell thought that Mr. Schlick deserved a vote of thanks for his excellent paper. It had somewhat surprised him. He was sorry that the particular vessels in which "shearing" had been noticed were not indicated. He thought that the weakness observed was due to the "panting" of the sides where vibration was greatest. The remedy appeared to be simple and should be applied at once.

Sir W. White remarked that the matter had been thoroughly taken up at the Admiralty, and the necessary calculations as to the strength of sides to resist shearing had been worked out. In old wooden ships which were subjected to great shearing strains the sides were strengthened with dowelled framing. He fully agreed with Mr. Martell that the shearing action in tank steamers was probably due to panting.

Mr. Otto Schlick, in replying, sketched the afterpart of a tank steamer upon the blackboard, showing that Mr. Martell's remark was most applicable, the position of the cylinders in these vessels—where, of course, the vibration must be greatest—being just opposite A in the figure.



Mr. Martell's paper on "Various Descriptions of Doors applicable to Water-tight Bulkheads" was then read. He considered that the question of the efficiency of water-tight bulkheads, as regards strength, was settled. The object of his paper was confined to drawing attention to the various plans which had been proposed and adopted for protecting openings through these bulkheads.

Mr. Dutton thought that the most effective form of water-tight door was not to have any at all. Mr. Gearing gave his own experience in driving a steamer across the Atlantic without permitting any of the water-tight doors associated with the engine and boiler-rooms to be opened. It was quite possible to do without them. It was merely a question of method and discipline.

Lord Charles Beresford would like if possible to have no doors at all. In the British Navy the patterns of doors could not be worse than they are, both horizontal and vertical. The belly of the ship should have no water-tight doors which cannot be closed from the deck. He agreed with Professor Elgar that a ship should be reasonably safe after a blow from a shell or a torpedo. He hoped that their able Director of Naval Construction would note what was being said.

Sir W. White said it was always a pleasure to follow Lord Charles Beresford. He should not retire from a single statement which he had made in the spring upon this subject. Since then he had had a cruise in the Channel Squadron. Naval officers generally did not share the opinion of Lord C. Beresford. At the Admiralty the best was done to meet the views of both sides—that of the naval constructor and that of the naval officer. The normal condition of water-tight doors should be closed. An imperative order to this effect has been issued by the Admiralty. A warm discussion as to this order took place. After the loss of the Vanguard voluminous experiments were made. Sir N. Barnaby invented a door which was to effect wonders. When fitted to the Inflexible it was found on a special occasion to refuse to work as a chock of wood was jammed into it. Discipline could effect more than alteration of door patterns. But, if considered necessary, why did not Lloyd's institute experiments with a view of deciding upon the best patterns?

Sir E. J. Reed said it is impossible to relieve Sir W. White from his responsibility as to the construction of water-tight doors. He must be responsible to beat down the demands of naval officers if too great. We want as few doors as possible. Lord C. Beresford should convert naval officers to a better opinion as to the consulting of their own convenience and that of their crews. We have recently received an object lesson from his Majesty the Emperor in this respect. He did not consult his own convenience last night in bidding us farewell at the station at Potsdam, when he had to be at the Templehof, Berlin, at 6 a.m.

Admiral P. Fitzgerald considered that the question was misunderstood. He utterly disagreed about converting naval officers to opinions other than their own. Naval officers must be consulted as to the arrangements of their ships; it is they who go down in the ships, not the naval architects. There is no parallel between the circumstances of mercantile steamers and those of warships.

Mr. Martell replied, and the discussion closed.

Herr F. Eickenradt then read a paper upon the "Use of Electricity on Board Ship." He considered that electricity had many advantages as a motive power on board ship, more especially perhaps as it admitted of a number of auxiliary engines placed in remote parts of the vessel, and whose connection with the boilers by pipes was most inconvenient, being driven by power from a dynamo. For ventilation, too, it was an excellent means of propulsion, as fans could be easily fitted, and heat was kept away. For winches it had already been adopted very generally with considerable success. Steering apparatus worked by a motor was difficult to arrange, but the difficulty might be got over in time.

Several speakers, including Sir W. H. White, spoke as to the value of the paper which had been read, and the writer briefly replied.

A cordial vote of thanks to Admiral Hollman and the Reception Committee was then proposed by Lord Hopetoun.

Admiral Hollman replied: "We are glad that you have found time to come over. We get the benefit of it. We are also delighted to see so many English ladies amongst us. Remember us kindly when you return home."

An excellent repast was then set before the members at the chief restaurant of the Exhibition Park, kept by Messrs. Adlon and Dressel, the Committee being untiring in their attention to our comforts. After all had enjoyed a hearty luncheon, there were the gardens and exhibition to explore. These are as yet somewhat incomplete, but promise to be a most important institution for the display of the industry and trade of Berlin later on.

On Monday morning all who had not been obliged to leave earlier started in a special train of corridor carriages, kindly provided by the Vulcan Company, for Stettin. Several representatives of the company were in the train, as well as other members of the Reception Committee, and the German Director of Naval Construction. On the arrival of the members at the railway station, Stettin, they were conveyed in special steamers at once to the Vulcan Works, and a large number of the staff of the establishment accompanied them round, explaining all objects of interest as they proceeded. The two great Atlantic liners, of 17,500 tons displacement each, were the first attractions exhibited. Then, close by them, was the keel of the new monstrous liner of 20,500 tons displacement—already rather more fully advanced than our engraving of June 12th showed—together with a considerable portion of its bracket bottom framing. The latter is about $1\frac{3}{4}$ metres in depth over the keel. Further on the visitors came to the engines for the great vessel, which are almost advanced to completion, in one of the erecting sheds. The engines for the other two liners are ready to be put into the ships.

On other building slips two large cruisers for the German Navy were to be seen in course of construction; their dimensions and various features were given in the paper read by Herr Dietrich, which was published in THE ENGINEER for the 12th of June. Three cruisers for China were also being built, and as their dimensions have not as yet been published, we will give them here. Length, 328ft.; beam, 41ft.; draught, 27ft. 7in.; displacement, 2950 metric tons; indicated horse-power, 7500; speed, $19\frac{1}{2}$ knots. Armament: three 15 cm., eight 10·5 cm., six 8·7 cm., all quick-firers; six Maxims; three torpedo tubes; armoured deck. The excessive draught will be very noticeable. After seeing the ships the visitors went through the various shops. These were fitted with the most recent patterns of milling, cylinder boring, planing, drilling, and other machines, and the sheds were very similar in plan and arrangement to the engine and boiler factory of Messrs. Blohm and Voss at Hamburg, a huge central aisle, with travelling cranes working up and down it, being flanked by side aisles for the heavy machines used in erection. The boiler-making plant was especially fine, and the arrangements for drilling rivet-holes and riveting by hydraulic power on even a more colossal scale than at Hamburg. The general appearance of some of the shops may be seen by a reference to our engravings of the Vulcan Works in THE ENGINEER for the 12th of June. The energy and enterprise displayed by this firm will be understood when we say that they have had enormous difficulties in creating a shipyard. The river is so narrow that the ships have to be launched diagonally and restrained with the utmost care, or they would in launching break into the opposite bank. The huge "liner" just commenced has a cofferdam built right out into the bed of the river around its stern. Without this a large part of the stern would be in the river.

After viewing the yard and shops, the members were driven off in carriages up to the town hall, where luncheon was served. Then, after the usual complimentary speeches, the members were again driven to the railway station, and started for Berlin, amidst a storm of cheers from our party for the directors and employés of the Vulcan Works, who were waving their farewells to us from the platform.

Thus ended the visit of the Institution of Naval Architects to Germany, a visit which was not merely an exchange of courtesies between the members of two great scientific bodies in Germany and Great Britain, but one in which our brotherhood in the great Teutonic race was emphasised by the genuine cordiality and kindness of our hosts, so emphatically, that its effects cannot fail to be lasting upon our memories and upon our hearts.

To H. E. Dr. von Bötticher, Secretary of State; to H. E. Admiral Hollman, whose genial hospitality cannot be forgotten; to Herr Dietrich, Constructor-in-Chief; to the active and energetic chairman of the Hamburg Chamber of Commerce, Herr C. F. Laeisz; to Herr John Meyer, and the directors of the Hamburg-American Line, through whose courtesy the voyage across was rendered delightful; to Herr Kaselowski, Director of the Berlin Machine Works Company; to Herr Hermann Blohm and Herr Ernest Voss; to Herr H. Stahl and the courteous establishment at the Vulcan Works; and to all who so warmly furthered the efforts of the Reception Committee our thanks are due. Lord Hopetoun's tact and his interest in all that has been going on has drawn most closely to him the respect and admiration of every member of the society. The Institution owes a debt of gratitude to Mr. S. Holmes for the pleasantest and most successful expedition that has ever been undertaken.

THE NORTH-EAST COAST ENGINEERS AT CARDIFF.

THE North-East Coast Institution of Engineers and Shipbuilders has visited Cardiff and Newport this week, in response to a very cordial invitation. This is, we believe, the first time that the Institution has gone so far south; but there is good reason for saying that the visit will be repeated. It will certainly not be the fault of their Welsh hosts if the members do not find their way again south. Nothing can exceed, indeed, the warm hospitality extended by the shipowners and engineers of Cardiff and Newport to their northern guests.

The proceedings commenced on Tuesday, when Lord Windsor, Mayor of Cardiff, invited to breakfast at the Angel Hotel the members of Council of the Institution, the Committee of Management, and a few selected guests. Subsequently Lord Windsor received in the Town Hall the great body of the members, presented by Mr. C. A. Heywood, Chairman of the Executive Committee, who made a very short and excellent little speech, in which he said that engineering and shipbuilding together had made Cardiff, and that the city was bound up in interest with the northern ports, wherever the ships were constructed that did the trade with Cardiff. Lord Windsor, in reply, said that one of the pleasantest duties of a mayor consisted in extending hospitality. He referred to the greatness of the coal industry of South Wales, and the important part which had been played by northern shipbuilders in producing the vessels which enabled their trade to be carried on. Shipbuilders would keep England in the fore front. He trusted that the visitors would enjoy themselves. He referred to the proposed visit to Newport, and he assured his hearers that there was no ground for jealousy among the Welsh ports on the Bristol Channel. Mr. Thomas Richardson, M.P., as past president of the Institution, replied. He thanked Lord Windsor for the great honour conferred on the Institution. Cardiff had been an excellent customer for the North, and he was glad to see the relations between North and South strengthened by such a visit. After a few well-chosen words of welcome from Mr. Gunn, the party proceeded to the Great Western Railway Station, where a special train had been provided to convey the visitors to Newport. The train started at a quarter past eleven, and reached the Alexandra Docks, Newport, a little before noon. The members were received, in the unavoidable absence of Lord Tredegar, by Mr. Albert Spicer, Mr. T. E. Watson, president of the Newport Chamber of Commerce, and other members of the local reception committee. The most interesting feature about the docks is the way in which hydraulic power has been used for every conceivable purpose. There are six pumping engines in various places, and these deliver water through miles of piping at a pressure of 700 lb. per square inch. The arrangements for hoisting and tipping coal wagons are extremely complete. One ship recently took in a cargo of over 11,000 tons in thirty-six hours, a feat which is, we believe, unprecedented. A number of brakes were in readiness, and conveyed the visitors, first to the works of the Uskside Engine Company, a very old place, yet turning out excellent machinery, and largely employed just now in the production of the smaller class of winding engines. Thence the party proceeded to the dry docks and shipbuilding yard of the Mordey Dry Dock Company, where there is much work in progress. Thence the party proceeded to the electric light works of the Municipality, a very fine installation, of which we shall probably have more to say. The current is supplied by five Hall alternators, each taking about 120 indicated horse-power, rope-driven each by one compound engine, by the Uskside Engine Company. The engines are compound. Steam is supplied by four large Lancashire boilers, fired by Proctor's mechanical stokers, and fitted with Meldrum's induced air current. A Worthington separate condenser deals with all the exhaust steam. Current is generated at 2000 volts, and let down on the consumers' premises to 100 volts. There are now about 9000 lights on, but the number is rapidly augmenting.

From this the company proceeded to the Tredegar Hall, where an admirable luncheon was served, and after some very short and very good speeches the whole party went on board the Lady Margaret paddle steamer, a very fine vessel of the Clyde type, and were conveyed down the Usk to Cardiff and Penarth.

On Wednesday morning the members of the Institution were conveyed by special train from Rhymney Station, Cardiff, to the Dowlais Steel Works, where about an hour and a-half was spent. The visitors were received by Mr. Martin, who is President of the South Wales Institute of Engineers. It would obviously be impossible to say much in the way of description of these works within the limits of space at our disposal. They are probably the most perfect works, taken all round, in Great Britain, and the output of the two furnaces at present in blast is largely in excess of that of any other furnaces in the kingdom. The pressure of blast is $5\frac{1}{4}$ lb. on the square inch, and the limit of output is the capacity of the men employed in charging. All the ore used is Spanish. As it is delivered in the works it is raised by water-balanced lifts and stowed in huge cylindrical bunkers. From the bottom of these it is run into the charging barrows, which are raised to the top of the furnaces by water-balance lifts. Handling the ore is reduced to a minimum, as will be understood when we say that one man deals with about 120 tons per day of twelve hours. These men are paid by the ton, and earn good wages. They are picked men. During the visit one of the furnaces was tapped, and it may not be without interest to say that not long since a steamer came in with a cargo of ore, and took away as her return cargo the same ore converted into pig iron. We have before now referred to the arrangements for handling the pig iron, and we hope to have more to say on the subject in an early impression.

From the blast furnaces the visitors proceeded to the steel works. Nothing but open-hearth steel is made, and the appliances are all the most recent and on the best principle. A 40-ton heat was tapped, and then a seven-ton ingot was taken from the soaking pit and passed on to the cogging mill, and thence to the plate mill, and rolled into a couple of large boiler plates. The rolling and cogging mill engines, by Daniel Adamson and Co., are splendid examples of mechanical engineering, and the tremendous pace at which the plate mill engines are run excited no small surprise among the visitors. We believe that they are run at the highest speed yet attained by reversing rolling mill engines of their size. They have 48in. cylinders and 5ft. stroke. All the arrangements for handling the ingots by hydraulic power are very perfect, and in many respects novel. We regret that for the moment we must rest content with this brief mention of them.

After Mr. Richardson, M.P., had expressed the thanks and gratification of the visitors in a graceful speech delivered from the step of one of the railway carriages, the train proceeded to the Bute Docks. To walk round there is to learn that Cardiff has one export trade—and one only—coal. Everything is arranged for coal. We had almost said that everything is sacrificed to it. It is not exaggeration to say that the visitors saw thousands of trucks of coal on the acres and miles of sidings awaiting shipment. As one man said, "Why they are sending Wales away." The centre of attraction was, however, the new dry dock being constructed by Messrs. S. Pearson and Co. for the Cardiff Channel and Dry Docks

Engineering Company. We have on more than one occasion referred in some detail to the improvements being effected in Cardiff. The dock in question is being constructed at the head of an artificial basin, an excellent bird's-eye view of which can be obtained from the heights of Penarth. The dock commences by a junction with the existing Roath Dock at its south-western corner. A communication passage runs from this point for about 700ft., with a width of 80ft., and for a further length of 700ft., with a width of 300ft. The level of the sill of the communication passage will be the same as the sill of the Roath Dock, *i.e.*, 43ft. 6in. below coping. The length of the proposed new dock will be 2570ft., and its width 650ft., with a depth of 46ft. 6in. below coping. The area of this dock is 42 acres, being nearly as large as the Bute East Dock, and 33 per cent. larger than the Roath Dock. The entrance lock will be 700ft. in length between the gates, its width at gates 80ft., and the remainder 160ft. wide. The length of the entrance lock will be double that of the entrance lock to the Roath Basin. The level of the sill will be 50ft. below the coping, which is 6ft. 6in. below the deepest existing sill at the Bute Docks, and 7ft. below the sill of Penarth Dock. The increased depth of sill will give a depth of 5ft. of water at low water of spring tides, and 15ft. of water at low water of neap tides, so that vessels will have little or no time to wait for the tide in entering or leaving the dock, thus saving anchoring in the roads, and avoiding necessity of waiting for higher tides. The depth of water over the sill will be 32ft. at high water of ordinary neap tides, and 42ft. at high water of ordinary spring tides. For the protection of the entrance to this dock from easterly or south-easterly winds, an embankment 1800ft. in length, forming the basin to which we have just referred, is being constructed. This embankment will make a splendid shelter, with smooth water for vessels entering or leaving the docks during south-easterly winds. From other winds the entrance to the dock will be protected by Penarth Head and the other high lands running north and west of Penarth. The entrance is situated nearly a mile below the East and West Dock entrance, and thus vessels for these docks will not interfere with those making for the other entrances to the Bute Docks. It is intended to lay out and equip the dock with all the latest and most improved machinery for dealing expeditiously with both imports and exports. The north side of the dock will be reserved for the import trade; and sufficient room will be found here to double the existing import capacity of the Bute Docks. The railway communications will be most convenient; and ample storage and warehouse accommodation, equipped with all the latest appliances, such as hydraulic machinery, cranes, and elevators, are provided for. The south side of the dock will be laid out for the shipment of coal by Messrs. Lewis and Hunter's patent coaling cranes, with the necessary sidings for continuous shipment into three or four hatchways simultaneously once vessels are in berth. The Great Western, Midland, London and North-Western, Rhymney, Taff Vale, and other railway companies have direct access to the dock, and the import traffic can be taken straight away from the dock side to any part of the country.

For the purpose of enclosing a sufficient area of foreshore to allow of the dock being constructed with the least possible delay, the embankment has been commenced, and although the work has only been started between four and five months, very remarkable progress has been made. Two lines of railway have been joined the whole way round, the length of each being more than a mile and a-half, and over a thousand tons of slag and ballast is cast out from trucks on these railways every day. Altogether, 150,000 tons have already been discharged, and it is anticipated with confidence that the embankment will be completed, and the foreshore to an extent of nearly 300 acres enclosed, in less than another twelve months. The mode of constructing the embankment is in three sections, an outer and inner bank of heavy ironwork slag, which settles down gradually in the mud, and is not easily washed away, and the centre is formed of ballast and clay to make the whole water-tight. The estimated cost of constructing the dock and embankments, exclusive of equipment, is nearly three-quarters of a million pounds.

When computing the capacity of docks for handling freight, regard must be had to the improvements which are continually being made in the means of lighting the docks, of loading and discharging and transhipping cargoes, and in other respects. For example, a steamer has taken away from the Roath Dock 9234 tons, this huge quantity being put in by several of Messrs. Lewis and Hunter's patent coaling cranes working simultaneously in the short space of twenty-eight hours. By means of hydraulic cranes very quick despatch is given to vessels arriving with cargoes of iron ore, &c. Vessels can be unloaded at the rate of 50 tons an hour per crane, and frequently vessels of over 2000 tons are discharged in fourteen hours. Since the starting of the blast furnaces of the Dowlais (Cardiff) Steel Works, iron ore arriving at the Roath Dock has been discharged, taken to the furnaces, converted into pig iron, and sent away in less than twenty-four hours. A cargo containing 1020 standards of deals was discharged a short time ago in fifty-eight hours. This is only one example of quick despatch. On the east side of the Bute East Dock a large grain warehouse, seven stories in height, has just been completed, and this building has been fitted by Messrs. Sir W. Armstrong, Mitchell, and Co. with their latest machinery for elevating and loading grain, hoisting and distributing on the various floors as required. Altogether, accommodation is provided for the storage of about 600,000 quarters of grain. The cellars of one of the warehouses at the Bute Docks, Cardiff, are used by H.M. Customs, and form the largest floor used for a bond under one roof in the United Kingdom. There is at present stored there a large cargo of rum, containing 150,000 gallons, which is being sent to all parts of the country.

The Bute Docks Company, taking into account the increasing size of vessels, are, in renewing its coal shipping staiths, making them of a greater height, so that the largest vessels may be loaded at any of them.

The cofferdam timber work of the new dock is worthy of special attention. It is one of the finest pieces of work of the kind ever carried out.

After the works had been inspected the visitors were provided with an admirable luncheon by the Cardiff Channel Dry Dock Company, and Messrs. Pearson. Mr. J. Cory, M.P., was in the chair, and some excellent speeches were made by Mr. Cory, Mr. Richardson, Colonel Guthrie, Mr. Radcliffe, Mr. Squire, and Mr. Blow. The visitors then were left to their own devices, many of them going to the Exhibition until the evening, when a smoking concert was given in the Park Hall by the President and members of the Bristol Channel Centre of the Institute of Marine Engineers.

It will not have escaped notice that we have said nothing on the subject of papers. Two, however, were read on Thursday—yesterday—forenoon, one on "The Maintenance and Repair of Marine Boilers," by Mr. J. F. Walliker, and the other on "Coal Consumption," by Mr. Fothergill. We must postpone our account of these until a future impression.

Subsequently the Barry New Dock was visited. Of this we need say but little, it has so recently been described and illustrated in our pages.

THE FOUDROYANT.

ON Saturday afternoon a number of ladies and gentlemen were taken by special steamer down the river to Woolwich, for a private view of the Foudroyant. Most of our readers have, perhaps, seen the Victory lying in Portsmouth harbour, and, if not the real ship, then the model at the Naval Exhibition at Chelsea. The Foudroyant—the Thunderer—is far more interesting than the model of the Victory, and is, indeed, in some respects more attractive than the Victory herself.

She is one of a very favourite class, a two-decker carrying eighty guns. The Victory is a three-decked ship. The Foudroyant, laid down in Plymouth in the winter of 1789, and launched in the spring of 1798, is named after and closely follows the lines of a French ship of the same name, captured by the Monmouth in 1758. She is a combination of an old and a new type. She has a lower deck extending from stem to stern, mounting thirty 32-pounder cast iron guns. On the main deck, also extending from stem to stern, she mounts thirty-two 24-pounder cast iron guns. The waist of the ship is open, and on the deck beams here were stowed all her boats and her spare spars and booms. The quarter deck extends to the open waist, and is therefore very long. On each side are mounted seven cast iron 12-pounders, on the forecastle are mounted four of the same 12-pounders, and two carronades, 32-pounders, very much out of place on the forecastle. Indeed, they were probably intended for sweeping the ship's own deck with grape, if she were boarded, or for clearing an enemy's deck for boarders in the same way. She has, furthermore, a very high poop, mounting three 18-pounder carronades on each side. The bow of the ship is very old-fashioned—much more so than that of the Victory—and the bowsprit is set with a great rake, and is provided with a spritsail yard, and carried a spritsail. Her bottom is beautifully moulded, and it is said that with a stiff breeze, all plain sail and weather sternsails, she could sail 14 knots. She was, no doubt, one of the fastest ships of the class in the world, if not the fastest.

Most old men-of-war having any spars at all, have jury masts about half the proper size, but the Foudroyant has been fully sparred, save that she has no royal masts. The enormous lift of her topsails is thoroughly French. The lower masts now in her are of iron, and rather less in diameter than the built-up wooden masts. The original mainmast was 3ft. in diameter. The rigging is all, with a very few exceptions, of hemp, and enough of her old blocks existed, or were forwarded from other ships, to suffice for her refit. She is quite sound, notwithstanding her great age, having been built of the right kind of English oak. The work of restoring her has been carried out by Mr. Shuttleworth, at Erith, Mr. Ratsey, jun., son of the eminent yacht builder, being placed in charge of the work. It has in all respects been admirably carried out, and we strongly advise all those of our readers who have the opportunity to visit the old ship.

As to how the Foudroyant got to Woolwich, we cannot do better than quote from a pamphlet supplied to the visitors on Saturday:—

"On the 11th August, 1892, there was quietly towed away from Plymouth Harbour what was, with a single exception, the most famous ship of the British Navy that has survived to the present day. A voyager down Channel, meeting the stately old line-of-battle ship in tow of a tug, travelling eastward in the glow of a summer evening, would have been reminded of Turner's "Fighting Téméraire," and have guessed that this, too, was the last voyage of a blind and helpless warrior. How vastly would the interest and pathos of the sight have been increased had he known that the ship before him had been launched in the same year as the Téméraire, that she had carried the flag of Nelson as commander-in-chief in the Mediterranean, that she had been the home of a king and queen, the latter the sister of Marie Antoinette, that to her had struck the only two line-of-battle ships that had escaped the clutch of Nelson at the Nile, and that on board her had expired a hero of the sister service, who died like Nelson in the arms of victory, the good and gallant Sir Ralph Abercromby.

"Even this, however, was not all. It would still have remained to be told that the ancient craft, freighted with so many memories, was not, like the Téméraire, passing to an honoured end on the shores she had so well defended; but that, after passing out of the hands of the Admiralty, she had been sold to a foreigner, and was on her way to a German port to close her career in exile and ignominy, forgotten by the countrymen of Nelson.

"In no other navy could a ship have been found with such a record. In no other country, it may be added, would she have been allowed to meet with such a fate.

"Happily, before her doom was sealed, the facts relating to her were made public, and it was seen that at all hazards so ignominious a fate must be averted. That a favourite ship of our greatest sea hero should come to such an end was felt to be nothing else than a national disgrace. Every newspaper in the country demanded her rescue, and Mr. Conan Doyle's spirited verses, and Mr. Linley Sambourne's cartoon in *Punch*, gave expression to the universal feeling that the Foudroyant must be saved. The Lord Mayor expressed his willingness to open a Mansion House Fund for the purpose of buying her, but time did not admit of this, and when the German owner telegraphed that the demolition had been commenced and would be proceeded with unless the price he asked were at once forthcoming, the amount was privately paid and the ship was forthwith towed back to the Thames."

It is to be noted that as a typical ship of the Nelson period the Foudroyant holds a place not second to that of the Victory herself. At the time when she was the great Admiral's flagship, the Victory was an old ship, and small for a first-rate, and only her splendid sailing qualities kept her in commission. The Foudroyant, on the other hand, was a new ship of a very formidable type, combining the fighting power of the 98-gun three-decker with the cruising qualities of the 74-gun two-decker. The 80-gun ship of 1800 occupied, in fact, the place filled by the Renown, Barfleur, and Centurion in the navy of to-day.

The following are the principal dimensions, &c., of the Foudroyant:—

	ft.	in.
Length of gun-deck	183	8½
" keel	151	5⅝
" over all	219	0
" on water-line	193	6
Breadth extreme	50	7¾
Depth	22	6
Draught forward	23	4
" aft	25	7
Height of midship port above water	5	3
Tonnage B.O.M.	2062 tons.	
Displacement, probably about..	3500 tons.	
Number of crew	713	

In about ten days she will sail for Kiel Maritime Exhibition, and subsequently she will visit Dublin and various other ports. Then once more will be seen that splendid spectacle, once so dear to the hearts of all Englishmen, a line-of-battle-ship under full sail.

ON SIGNS OF WEAKNESS IN TANK STEAMERS.*

By HERR OTTO SCHLICK, Member.

IT is generally known that signs of weakness in steamers mainly appear near the midship section, and it is generally only here that loose rivets in the butts of sheerstrake and upper-deck stringer plates, or even cracked plates appear, and this perfectly agrees with the theory of strength.

It must, therefore, naturally surprise us if analogous symptoms manifest themselves in the ends of ships in such strakes of the outside plating as are about in half depth of the vessel.

This is, in fact, frequently noticed in tank steamers. Experience has shown that in many tank steamers the riveting of butts and longitudinal seams which are situated about half-way of the depth of the hull and pretty near the after end get loose, and that in certain places the outside plating is torn right through.

This occurs with such regularity that it is possible to fix in advance the exact spot where, in the course of several years, the outside plating of certain tank steamers will tear. The place where this generally happens is marked in Fig. 1 with the letter A.

The crack at first generally becomes observable in a rivet hole, and very soon extends over the whole width of the plate. It occurs always exactly in the place where the frames change their convex shape into the concave; in other words, where they form a nearly straight line, and consequently have their greatest rigidity—see Fig. 2.

Fig 2

Fig 1.

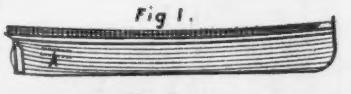


Fig 3.

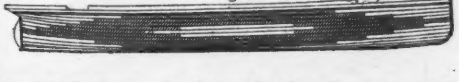


The fact that the cracking of the plates occurs at a great distance from the midship section, and that this is regularly the case in that strake of outside plating situated at about the half depth of the ship, plainly shows that we have not to deal with the tensile strain produced by longitudinal bending. One must indeed necessarily come to the conclusion that it is here simply a question of the shearing forces which occur in the longitudinal seams of the plating.

It is notorious that in a loaded girder supported at both ends the shearing forces have their greatest effect at the extremities and in the neutral axis; nearly the same applies to a ship's hull. There is only this difference, that the maximum shearing forces are not at the extreme ends, but that these take effect at a larger or smaller distance from the ends, according to the distribution of weight in the longitudinal direction, and to the fineness of the lines, but the maximum shearing strain always exists at the level of the neutral axis.

In wooden vessels it is the wrinkling of copper sheathing that shows the effects of the shearing forces; in iron or steel ships the symptoms of weakness produced by the same cause are nearly unknown, except in the cases mentioned above.

In the cases which have come under my observation the strakes of the outside plating were of an exceptionally great width—over 5ft.—and it is to be assumed that this has something to do with the cracking of the plates; for, as theory teaches us, the shearing forces occurring in the longitudinal seams gradually increase with the greater width of the plates.

Very likely the strong vibration in tank steamers helps towards the cracking of the plates. The fact that similar symptoms have not hitherto been noticed in the forepart of ships—or only to a small extent—is explained, partly by the smaller strain which occurs in the forepart of the ship, and, on the other hand, by the greater thickness of the bow-plates, which latter, in the cases considered here, are mostly thicker than usual, in order to form a strong bow against ice.

The symptoms just named in every way confirm theory, and we can conclude therefrom that it is not always permissible to leave the effect of the shearing forces entirely out of consideration, as has been generally done up till now.

Indeed, I believe that, in view of the continuous increase of the dimensions of ships, we must not, in future, neglect to give our attention to this point.

The conclusions to be drawn from these observations with regard to the construction of ships exposed to heavy strains are the following:—In the first instance, it will be useful to have the treble riveting of the butts which are situated in half the vessel's depth extended more towards the ends of the ship. Formerly double riveting was considered of sufficient strength. The extension of treble-riveted butts towards the ends will be particularly required in every case where exceptionally wide plates are used. The classification societies generally prescribe a stronger riveting of the butts whenever the breadth of the plates surpasses a certain limit.

---

*Read at the summer meeting of the thirty-seventh session of the Institution of Naval Architects, 13th June, 1896.

It is evident, however, that in doing so the prevalent intention was to avoid the diminution of the strength at the middle of the ship arising from the use of broader plates.

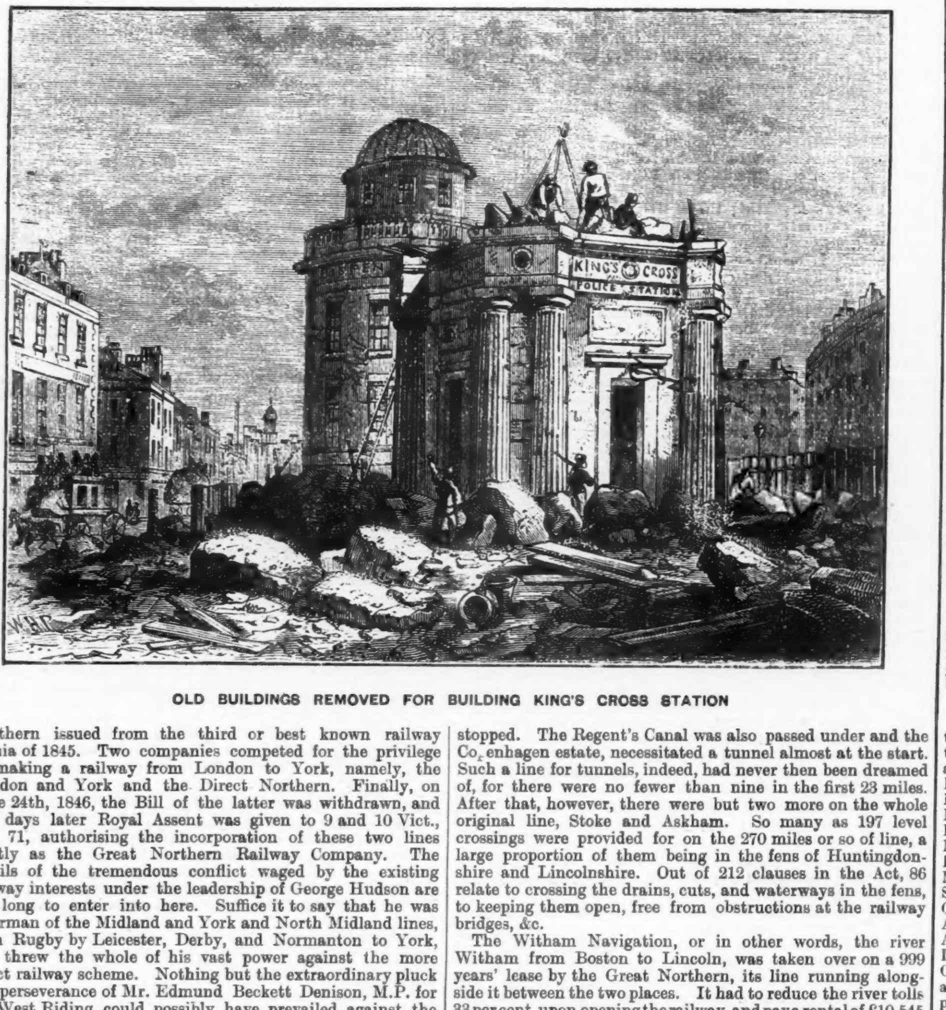
Whenever, in a ship, saving of weight is one of the most important points in the design, only single riveting for the longitudinal seams and double riveting of the butts of those strakes situated at the half depth should be permitted, but only for a certain distance in the middle of her length. But at the ends the riveting of the longitudinal seams should always be double, and treble in the butts. We further learn from these observations that it does not appear practicable to reduce the thickness of the strakes which are at half the height of the ship towards the ends. If looked upon from a merely theoretical point of view, it is advisable to arrange the thickness of the outside plating as illustrated in Fig. 3. The hatched part indicates the plates which are exposed to the greatest strain, and the thickness of which ought to be in consequence as large as possible, and the riveting as strong as possible. The doubling of the outside plating as a means for obtaining a greater strength in the direction of the longitudinal axis seems admissible only—for the reasons already given—in the upper and lower plating, because the shearing strain between two adjoining strakes of plating is here inconsiderable. At the ship's ends doubled outside plating should, as far as possible, be avoided, unless it is considered right to go so far as to apply butt straps to the longitudinal seams. I am quite aware that the object of the above considerations is neither unknown nor of great importance. I think, however, it will be of sufficient interest to be discussed here.

JUBILEE OF THE GREAT NORTHERN RAILWAY.

LIKE many other of our English railways, the Great Northern had a predecessor, although the fact is now little known. One of the products of the second railway mania, that of 1836, was a Great Northern Railway. It was to be a London and York line, constructed by Mr. Joseph Gibbs, an engineer of some note at the time. The project, however, came to nothing, and most of the money subscribed for preliminary expenses was lost. The present Great Northern issued from the third or best known railway mania of 1845. Two companies competed for the privilege of making a railway from London to York, namely, the London and York and the Direct Northern. Finally, on June 24th, 1846, the Bill of the latter was withdrawn, and two days later Royal Assent was given to 9 and 10 Vict., cap. 71, authorising the incorporation of these two lines jointly as the Great Northern Railway Company. The details of the tremendous conflict waged by the existing railway interests under the leadership of George Hudson are too long to enter into here. Suffice it to say that he was chairman of the Midland and York and North Midland lines, from Rugby by Leicester, Derby, and Normanton to York, and threw the whole of his vast power against the more direct railway scheme. Nothing but the extraordinary pluck and perseverance of Mr. Edmund Beckett Denison, M.P. for the West Riding, could possibly have prevailed against the clever and not too scrupulous Railway King.

As sanctioned on June 26th, 1846, the Great Northern was to be a line from London to York, with a loop from near Peterborough by Spalding, Boston, Lincoln, and Gainsborough to the main line again at Bawtry, and a branch from Sandy to Bedford. A sum of £5,600,000 was authorised to be raised in 224,000 shares of £25 each, whilst £1,868,000 more might be raised on mortgage when the whole of the first-named sum had been subscribed, and one-half of it paid up. This works out to about £27,660 per mile for the 270 miles or so of line just mentioned, but the sum includes the London terminus. Those shareholders who had subscribed £50 to the London and York Railway were to be given one £25 share in the Great Northern, whilst subscribers of £75 to the Direct Northern were to be credited with two Great Northern shares. Interest at a rate not exceeding 5 per cent. was allowed during construction. The original scheme, authorised just half-a-century ago, was never carried out in two important respects. The line from Lincoln and Gainsborough was not brought on to the main line at Bawtry, but more than five miles nearer Doncaster, whilst only four miles of the section between Doncaster and York were ever made. Long before the Great Northern was finished George Hudson's railway career had come to an end, and the York and North Midland had become friendly to the new-comer. Arrangements were made to run over about 10¼ miles of the Lancashire and Yorkshire from Askern to Knottingley, and over 20 miles of the York and North Midland from Knottingley to York. The latter company and the Great Northern gave each other the use of their York and Doncaster stations on easy terms. By this route the distance from King's Cross to York was 190½ miles. Many years later the North-Eastern constructed a line from near Askern through Selby to York, in virtually the course originally intended to be taken by the Great Northern. This being 2½ miles shorter, has been used by the latter ever since, and the Knottingley route discontinued for through traffic. The junction is at Shaftholme, 4¼ miles north of Doncaster. It thus happens that, after all, the Great Northern Company has never yet got to York by a line of its own, but only by running powers over other railways.

The site taken for the London establishment of the new line was in the filthy and insalubrious neighbourhood called Battle Bridge, at the north end of Gray's-inn-road. Vast mounds of ashes and rubbish, a quantity of dilapidated property of the worst class, and a couple of large hospitals for fever and small-pox rendered it a locality not fit for anything less utilitarian than a great station. From a ridiculous effigy of George IV., erected in 1829 upon the top of a police station placed at the junction of several roads—between the present Great Northern terminus and the Metropolitan station—the spot was also known as King's Cross, but the ancient name is still preserved in Battle Bridge-road, and is supposed to be of great antiquity. The Great Northern Act of 1846 appropriated the site of both the hospitals, but compelled the Company to find a fresh one not less than 1½ acres in extent for the Fever Hospital, as well as to erect a new building for it. Two years were allowed for building and handing over the fresh edifice, before ground could be broken for railway purposes. The Small-pox and Vaccination Hospital was also bought up, on similar arrangements as to time, but the Company was not compelled to rebuild it. Two large gasworks added to the delightful sights and smells of the neighbourhood of King's Cross, and much care had to be taken in making the line to prevent the gas supply being stopped. The Regent's Canal was also passed under and the Copenhagen estate, necessitated a tunnel almost at the start. Such a line for tunnels, indeed, had never then been dreamed of, for there were no fewer than nine in the first 23 miles. After that, however, there were but two more on the whole original line, Stoke and Askham. So many as 197 level crossings were provided for on the 270 miles or so of line, a large proportion of them being in the fens of Huntingdonshire and Lincolnshire. Out of 212 clauses in the Act, 86 relate to crossing the drains, cuts, and waterways in the fens, to keeping them open, free from obstructions at the railway bridges, &c.



OLD BUILDINGS REMOVED FOR BUILDING KING'S CROSS STATION

The Witham Navigation, or in other words, the river Witham from Boston to Lincoln, was taken over on a 999 years' lease by the Great Northern, its line running alongside it between the two places. It had to reduce the river tolls 33 per cent. upon opening the railway, and pay a rental of £10,545 per annum. A continuation termed the Foss-Dyke Navigation, extending to the Trent at Torksey, was also acquired on nearly as long a lease at £9570 5s. 4d. a year. Not only has the railway gained the traffic which these navigations have lost, but the latter provided the land at the side on which the line is made.

A company termed the East Lincolnshire Railway Company received its Act the same day as the Great Northern. Its line extends from Grimsby by Louth to Boston—forty-eight miles—and is leased in perpetuity to the Great Northern. This company leased the Louth Canal, which, of course, passed with it into Great Northern hands. The maximum tariff allowed to the Great Northern was 2d. per mile for first-class passengers, any portion of 6d. over on a fare calculated at this rate to be charged as 6d. Three half-pence a mile was the second-class rate, the coaches to be closed and to have glass windows. Third-class was to be one penny a mile, the vehicles to be covered and to have seats, and to be run as often and under such conditions as the Board of Trade might prescribe. Animals requiring separate vehicles might be charged 3d. per mile; sheep, pigs, poultry, fish, &c., alive or dead, 4½d. per ton per mile. The parcel rate was: under 14 lb. weight, for 25 miles or less, 6d.; if further, 1s.; not over 28 lb., any distance, 2s.; not over 56 lb., any distance, 2s. 6d.

Lines from Hitchin to Royston and from Grantham to Nottingham were also sanctioned within a month of the passing of the Great Northern Bill. Both have since been extended, but practically formed part of the original scheme.

Coming later into the field than most of the great lines, the Great Northern was able to profit by much of their experience. Its engineer was Sir Wm. Cubitt, M.P. for Andover, one of that talented family whose works will apparently endure to the end of time. The line was laid out especially with a view to high speed; and no one needs to be told how well it has answered that end. From the day it was opened throughout till now the Great Northern has been at the head of English railways for speed, two or three exceptional trains on the broad gauge hardly affecting the general truth of this. Curves, of course, were scrupulously avoided so far as possible. The hardest parts of the main line are the first twelve miles out of King's Cross, averaging 1 in 170, and about eleven more from Essendine to Stoke tunnel, at 1 in 178 to 1 in 200. The line was signalled throughout at its opening in the best possible manner, many of the signal posts being of open ironwork and great height. It was at first proposed to cross all the lines met with on the level. This was done at Newark and Retford, but not at Peterborough, where the London and North-Western branch and the river Nene happen to be side by side. The Newark and Retford crossings still exist, but it is to be hoped will be taken out some day.

The King's Cross Station was not finished till 1852, the line being opened from Peterborough to London in 1850 to a temporary station where the goods station now stands. Mr. Lewis Cubitt designed the passenger terminus, placing, as he generally did, an Italian clock tower upon the front of it. This façade, though not exactly beautiful, is well proportioned and perfectly suitable for its purpose. A very great merit of King's Cross is its ample lighting. The two long train sheds are almost wholly roofed with glass, and the large openings in the street front supply still more light. In its day King's Cross was far the finest terminus in London in every way, nor are there many which excel it now. Both spans of the roof, which are 105ft. 3in. wide, were originally supported by timber ribs formed of planks bound together, but have since been renewed in iron by Mr. Richard Johnson, the Company's present engineer. Of the engineering works on the main line the Digswell viaduct, about 21½ miles from London, is perhaps the finest. This comprises forty arches of 30ft. span, the highest about 90ft. high, the length of the whole being 1563ft. Two miles further is Robbery Wood viaduct, with seven arches 57ft. in height.

The Great Northern Company's principal locomotive, coach and wagon works have been at Doncaster from the first, the influence of Mr. Denison having easily procured that favour for his constituents. For a short time, 1848-50, whilst only some of the Lincolnshire lines were open, Mr. Edward Bury, the well-known builder of four-wheeled engines, supplied locomotive power by contract, and also acted as manager. He was succeeded, however, in 1850, by Mr. Archibald Sturrock, from Swindon, who was the first locomotive superintendent of the Great Northern. Not a little of the successful working of the line was due to Mr. Sturrock's employment of unusually high pressures of steam. He used 150 lb. from the first, at a period when 100 lb., and even less, was still very generally used.

It is impossible here to detail the growth of the Great Northern Railway from the original scheme of 270 miles to its present length—worked—of about 900 miles. It forms two-fifths of the East Coast route to Scotland, and is the shortest line from London to Leeds and the West Riding of Yorkshire. Its 8ft. engines are known the world over. By the latest returns—1894—it possessed 1015 engines, 2222 coaches, 660 other coaching vehicles, and 33,177 goods and ballast wagons. It ran over 10¼ million passenger train miles, and more than 9¼ millions with goods and coal traffic. It carried in 1894 upwards of 33½ million passengers, not reckoning season-ticket holders, and received £1,761,477 from all coaching sources. Goods and coal traffic, &c., brought in £2,408,152, and miscellaneous sources £68,344, or a total of no less than £4,237,974. The paid-up capital stood at £49,517,037. Save once, viz., December, 1856, the line has never failed to pay a dividend, which has several times been over 7 per cent. per annum, and has averaged about five. For keeping up with the times, not spasmodically but continuously, for persistent energy and "go," the Great Northern record of fifty years is a thing Englishmen may well be proud of.

INSTITUTE OF MARINE ENGINEERS.—The sixth annual dinner of the Institute of Marine Engineers took place in the King's Hall, of the Holborn Restaurant, on Wednesday evening, a company of about 300 being present, including the President (Sir Edwyn Sandy Dawes, K.C.M.G.), Sir George Nares, K.C.B., Sir James Mackay, K.C.I.E., Vice-Admiral E. Field, M.P., Lieut.-Col. Denny, M.P., Mr. T. Richardson, M.P., Mr. C. W. Cayzer, M.P., Mr. A. J. Durston, C.B., R.N., past-president, Mr. W. Ellison Macartney, M.P., Mr. W. Allen, M.P., Mr. J. Fortescue Flannery, M.P., his Excellency Commodore M. de la Camara, Spanish Naval Attaché, Mr. Duncan MacKinnon (chairman British India Company), Mr. Stewart Hall, Mr. Martin, Mr. Lind, Mr. King, Mr. G. Gomstone, Captain Chevalier Leopold Von Jedina, Austro-Hungarian Naval Attaché, Colonel Poretchkin, Russian Imperial Navy, Professor A. C. Elliott, D.Sc., Colonel Dawes, the Revs. W. D. Springett, D.D., and G. M. Capell, Captain Hodgkinson, Captain Hogg, Captain Hutchinson, Mr. C. Du Sautoy (president of the Southampton centre), Mr. A. Beldam and Mr. G. W. Manuel (past-presidents), Alderman G. W. Kidd, Mr. A. W. Robertson, Mr. W. H. Northcote (vice-president), Mr. J. H. Thomson (chairman of the council), Messrs. J. R. Ruthven, J. Richardson, U. G. Crichton, S. C. Sage, A. Campbell, F. W. Shorey, J. M. Gray, Blelloch, J. B. White, C. G. Newby, W. I. Taylor (convener), J. Adamson (secretary), and others.

RIBBED WINDOW GLASS.—The advantages and disadvantage arising from the substitution of ribbed glass for plain glass in factory windows were recently investigated for the Boston Manufacturers' Mutual Fire Insurance Company, by Mr. Charles L. Norton, of the Massachusetts Institute of Technology, says a writer in *Cassier's Magazine*. Mr. Norton points out that in both fair and cloudy weather the general resultant direction of light entering through a window having ordinary glass is downward at an angle of about 40 deg. or 50 deg. The brightest portion of the room is, therefore, the floor in front of the window. As a floor is not, as a rule, a good reflecting surface, a large amount of light is absorbed there and lost. Whatever light is reflected goes upward and backward toward the ceiling, and what light falls on the wall spaces between the windows must, therefore, be mainly light which is diffusely reflected from the floor and objects upon it. Early in the morning and towards evening the angle of the incident light with the horizontal is less, and the light, therefore, penetrates further into the room; but the wall spaces between windows gain but little by this greater obliquity. If panes of ribbed glass be substituted for the plain glass, the bright spot on the floor in front of the window disappears, and the entire floor, walls, and ceiling appear of sensibly the same brilliancy. The action of the ribbed glass appears to be prismatic, the greater part of the light falling on the ribbed glass at any point being refracted and spread out into a fan-shaped beam lying in a plane nearly perpendicular to the plane of the glass and to the direction of the ribs.

RECENT IMPROVEMENTS IN DOCKS AND DOCKING APPLIANCES.[*]

By Lyonel Clark, Associate.

(*Concluded from page* 624.)

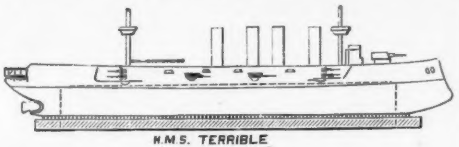
The question of bilge blocks has also had our attention. It is evident that since the ship has to be hauled on to the dock sideways, the ordinary running blocks could not be used. We have got over this difficulty by making special telescopic bilge blocks. These consist of long timbers pivoted at the centre of the dock, and supported, at a spot about under the bilge of a normal vessel, on a cast steel rack, which can be wound up and down out of a box built in the pontoon, by a worm worked from the top deck in a manner similar to the side shores. This system of berthing considerably shortens this generally rather long operation, and vessels of the largest size are completely berthed on these docks within five minutes. Other minor fittings have also had our attention, and many of the newer docks are very completely fitted with hot and cold water systems for washing down, filling, or testing tanks, &c. Hydraulic travelling cranes, capable of plumbing the ship on one side and the quays on the other, are provided on the top deck, and have proved to be of the greatest service. Indeed, we may claim that some of the most recent of our docks are as complete in this respect as they are rapid in their action, and we have been particularly fortunate in having to deal with dock owners who have been desirous of having their docks equipped in the most complete and workmanlike manner possible.

From what has been said it will be evident that I put forward the off-shore type of dock as the most perfect form of ship-lifting machine at present constructed. Its first cost is very small, owing to its lightness. [In the Appendix is given a list of various floating docks, with their weights and lifting powers.] As examples show, it can be adapted to almost any situation. It can be built and put in position with great rapidity; the Stockholm Dock, for whcih the drawings were only commenced in December last, will be at work within a few days from now. It is more rapid in its action than any other type of dock or lifting appliance known, whilst the advantageous situation in which the ship on it is placed shortens the time during which it has to remain on the dock, and still further increases its power for coping rapidly with a large fleet of vessels. Lastly, its self-docking facilities render its life, if properly looked after, practically unlimited, whilst its construction is such that at any future period it can always be extended in size, and that without putting it out of use beyond a day or so.

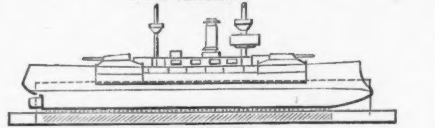
The docks described in the previous portion of my paper, although in some cases capable of lifting the smaller classes of ironclads, are primarily intended for merchant vessels. These vessels, however, are now attaining such dimensions that the step between them and even the heaviest vessels of our fleets is becoming rapidly smaller, and we have of late been repeatedly called on to design docks which in point of lifting power could deal with all but our largest battleships. The Spanish Government have at the present moment under consideration designs for a floating dock to lift ironclads up to 12,000 tons, of one of which we are the authors. This and other causes have led us of late to give a great deal of attention to the study of a dock which shall extend even to the heaviest of our battleships the many advantages of the floating type.

The problem is one that has required care and consideration, not so much on account of the mere weight of the vessels as on that of their very varied characteristics. Ordinary merchant vessels have a pretty constant weight per foot run, or unit weight, or, what comes to the same from our point of view, the shorter vessels have a less unit weight than the larger ones. Any dock, therefore, with a lifting power equal to the unit weight of the largest vessels it is built to lift, will always have a greater, or at least equal unit, lifting power when smaller ships are placed on it, so that weight and lifting power can be always equal and opposite. This is not the case with the ships of the Navy, where, on the contrary, we find that the shortest vessels have the greatest weight. To take three examples: the Terrible, of a length of 500ft., has a weight of 14,200 tons; the Magnificent, with a length of 390ft., has a weight of 14,900 tons; and the Inflexible, with a length of 320ft., has a displacement of 12,000 tons. In other words, the unit weights of these vessels vary from about 38 tons per foot in the case of the short to 28 tons in that of the long vessels.

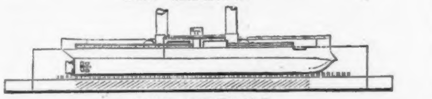
If we design a floating dock with a lifting power and length to suit the Magnificent, it could certainly equally well lift the Terrible, but the latter would overhang each end to an extent that would probably not be allowed as a general rule. On the other hand, if we built a dock long enough to take the Terrible without overhang, and powerful enough to lift this vessel, although capable of lifting the Inflexible, it could only do so by utilising large areas of the dock each end on which the ship did not bear, and which would therefore act as cantilevers and have to be connected to the body, or supporting portion of the dock, by some powerful form of construction, or a serious strain would be put on the ends of the vessel. This strain would really be greater than indicated by the difference in length of the vessels; for, especially in modern vessels, the length of straight keel, that is, that which would bear on ordinary bilge blocks, is very considerably shorter than the length between perpendiculars. An ordinary floating dock therefore would require either to have sufficient longitudinal stiffness to convey the displacement of the unsupporting portion to the supporting portion, or its unit lifting power should be equal to the unit weight of the heaviest type of vessel, merely utilising that portion which came directly under the vessel. Either of these arrangements, however, would mean a much heavier and consequently more expensive form of dock than is really necessary.



H.M.S. TERRIBLE



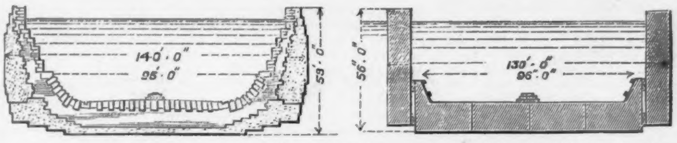
H.M.S MAGNIFICENT



H.M.S. INFLEXIBLE

The form of dock that we propose overcomes these difficulties in another manner; but, in order to make clear the reasons which have led us to adopt this design, it is well to contrast the action of the floating with the graving dock. A graving dock in its simplest form is merely a hole dug in the earth and lined with masonry round three sides and closed with a gate at the fourth. The masonry is not put in to support the weight of the ship, which may be regarded as being taken by the earth itself; but the greater part of it is merely to prevent the whole shell of the dock floating or rising from the water pressure beneath it when the pound is empty. If we always had a heavy ship in the dock the mass of this masonry might be much reduced, as the ship would counterbalance the upward thrust of the land water. Therefore we only need the mass of masonry in its entirety when the pound has to be emptied in order to get at the floor of the dock and prepare the berth. But it must be clear that as long as we can get at the floor of the dock it is indifferent to us how we do so; and, therefore, if the dock did float up when light, it would suit us just as well, providing, of course, that the shell of the dock were homogeneous enough to do so. A masonry dock could not, of course, stand this; but if we built it of iron or steel it could float without danger. Further, by constructing our invert on the cellular system, instead of making it solid, we could raise the floor above water level by merely pumping out from our cells an amount of water equal to the weight of our dock, and so dispense with the gates altogether.

But we can do better than this; for, if we construct our cells still larger, we could utilise their surplus buoyancy to support some of the weight of the vessel itself. If it were a light vessel, we should be able to lift it completely without having to use the gates at all; whilst even a heavy ship would be lightened to a proportional amount, and its draught consequently lessened. But if the draught is lessened, the height of the gates is reduced to a similar extent, and also the water pressure against them, so that they become much lighter and simpler structures. The point is, how far we can go with this surplus buoyancy of our invert without making it too large. It is interesting to note that in the case of the new docks now building at Portsmouth, if the shell were constructed of steel on the cellular principle, with the same outside dimensions as the masonry, there would be sufficient surplus buoyancy to lift the heaviest vessels of our Navy without having recourse to the gates at all. In short, if this dock were built of steel instead of stone, we should be able to utilise the displacement of what is practically a useless mass of masonry, to do away with the heavy gates, and reduce the pumping power to the strict minimum. The length of such a dock, however, would not allow us to use it for short ironclads, on account of the difficulty of giving it sufficient stiffness in the longitudinal sense, but it is interesting as showing the large amount of buoyancy wasted in a dock invert.



Transverse Sections of new Portsmouth Docks, and proposed Floating Graving Dock

We shall, however, if we examine the ships we have to deal with, find indicated the amount of surplus buoyancy that will give the best results. None of our heavy ironclads, that is, those running 38 tons to the foot, exceed a length of 400ft., and, on the other hand, the weight of none of our long vessels, cruisers or mail liners, exceeds the unit weight of the Terrible—that is, 28 tons per foot run. We should evidently therefore arrange to have a surplus buoyancy from our steel invert equal to this latter weight. In other words, we should give our dock a lifting power of 28 tons to the foot, which would be equivalent to making it the same length as that of the Terrible, and such a dock would, under these conditions, be really an ordinary floating dock without gates at either end, and we should have all the advantages of this system, and should not be restricted as to the length of vessel we could accommodate, but could deal with vessels of considerably greater length than the Terrible. Only when we had to deal with our short, heavy ironclads would the gates be required at all; but, as these ironclads would be lightened to the extent of 28 tons per foot run, that is, the unit lifting power of the dock, these gates, or rather, caissons, would be the very lightest and simplest of structures, standing barely 8ft. above the floor of the dock, and practically automatic in their action, as the dock would pick them up as it rose and leave them behind as it was lowered, whilst the water pressure against their outsides would in the worst of cases not exceed a couple of pounds per square foot. It will at once be noticed that this combination completely eliminates the need of great longitudinal stiffness in the dock. In the case of the long and lighter vessels, the dock would support them over their whole bearing length of keel, and, their unit weight and their unit lifting power of the dock being thus equal and opposite, there would be no longitudinal strains from this cause. The same will also obtain in the case of the shorter and heavier ironclads for the light caissons are not tied to any one particular position, such as the extreme ends of the docks, but slots can be fixed at various positions along the floor of the dock, and they can be inserted in that slot which most nearly approximates to the length of the vessel. For instance, in the case of the Magnificent they would be placed 390ft. apart, whilst in that of the Inflexible they would come as near together as 320ft. In this manner lifting power and weight are again kept equal and opposite, for we need only use the buoyancy of that portion of the hull of the dock which comes directly under the vessel, and make up our required balance of lifting power by utilising the displacement of the pound between the gates, which, being again equal to the length of the vessel, stills keeps our total lifting power and weight equal and opposite.

We term this combination of the two systems a floating graving dock, and we claim that it is a combination of the best points of each system. Used as a floating dock, we have, to get at its floor, only to lift by displacement the weight of the dock itself, instead of emptying the whole pound. Light ships are lifted at the expense of pumping out an amount of water equal to their own displacement, instead of having to empty the difference between that displacement and the contents of the pound. When used as a graving dock to lift the heaviest vessels a large portion of their weight is again lifted by direct displacement, and, even when the pound is called into use, its dimensions are as nearly as possible the same as those of the contained vessel, and therefore the surrounding water that has to be removed is at a minimum. Such a dock will be found to have numerous advantages. In the first place it can do all the work that a graving dock can do, and indeed more, for it is not restricted as to the length of vessels it could take in. The vessels lifted are on a raised platform, in the best of positions, well open to the air. Even when the caissons are in position this advantage is not altogether lost, as the ends are open above these low structures, and large gangways are left through the sides of the dock, giving free ingress to light and air, and affording an easy road by which to remove the different pieces that require alteration or renewal.

The choice of site for such docks is much larger, for they require no foundations, but can be put down complete in one piece in situations where a stone dock could not be erected, owing to the difficulty of keeping the site free from water. The amount of excavation is, as we have seen, less than that of a stone dock in the worst of circumstances. Such excavations, moreover, do not require to be made in the dry, but merely consist of a hole dredged out in the usual manner. They can be located as well in the water as on the land; indeed, in many cases such a position is more suitable, as the amount of dredging is reduced, and in those ports where the water is naturally deep can be dispensed with altogether. They are not tied down to any one situation, but can be moved from one port to another, if local changes render it necessary. In time of war this facility might be of special advantage. It has been advanced, in the case of the proposed docks for Gibraltar, that they will be open to the fire of the enemy. A floating dock would be in no worse position for being shelled than a stone one, but it would have the advantage that the position of a stone dock being fixed, once the range found the enemy could continue shelling it until silenced, whereas a floating dock could be easily moved from time to time, and, indeed, probably removed out of fire altogether, for it must be remembered that when the ship is once lifted, the dock will be only drawing some 15ft. or 16ft. of water. The ease with which such a craft could be moved might also be made use of for offence, for if the fleet were able to capture a port in the enemy's country, it might tow its own dock there and form a depôt in which to repair its ships, thus saving the home and out voyage.

I have already had to notice the advantage that a floating dock has, in being able to dock at all states of the tide, and not, as in the case of most of our graving docks, only able to receive vessels at high water; and I have already noted that the normal freeboard of the dock might be reduced and extra draught given if special occasion arose. I should like to most strongly insist on this point. In war time nothing is more likely than that ships will come into port leaking, down by the head, with decks nearly awash, or with a bad list. With vessels in this condition there is hardly a single graving dock in the world that is capable of receiving them. Our largest stone docks are described as having some 33ft. of water over the sill at the top of ordinary spring tides. This means that a ship of the type of the Revenge having her draught increased by as little as 6ft. could not get into the dock, even when on an even keel; and, if she were listed as little as 5 deg., an increase of draught of only 3ft. 6in. would block her, and if her heel were increased to the quite possible amount of 10 deg., a mere increase of 1ft. 6in. in her draught would make her bilge keels foul in the entrance of even our newest and largest docks, and that at high water spring tides. One can well understand that the depth of graving dock has been kept to the strict minimum. Greater depth means deeper excavation, greater water pressure, heavier inverts, and indeed increase in difficulties and in cost in every direction.

In a floating dock increased depth is obtained at the smallest of cost, and, as I have pointed out, an extra 3ft. or 4ft. could always be obtained in cases of emergency without special preparation. Similarly, in the case of a vessel with a list, nothing is more easy in a floating dock than to heel it also to the same angle, with the advantage that, ship and dock being adjusted to the same inclination, when the dock is put again on a level keel the ship also will be in the same condition. This adaptability, so to speak, of the floating dock should in itself alone be sufficient an argument in its favour, even were it replete with every other disadvantage. It is impossible to examine the disposition of most graving dock systems without being forced to the conclusion that, although capable of doing their work under normal conditions, or in time of peace, they run great risk of failing completely in time of war. At such a time what is wanted is not a dock situated at the head of a river or channel, along which the waterlogged ship, with tired-out crew and spent coal supply, would have to steam, at the eminent risk of foundering on the way, and blocking the whole navigation, to find on arrival that there is not enough water over the sill of the dock for it to enter; but a dock that can be sent to the mouth of the port or river, and receive the sinking vessel there, a dock with sufficient water over the sill to take in the largest ironclads, so long as their decks are above water; a dock with rapid pumping power, that could lift such vessels in a couple of hours, and let them be patched up and sent on to the arsenal without endangering the navigation; a dock which, when the mouth of the harbour became untenable, could be removed out of fire. For such work—and that such work will be required of a dock in time of war is indisputable—I venture to say that the floating dock is as superior to the older form of stone dock as the iron girder of to-day is to the stone arch of the last century.

Appendix.

The electric driving plant of the second North Shields Dock.—The pumps are of the horizontal centrifugal type, of 18in. aperture, eight in number, and placed at the bottom of the side of dock, close to their respective compartments. The shafts of the pump are continued upwards to the engine deck, and the electric motors drive them directly. The pumps, flyers, and shafts, run on special ball bearings. The motors are of the vertical type, one to each pump. They have a brake horse-power of sixty horses, and make 385 revolutions per minute. The motors are started and stopped by switches and regulating resistances placed in the house on the

[*] Read at the summer meeting of the Thirty-seventh Session of the Institution of Naval Architects, June 9th, 1896.

top deck of the dock, where the hydraulic valve gear is also located, so that one man controls the entire working of the dock. The generating plant is fixed on shore at a distance of some 200 yards from the dock. It consists of two sets of direct coupled inverted double-cylinder compound engines, and shut wound dynamos, giving together 850 ampères at 500 volts. Each engine is of 314 brake horse-power, and runs at 350 revolutions per minute. This plant should pump about 16,000 tons of water per hour through a mean head of a little over 18ft. The dynamos are guaranteed to have a commercial efficiency of 95 per cent., and the motors one of 90 per cent., while the loss of the cables will be under 4 per cent., so that the total efficiency of transmission will be very high.

AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

Bald tires on locomotive driving wheels.—It has been the general custom to use one pair of bald or flangeless tires on the driving wheels of locomotives with six driving wheels, and on two pairs of wheels of engines with eight or ten driving wheels; but in a discussion on this subject before the New York Railroad Club it was made evident that many roads are using or considering the use of flanged tires on all wheels of engines with six or eight driving wheels. With four pairs of such wheels, the distance back to back of wheels is usually about 53½in. for the first and last axles, and 53⅜in. on the two middle axles. This enables the engine to take curves, while on sharp curves the gauge is widened, being as much as $1\frac{3}{16}$in. wide on curves of 300ft. radius. Mr. E. E. Russell Tratman showed the varying practice on different roads. Of six Mogul engines—six drivers and two truck wheels—one had all wheels flanged, one had bald tires on front drivers, and four had bald tires on the second drivers. Of sixteen ten-wheel engines—six drivers and a four-wheel truck or bogie—five have bald tires on the second pair and eleven have them on the first pair of drivers. Of nine Consolidation engines—eight driving wheels and two truck wheels—one has bald tires on the third pair of drivers, one has them on the second and fourth pairs, two have them on the second pair only, and five have them on the second and fourth pairs. Of three twelve-wheel engines—eight driving wheels and a four-wheel truck—one has bald tires on the first and third pairs of drivers, and two have them on the second and third pairs. Decapod engines—ten driving wheels and two truck wheels—have bald tires usually on the second and third pairs. Some six-wheel switching and shunting engines have bald tires on the middle wheels, others have all wheels flanged. Eight-wheel engines—four drivers and a four-wheel truck—have usually flanged tires on all wheels, but some roads use bald tires 6½in. to 7½in. wide on the leading drivers of such engines in express service. He referred to the all-flanged eight-coupled engines of the London and North-Western Railway, and Paris, Lyons, and Mediterranean Railway; the all-flanged ten-wheel engines of the Gothard Railway, and to the ten-wheel engines of the Highland Railway, which latter have bald tires on the middle drivers.

Railway terminal at Philadelphia.—The Philadelphia and Reading Railroad some years ago replaced its passenger line on the street level in Philadelphia by a viaduct leading to the handsome terminal station on Market-street, but it has still maintained a surface line in another part of the city, which has a large freight traffic, and was originally built when this part of the city was open country. The dangers and inconveniences due to the numerous street crossings with several tracks has finally led to the adoption of a plan for lowering the railway about 25ft., and carrying the streets over it by bridges. The first work was the reconstruction of the sewer system, as many of the old sewers were too near the surface, and this work has been done by the city. The line will be about two miles long, the descent being made by a grade of 1·3 per cent., after which the grades are from level to 1 in 200, except that at the end the line rises by a grade of 2½ per cent. to the elevated approach or viaduct leading to the Market-street terminus. The branches into the yards and warehouses of manufacturing establishments along the route, including the Baldwin Locomotive Works, will be reached by inclines of about 1 in 25. There will be four main tracks, the tunnel portion being 52ft. wide, with a single arch. The open part will be 80ft. 3in. wide between retaining walls, with six tracks, columns being placed next to the outside tracks to support the plate girder street bridges, which will have a span of 51ft. 4in. between columns, and 14½ft. from columns to abutments. The headway will be 20ft. At two factories hydraulic lifts will be used instead of inclines, the lift raising a locomotive and three cars at one time. Great care has been taken in planning the arrangements for artificial ventilation, which will be by means of fans drawing air from the roof of the tunnel, and an air-supply conduit laid under the ballast. The work will cost 6,000,000 dols.

A compressed-air transmission plant.—In the construction of the Jerome Park reservoir near New York, which will cover 300 acres, and have a capacity of 2,000,000,000 gallons, the drills, cranes, pumps, &c., are being operated by compressed air from a central power station. The usual practice on contract work of this kind is to use a number of small boilers and to take little account of the fuel consumption question, but in this case a different method has been followed. In the pumping station is a duplex Ingersolt Sergeant air compressor of 600-horse power, with two tandem sets of steam and air cylinders, the steam cylinders driving a main shaft, on which is the flywheel. The air cylinders are fitted with automatic regulators, by which communication is opened between the ends of the cylinder when the receiver pressure uses alone 80 lb., the piston then making its stroke without doing any work, while the throttle valve of the steam cylinders is also closed at the same side. From the receiver an 8in. main pipe line extends with branches of diminishing size, the smallest being 1½in. diameter. A number of drills are used on the rock excavation work, and small horizontal pumps are used to pump out the trenches for the foundations of the core walls. In the erection of these walls, a number of boom derricks are used, placed in a row, and each operated by a winding engine. A branch pipe line is laid parallel with the work, and tapped for each engine, the pressure available being about 70 lb. Single isolated hoists are operated in the same way. Air reheaters are placed at intervals on the main pipe line. In spite of the leakages and losses due to the more or less rough and careless work inevitable in such a case, it is expected that a considerable net gain in cost of operating will be shown.

Pneumatic street-sweeping machine.—A street-sweeping machine, in which the dust and dirt are picked up by an air blast, is now in successful operation at Indianapolis. In external appearance it resembles a large four-wheeled wagon or cart, and it is drawn by four horses. Between the axles, and running on small wheels on the street surface, is a hood or box about 3ft. long and 6ft. wide, fitted at the front end with scrapers and wire brushes, which loosen the dirt. Behind the brushes is the mouth of the exhaust pipe, the powerful current in which draws the air and dirt up a vertical pipe, and then through a horizontal extension into a vertical cylindrical dust chamber 44in. diameter, and 40in. high, at the rear of the machine. The current strikes a baffle plate, which diverts it to the bottom of the box, where the dirt collects, while small steam jets moisten it so that it will not be drawn out by the air. The air, thus deflected and cleaned, passes out through a large pipe in the top of the box to the 12in. fan, and then down again to the hood, a hand pipe conducting a portion of the air to the furnace of the small boiler, 30in. diameter, and 5ft. high, which supplies steam for the fan engine in the front and the wagon body. Anthracite coal is used. The exhaust is turned into an iron tank, whence it passes to the jets in the dust box. At intervals the bottom of the dust box is dropped, and the pile of sweepings is picked up by a man, shovelled into a dump cart, and carried away. The machine weighs 6500 lb., or 8500 lb. with dust box full. It can clean about 1,360,000 square feet—or about thirty miles of travel of the wagon—in twelve hours. The force required consists of the cleaning machine with three horses and two men; and a two-horse wagon with one man for hauling the dirt away—or two such wagons to three machines.

A cargo unloader.—The Pennsylvania Railroad will erect at one of its freight piers on the North River a Brown double-cantilever machine for loading and unloading the freight and cargo of ocean steamers. The central supporting frame has a cantilever arm on each side, on which runs a hoisting trolley. The engine, boiler, and mechanism are mounted in a cabin on top of the machine, and all the operations are controlled by one man, who has a clear view in all directions. The lifting capacity is five tons, and the machine will handle package goods, crates, barrels, &c., and has also a special attachment for handling bulk goods, such as sand, ore, &c., and loading them into railway cars. The machine can lift five tons at a rate of 150 tons per minute, and run the trolley along the cantilever arms at 900ft. per minute, while the whole machine can move along the pier at the rate of 600ft. per minute.

LAUNCHES AND TRIAL TRIPS.

On Thursday, the 18th inst., the Brazilian passenger steel twin screw steamer Prudente de Moraes, which has been built to the order of Mr. William Brice by Messrs. Craig, Taylor, and Co., was taken to sea for her trial trip. The dimensions of the vessel are 230ft. by 33ft. by 20ft. depth moulded. The engines, which worked throughout with perfect smoothness, have been constructed by the North-Eastern Marine Engineering Co., Sunderland, and easily maintained an average speed of eleven and a-half knots per hour loaded, everything being highly satisfactory.

On Saturday, the fine new steel steamer, built by C. S. Swan and Hunter, of Wallsend-on-Tyne, for Messrs. Edmund Haslehurst and Co., of Billiter House, London, was taken to sea for her trial trip. The Claverhill is a spar deck steamer 310ft. between perpendiculars, by 42ft. by 27½ft. deep, and is designed to carry a deadweight cargo of 4600 tons; as well as a very large measurement cargo. She has a cellular double bottom throughout, and a trimming tank aft, with a complete equipment of the latest appliances for handling cargo. The accommodation for the captain, officers, &c., is in a steel house on the bridge deck, so that the whole of the bridge space is left clear for cargo or bunker space. The machinery has been constructed by the North-Eastern Marine Engineering Co., and consists of a set of their latest design of engines, with cylinders 23in., 38in., and 61in. diameter, by 39in. stroke; two steel boilers 14ft. 9in. by 10ft. long. During the construction the vessel has been superintended by Messrs. Jacobs and Barringer, of London, as well as by Captain Wigley. During the trial trip the machinery worked most satisfactorily, and after the trip the steamer proceeded direct to St. Petersburg, where she will load general cargo for Vladivostock.

On Tuesday last the new paddle steamer John Herron, which has been built by Messrs. John Scott and Co., under the superintendence of Messrs. Flannery and Sutton, of Liverpool and London, for the Wallasey Urban District Council, the launch of which we have described in a recent issue, proceeded on her trial trip on the Firth of Forth, previous to being despatched to the Mersey. The results were very satisfactory, the vessel being well within her specified draught, and attaining a maximum speed of upwards of 13 knots per hour, the machinery working without the slightest trouble. The vessel was also put to a severe test as to her steering capabilities, and proved to be exceptionally handy. The Wallasey Urban District Council were represented by the chairman, Captain John Herron—after whom the vessel has been named—and several members of the committee, who travelled up specially from Liverpool to be present at the trial, and who expressed their approval of the vessel. The smart appearance of the vessel, with the funnel amidships, and the long, airy saloons, which are tastefully decorated in carved wood and gold, were specially admired, and it is fully anticipated that this vessel and her sister boat now in progress will become the favourite vessels of this class on the Mersey.

On Monday, the 22nd inst., Messrs. Wigham, Richardson, and Co. launched from their Neptune shipyard a very finely modelled steel screw steamer, which they are building to the order of the Ungaro-Croata Steam Navigation Company, of Fiume, for their fast passenger service from Fiume along the coast of Dalmatia. The steamer is 220ft. in length by 29ft. beam, and is being constructed to take the highest class in Lloyd's register. She will be provided with very highly finished accommodation for a large number of passengers, including a handsome dining saloon and first-class state-rooms in the 'tween decks aft, with smoking room and entrance hall above them. The vessel is to be fitted with quadruple-expansion engines, self-balanced on the well-known Yarrow, Schlick and Tweedy system, which, with the boilers, are being constructed by Messrs. Wigham, Richardson, and Co., to give a speed of 15 knots per hour. Amongst the company present at the launch were Mr. and Mrs. Dendy, Mr. Mouton, superintending engineer, and Captain Baccarcich, representing the Ungaro-Croata Steam Navigation Company, and Mr. Alexander Rolland, Mr. Richardson, Mr. Christie, and Mr. and Mrs. Tweedy. As the vessel left the ways she was named the Pannonia, the ceremony being gracefully performed by Mrs. Dendy, of Newcastle-on-Tyne.

On Friday, the 19th inst., the s.s. Oilfield was taken to sea for her trial trip. This vessel is one of the most modern type of oil tank steamers designed and constructed for carrying oil in bulk, and represents the latest outcome in experience in the special trade. During a series of runs over the measured mile with several of her oil compartments filled, she attained a speed of nearly 12 knots per hour. She has been built by the Tyne Iron Shipbuilding Company, of Willington Quay-on-Tyne, for Messrs. Hunting and Son, of Newcastle-on-Tyne, and is the third steamer which this firm has built for this special trade. She is divided into small compartments, and is designed to meet the requirements for steamers carrying petroleum in bulk through the Suez Canal. She has a most efficient double system of pumping machinery so as to provide against possible contingencies, has the electric light fitted throughout, and special arrangements for ventilating and cleaning her oil compartments. She is over 355ft. in length, 47ft. in breadth, and carries nearly 6000 tons on a very light draught. Her engines are 27in., 44in., 71in., by 48in., with three single-ended boilers, and have been constructed by the Wallsend Slipway and Engineering Company, of Newcastle-on-Tyne. At the trial were present the owners and many of their friends, together with Mr. Taylor, inspecting engineer, and Captain Brunton, under whose superintendence and inspection the vessel has been built.

On Saturday morning there was launched from the shipbuilding yard of Messrs. C. S. Swan and Hunter, of Wallsend, a fine steel screw steamer, built to the order of Mr. W. R. Rea and Mr. Charles M. Legg, of Belfast. This steamer is of the partial awning deck type, with long full poop, raised quarter-deck forward, and top-gallant forecastle, thus improving upon the common design of these steamers, with a view to obtaining more measurement space at the after end of the vessel, and to ensure her trimming better when loaded with homogeneous cargo. The steamer has a cellular double bottom throughout the length for water ballast. She will also be fitted with powerful steam winches, as well as steam steering gear, steam windlass, &c., all by the best local makers. The dimensions of the vessel are:—312ft. between perpendiculars; breadth, 41ft.; depth, 23ft. 1½in. moulded; and she has been designed to carry deadweight cargo of 4350 tons on a moderate draught, as well as an unusually large measurement cargo. The machinery is being constructed by the North-Eastern Marine Engineering Company, of Wallsend, and consists of a set of their most recently designed engines, with cylinders 23in., 38in., and 61in., by 39in. stroke; two steel boilers, 14ft. 9in. by 10ft. During the construction the steamer and machinery have been superintended by Mr. Joseph Lewis, of Belfast, on behalf of the owners. On leaving the ways the vessel was named the Thornley by Mrs. Rea, who, together with Mr. Rea, travelled especially from Belfast for the purpose.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

In the finished iron trade the home consumption appears to be extending, and shipping houses are inquiring for heavy supplies. Best bar makers are doing a steady trade at £7, and for merchant bars there is a fair inquiry at £6 5s. The manufacturers of common bars have more work in hand at £5 7s. 6d. upwards, £5 15s. being the maximum. The high price of spelter continues to assist to strengthen the prices of sheets. June deliveries were quoted to-day—Thursday—in Birmingham at £19 2s. 6d. per ton, and forward deliveries £18 17s. 6d. The German galvanised sheet makers are declared to be getting their spelter at £1 per ton less than their English *confrères*, and their black sheet iron at also £1 per ton less. This handicapping has not yet much affected the English trade; in fact, British makers were never before sending away so much iron as now. But if the differences noted are maintained, they cannot fail to tell by-and-bye. In this district some merchants are already placing orders for galvanised iron for export with Germany instead of at local works.

Owing to the interference with the running of the mills by the hot weather, sheet iron makers cannot deliver orders to customers as rapidly as desired. £10 7s. 6d. to £10 10s. is quoted for ordinary brands of galvanised corrugated sheets of 24 gauge, delivered Liverpool, but superior brands are quoted £11 7s. 6d. to £11 10s. Black sheets are quoted £6 15s. to £6 17s. 6d. for doubles and £7 15s. for lattens.

This week certain of our iron and steel firms report the receipt of orders on Japanese account for iron and steel, in the form of bars, sheets, and hoops, and contracts for railway bridgework, railway fastenings, and allied material have also of late been received. The orders are being placed through the London agents of the Japanese Government. One train load of iron and steel was despatched last week. Some of the contracts have been secured in competition with Belgian and German makers, and early delivery is pressed for. Much of the bridge and railway work will be put together in Japanese yards.

In the pig iron trade demand is well sustained, and prices are kept steady by the limited make which still prevails. Northamptonshire forge pigs are quoted 41s.; Derbyshire, 41s. to 42s. 6d.; and Lincolnshire forge, 44s. net at stations; Northamptonshire foundry metal No. 3 is 43s. 6d. to 44s., and Derbyshire, 45s. 6d. to 47s. 6d.; Staffordshire cold-blast all-mine pigs are quoted 92s. 6d. to 95s.; hot-blast all-mine 55s. to 57s. 6d.; part-mine, 42s. to 45s.; and cinder, 35s. to 38s. At current prices orders will be accepted for delivery three and six months forward.

Steel in the form of tin bars and blooms and billets is in many instances still superseding pig iron in this district, as a raw material for the mills and forges in a manner which evidences to a certainty that consumers will never go back to the old material. They find steel, as now produced at the great works, so eminently suitable for rolling down in the iron mills for the manufacture of sheets, hoops, strips, small rounds, &c., that the saving on the puddling process is very considerable. Tin bars and billets were quoted to-day £4 5s. to £4 7s. 6d., and some sellers even talked about £4 10s. to £4 12s. 6d. Steel joists, of 10in. or 12in. by 6in. in size, the produce of Scotch mills, were quoted £5 17s. 6d. in good quantities, with more money for small lots; tees, ordinary sections, were £6 7s. 6d. upwards, and angles of approved specifications, £5 12s. 6d. Bolckow, Vaughan, and Co.'s steel plates for engineering purposes were £5 15s. and upwards, delivered in Midlands, and boiler plates, £6 5s. The Lilleshall Steel Company, Shropshire, quoted steel wire rolls, No. 6 and upwards, £5 15s.; plating bars, £5 5s.; and round and square, up to 2in., £5 15s. Cold-rolled and close annealed working-up steel sheets, the products of local mills, were quoted on the basis of £9 5s. to £9 10s. for singles.

The local coal trade is disturbed this week by the unsettled state of the Conciliation Board question, and the fervent hope is expressed that the difficulties which seem to be ahead may, by the exercise of mutual forbearance and caution, be if possible averted.

On Tuesday a large gathering of representatives of the cycle industries attended at the Holford Works of Messrs. Accles, Limited, Birmingham, to witness experiments in the new lu-mi-num metal, which it is claimed will supersede steel. The metal consists of 96 per cent. of aluminium and four of alloy. Cycle frames are cast complete in tubular shape without joints. The tests show the tube could withstand pressure of 3000 lb. without deflecting. The metal, which is incorrodible, is of equal strength to best wrought iron, but only one-third the weight.

The Staffordshire Institute of Iron and Steel Works Managers have just paid a visit to Woolwich Arsenal, the occasion being the annual excursion of the Institute. After inspecting the magnificent engine plant, the party had the privilege of witnessing the various processes of the manufacture of heavy guns. On all hands were to be seen ponderous armament, the heaviest being the 110-ton and 67-ton guns, the former of which is not now manufactured. A large number of the new 47-ton quick-firing breech-loaders were in course of construction, the special feature of these pieces being the wire lining introduced only two years ago. Each of these guns is bored out of solid cast steel, and is fitted with two cases, the inner one of which is encircled with about 13½ tons of wire, for the purpose of imparting additional strength to the weapon. Among the objects of special interest in this department were a 40-ton hammer, capable of striking a blow of 1000 tons, and a radial crane possessing a lifting power of the same tonnage.

The fact that there has been no boiler explosion at any works in the South Staffordshire district for a period of about eighteen months goes to show that local steam users generally are exercising careful supervision. There are, however, people who still manifest indifference, which might, if not carefully watched, bring about very regrettable results. In the report of the Chief Inspector of Factories and Workshops for 1895, it is narrated that one man bought a boiler and 4-horse engine for £10, including erection. Neither the man nor his employés knew anything about boilers, and no proper advice was obtained in the matter. The natural consequence was an explosion, killing one young person and injuring two men. Another boiler was found working minus water-feed, water gauge, and steam pressure gauge. The boiler is filled from the manhole, which is then screwed down. The safety valve is regulated by weights on a long lever, and from the time the fire is lighted there is no indication of the water or the pressure of steam.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—Except that the general activity throughout the engineering and iron-using industries does not bring about a corresponding improvement as regards prices, for raw and also for manufactured material, the position, taking it all through, continues satisfactory. As I have pointed out previously, the enormous means of production are more than sufficient to keep pace with any possible demand for home consumption, and no matter how active the iron-using trades of this country may be, unless a foreign outlet can be found for a large proportion of the production of raw material, excessive supplies will cause keen competition for business, which necessarily keeps down prices at a very low level. The result is that whilst the engineering industries are almost as busy as they possibly can be, makers of pig iron are unable to command any very remunerative prices for raw material; much the same applies to steel, both in its raw and manufactured condition, but finished iron is beginning to benefit from the activity in this branch of trade on the Continent, which is enabling English makers to export considerable quantities where they have hitherto been kept out by foreign competition.

A generally healthy tone characterised the Manchester Iron Market on Tuesday, and there was a full average attendance, with a fair inquiry both for raw and manufactured material. For pig iron a moderate demand comes forward, with prices steady at about late rates. Local makers are very firm at their full list rates, and are booking a tolerable weight of orders both in foundry and forge numbers. Some fairly good inquiries are stirring for forge Lincolnshire, and although the recent advance of 6d. per ton has not in all cases been made the official list price, it is quite exceptional where makers are now quoting under 41s. 6d., and one or two moderately large offers, based on the old list rates of 41s. net cash, delivered Manchester, have been declined. The Warrington forges especially are inquiring for considerable quantities, with about 41s. 2d. as the basis on which they are prepared to place orders for delivery in that district. Both Lincolnshire and Derbyshire foundry qualities remain firm at late quotations. Outside brands offering here are not appreciably affected by the further giving way in warrants, but there are low sellers of Scotch, with Middlesbrough not quite so strong as it has been. Makers' quotations, however, remain at about 45s. 10d. to 46s. 4d. for good foundry Middlesbrough delivered by rail Manchester, with Eglinton 46s. to 46s. 6d. delivered Lancashire ports, and 48s. 3d. to 48s. 9d. delivered Dock Quays, Manchester, and Glengarnock about 6d. to 9d. above these figures.

Manufactured iron makers are all full of work, and report new orders coming forward in increasing quantity, with a fairly good foreign trade being put through, owing to the advance of prices on the Continent. Lancashire bars have in one or two cases been advanced 2s. 6d. per ton, and £5 10s. to £5 12s. 6d. are now the general quotations, with North Staffordshire bars also hardening, and only in special cases to be bought under £5 12s. 6d. to £5 15s., delivered here. Sheets are firm at £7 5s. as about the minimum, and hoops at £6 2s. 6d. for random to £6 7s. 6d. for special cut lengths, delivered Manchester district, and 2s. 6d. less for shipment.

A fair business is stirring in the steel trade, with no change in prices. Hematites are firm at 57s. 6d. to 58s., less 2½; ordinary steel billets remain at £4 7s. 6d. net cash; boiler plates £6 5s.; any attempt to get more than this generally results in orders going elsewhere, whilst local-made steel bars, although quoted £6, might be bought at a trifle less.

The metal market continues strong, with an active demand for all descriptions of manufactured goods, at the advanced rates quoted last week, which have been readily got by manufacturers.

The activity which I have reported recently throughout the engineering trades is not only fully maintained, but in most of the leading branches new work comes forward in increasing quantity, until it is now with many of the leading firms more a question of delivery than of booking orders. Some of the tool makers, who have, perhaps, not been so full of work for many years past, are quite unable to book further orders, where anything like early delivery is required. Locomotive builders are also in much the same position, and are supplied with orders, both on home and foreign accounts, to keep them fully going over the remainder of the year, whilst new work still comes forward steadily, the Vulcan Foundry Company, of Newton-le-Willows, having during the past week booked sixteen heavy goods engines for the East India Railway. Boiler makers, are not perhaps getting quite so much work as a short time back, but are all still well engaged. Stationary engine builders, although they have no great pressure of work on home accounts, are very busy on orders for India, China, and Japan, the two last-named countries being just now much more important customers than India, and a good deal of heavy engine plant is being sent out, connected with the equipment of new mills, whilst the rapid development of the textile industry both in China and Japan has also placed large orders for machinery in the hands of local machinists, who are full of work for a considerable time ahead.

Messrs. Holden and Brooke, of Salford, have just completed an installation for heating the Manchester General Post-office, which is on rather novel lines. Hot water is forced through the entire building by means of four "exhaust" injectors, which are worked by the exhaust steam from either the electric light or pneumatic engines. The system has, I understand, been patented by Mr. Brooke, and was worked out in conjunction with Mr. J. W. Curra, of the Engineering Department, St. Martin's-le-Grand. It may be added that the injectors in question supply twenty-eight different circuits of heating pipe, the quantity of hot water supplied to each circuit being independently controlled by the man in charge, without interfering with the working of the injectors, or the quantity of water passing through the other pipes.

I had an opportunity the other day of inspecting the new electric lighting installation which has been put down throughout the Manchester and Salford Docks of the Ship Canal. The previous system for lighting the docks was to a large extent only of a temporary character, and was split up into three temporary stations, with portable engines, which proved to be not only expensive but inefficient. Acting upon the strong recommendations of Mr. Hunter, their engineer, the directors have at length decided to face the expenditure required to place the electric lighting on a permanent basis, in one central station, and this work has now been completed, with the result that nearly double the light is now obtained, and it is hoped that there will be a considerable reduction in the working expenses. The plant for the new electric installation includes two sets of 100 brake horse-power inverted cylinder engines by Goodfellow, of Hyde, and two sets of 30 brake horse-power similar engines by Browett and Lindley, of Patricroft, the engines being each fitted with ejector condensers. The lighting area includes the Manchester and Salford Docks, the Mode Wheel Locks, and the whole of the dock sheds and offices. The previous electric lighting consisted of 66 continuous current arc lamps. These have now been supplemented by 28 alternating arc lamps, 100 thirty-two-candle power, and 28 sixteen-candle power incandescent lamps, the latter being used entirely for lighting the offices and sheds, and this portion of the work has been carried out by Messrs. Baxendale and Co., of Manchester.

Another important addition to the equipment of the Manchester end of the Ship Canal is the additional hydraulic power put down for working the gradually increasing number of hydraulic cranes, and for operating the locks and bridges, which has become necessary owing to the steadily enlarging volume of traffic. At Mode Wheel supplementary hydraulic plant is being put down consisting of two sets of inverted cylinder jet condensing triple-expansion engines, each capable of giving off 20,000 gallons of water per hour at forty revolutions per minute, with a boiler pressure of 160 lb., supplied by the Glenfield Co., Kilmarnock. The steam power is supplied by a couple of steel Lancashire boilers 8ft. diameter, and 30ft. long, made by the Oldham Boiler Works Co. The boiler feed pumps have been supplied by Messrs. Frank Pearn and Co., and there are also two sets of horizontal duplex pumps for pumping water from the canal to the supply tank.

All descriptions of round coal remain in much the same depressed condition as reported last week. In the better qualities suitable for house-fire purposes heavy stocks are accumulating at most of the collieries, notwithstanding very few of them are working more than three to four days per week. Prices are without quotable change, but where business is concerned the tone is weak, and extremely low figures are taken to effect clearance sales, many of the collieries having a very large number of wagons under load at the sidings. Common round coals continue plentiful, and low in price, notwithstanding fairly large requirements for iron-making, steam, and general manufacturing purposes; and for ordinary steam and forge qualities not more than about 5s. 6d. to 6s. is being got at the pit mouth. The gas coal contracts for the ensuing season are now being gradually settled, and the general basis of prices is quite 3d. under last year's rates, the better qualities, in some instances, having been offered at extremely low figures. At the pit mouth ordinary Wigan 4ft. gas coal would seem to average about 6s., and ordinary Arley gas coal 6s. 9d. to 7s. per ton. As regards engine fuel, the limited supplies now offering move away readily, and in most cases colliery owners have no difficulty in getting some advance upon recent quotations, representing generally about 3d. to 6d. per ton. At the pit mouth, 3s. 3d. to 3s. 9d. are about the average figures for common, and 4s. 6d. to 5s. for better qualities of slack.

Rather more business is being done in the shipping trade, chiefly in the medium qualities of house coal for Ireland, but steam coal continues difficult to sell, and quite as low in price as ever.

Barrow.—The market for hematites in the West Coast district is unaltered, and makers are still busy on orders placed some time ago, while reporting a brisk inquiry at the immediate moment for forward as well as for prompt deliveries. Prices are, however, weaker so far as warrant iron is concerned. Sellers are doing business at 46s. 11½d. net cash, and buyers are offering 46s. 10½d. Makers, on the other hand, quote 48s. to 49s. per ton for parcels of mixed Bessemer numbers net f.o.b. During the week two furnaces have been blown out—one in Furness and the other in Cumberland, and there are now thirty-seven furnaces in blast, as compared with thirty in the corresponding week of last year. Stocks again show an increase this week to the extent of 950 tons. There is now in hand 314,093 tons, or an increase of 24,917 tons since the beginning of the year.

Iron ore is in rather smaller request consequent on the blowing out of furnaces, but prices are steady at 10s. per ton for ordinary sorts net at mines, best descriptions ranging up to 14s. 6d. per ton at mines. Spanish ores of 50 per cent. quality are at 12s., and 60 per cent. at 12s. 9d. per ton net at West Coast ports.

The steel trade is very briskly employed. The activity in the rail trade is very marked, and makers have not only secured good orders, but are in receipt of inquiries which justify hopes of a continuance for some months to come of the present run of activity. There is also a very steady business doing in steel shipbuilding material of all sorts, and the market is especially firm in plates and heavy steel castings. All other branches of the local steel trade show life.

Shipbuilders and marine engineers are busy, but report no new orders. The Powerful, first-class cruiser, was on view last week at Barrow in aid of the local charities, and £249 7s. 8d. was realised. This cruiser is now ready for delivery to the Admiralty, and is waiting for a navigating party to take her round to Portsmouth.

The coal trade is quiet, and the coke trade is a shade weaker.

Shipping shows an improvement. The exports of pig iron from West Coast ports during the past week amounted to 7790 tons, and steel to 11,655 tons, as compared with 3235 tons of pig iron, and 6897 tons of steel in the corresponding week of last year. The aggregate shipping returns this year so far show 147,752 tons of pig iron, and 226,054 tons of steel, as compared with 126,748 tons of pig iron, and 170,799 tons of steel in the corresponding period of last year, an increase of 21,004 tons of pig iron, and 55,255 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

QUIETUDE still marks the coal trade, with very little prospect of change either in manufacturing or household fuel. Various disputes are still dragging their slow length along at district collieries, and neither side appears particularly anxious for a settlement, as there is not any sign of a concession being made with that view.

The miner's union is actively supporting the men, and as trade is so very quiet, the miners find very little choice between "playing" with the union allowance and endeavouring to resume work for two or three days a week. As it is, with the diminished employment, household fuel is accumulating in almost all directions, while steam coal is more abundantly brought to bank than there is any likelihood of its being used. A small tonnage is being sent by rail to the metropolis, where the demand for inland coal is still further attenuated by the low rates charged from Cardiff and the North of England. A fair tonnage of South Yorkshire coal is being taken to the Eastern Counties, and a good demand for steam coal is still reported for the Humber ports, with the exception of Grimsby, where a decrease is exhibited. Although the quotations remain unchanged the tendency is undoubtedly downwards. Best Silkstones make from 8s. to 9s. per ton; secondary qualities from about 6s. 9d. per ton upwards; Barnsley house, 7s. to 8s. per ton; thin seam coal from 5s. to 6s. per ton. Steam coal, Barnsley hards, is purchaseable at 6s. 6d. to 7s. per ton; Parkgate and secondary qualities making from 5s. 9d. per ton. Gas coal is rather quiet at prices previously quoted. The Gas Committees of several corporations, with a lively recollection of what took place in 1893, have been asking the gas companies to consent to what is called the strike clause in their contracts. The effect of that clause is in the event of a strike occurring to make the colliery owners responsible for maintaining supplies to the extent at least of all the surplus coal on the pit banks. The suggestion has not been favourably received, and several coalowners have consequently refused to contract. An improvement in trade is shown in the demand for small stuff for coking purposes. In these qualities values are firm, and in several instances rather higher terms are obtained. Small nuts make 4s. 3d. to 5s. per ton; screened slack from 3s. 3d. per ton; pit slack from 2s. 6d. per ton; smudge from 1s. to 2s. per per ton, all at the pits. There is a better demand for coke in spite of the increased output from the new ovens. Values remain firm at 8s. 6d. to 10s. 6d. for ordinary qualities, up to 12s. 6d. for the highest grades. Although there is some anxiety as to the action which may follow the conference between the coalowners and the miners' leaders, very little doubt is entertained that the present condition of affairs will continue without any active hostility over the general coalfield.

In the pig iron trade there has been a distinct improvement following the lull of the last two or three months. Several heavy purchases have been made, covering periods as far forward as the beginning and the middle of 1897. An increasing desire to cover requirements for the next half-year, if continued, is certain to bring about a further stiffening in prices. Already in one or two instances local makes have been advanced 6d. per ton for future deliveries. There is a little more doing in railway material, which in its turn has affected the business in bar iron. Prices are as follows:—Hematites, mixed numbers, East Coast, 53s. to 53s. 6d.; West Coast, 57s. to 57s. 6d. At these quotations, which are delivered in Sheffield, a brisk business in proceeding. Derbyshire foundry, No. 3, 41s. 6d.; No. 4 forge, 37s. 6d. to 38s.; Lincolnshire forge, 39s.; foundry, No. 3, 41s. to 41s. 6d.; bar iron, £5 5s. to £5 10s.; sheets, £7 to £7 10s.; steel boiler plates, £6 5s. to £6 7s. 6d. An active business is reported in crucible steel, which is stated to be more briskly called for than at any time during the last sixteen years. As a result, competent steel melters are being wanted. Much of the steel thus called for is used up in the cutlery, edge tools, and file branches. The engineering establishments of the country are also making heavy demands, and the call from abroad is unusually important. As a consequence, the rolling mills, although not all fully occupied, are much better off than they were a month ago.

The thirty-second annual report of Messrs. John Brown and Co., Atlas Steel and Ironworks, Sheffield, is very satisfactory. The directors state that the improvement in the trade of the country has had a most beneficial effect on their general business, the various departments producing railway and shipbuilding material having done better than for several years. The armour-plate department has been well employed. The large expenditure recently incurred has enabled the company to execute all orders received for armour without difficulty; but the directors add that the means of production of armour in this country have so much increased that unless large orders are shortly placed it is feared this department will not be fully occupied. The output of the collieries has been considerable, but, owing to the competition of other districts, the price has been so low as to be almost unremunerative. Two of the seams at Car House could only be worked at a loss, and have, therefore, been closed. The directors add that the prospects generally of the South Yorkshire coal trade are at present exceedingly gloomy. The net profit of the year is £122,368 5s. 9d., out of which it is recommended that £25,000 be added to the reserve fund, which will then amount to £225,000, and that a dividend should be paid on the ordinary shares at the rate of 7½ per cent. per annum—as compared with 5 per cent. last year. A balance of £35,385 is carried forward. Lieut.-Col. Davies—late R. E.—has been appointed to fill the vacancy on the directorate caused by the death of Mr. H. D. Pochin.

Messrs. Thos. Stainforth and Co., Hackenthorpe, near Rotherham, are directing attention to Helliwell's patent safety appliance for shafts and pulleys, of which they are sole proprietors and manufacturers. They have this invention at their own establishment, and it is also in use at the Master Cutler's Works—Messrs. John Henry Andrew and Co., Toledo Steel Works, Sheffield. Captain Smith, Chief Inspector of Factories and Workshops, strongly recommends the appliance, for which it is claimed that when fixed it is impossible for any person, or for their clothes, to get caught with either the shafting or by the arms of the pulleys. As these are two main sources of danger and cause of accidents, the makers claim that the appliance renders all pulleys and shaftings quite safe, and thereby ensures immunity from accidents, besides effecting a saving and economy in belts. It can be easily adapted to any horizontal, vertical, or oblique shafting, in any situation, either on the floor, ceiling, or walls. "The very large number of fatal and other accidents caused by revolving shafting," says the chief inspector, "has always been a serious consideration," and he reports to the Home Secretary that the appliance invented by Mr. Halliwell for the fencing of shafting and drums would, if adopted, "save many lives."

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

WHILE almost all branches of the finished iron and steel industries and also the allied traders are showing improvement, and manufacturers speak cheerfully of their prospects, the pig iron market is dull and unsatisfactory, and prices are easier, not because of any change for the worse in legitimate trade, but because of the speculative operations in Glasgow. All the favourable statistics, the active deliveries, and the decreasing stocks go for nothing in face of a fall in warrants, however such fall may be brought about. It appears strange that Cleveland, which makes three times as much pig iron as Scotland, should be ruled by the latter in fixing the price of its iron. But Cleveland iron is not so much of a medium for speculation as Scotch, though it has to a great extent to follow the fluctuations in the latter. During the last few days the "bears" have been endeavouring to "cover," and to do this on the best terms they have been doing their best to force down prices, effecting this by offering small lots of pig iron at low prices, and this causes disquietude among the weak holders of warrants, and impels them to clear out. Ordinary consumers will scarcely buy at all in a drooping market, so that very little has this week been done in the way of distributing fresh orders for pig iron this week. But if sales of pig iron have been small, deliveries have been very heavy; in fact, altogether there have never been more favourable statistics in connection with the pig iron trade of the North of England, and these do not justify the prices that are now ruling. The production is the largest on record, yet it is more than equalled by the present requirements, and it is estimated that the stock of Cleveland pig iron at the close of the month will show a decrease of at least 5000 tons. The great activity in trade is also attested by the pig iron exports, which are the best on record; this is the more remarkable because June is usually a quiet period for exporting. It was generally predicted in the early part of the month that deliveries oversea would slacken, especially when they had been so much above the average during the previous three months; but instead of that they have further increased, and from the Cleveland district to Wednesday night they have this month reached 87,614 tons, as compared with 78,345 tons last month, 84,517 tons in April, and 82,774 tons in June, 1895, to 24th. The deliveries to local and inland works are also large, and are likely to continue so, judging from the reports of consumers respecting their business.

The production of pig iron this month will be smaller than it was last month, and a larger proportion will be of the commoner qualities. Hitherto this year it has been somewhat difficult at times to procure No. 4 foundry and all forge qualities, more especially white, because the furnaces were working so well that their output was chiefly Nos. 1 and 3. But the hot weather this month has brought about an alteration, and quantity and quality have suffered, so that some producers have found it difficult to fulfil promptly all their orders for No. 3.

Makers generally have this week kept to their last week's quotations for Cleveland pig iron; but merchants and some of the producers, influenced by the fall in warrants, have been accepting lower rates. Thus No. 3 Cleveland pig iron for prompt f.o.b. delivery has been obtainable at 37s. 3d., and some will accept 37s. 6d. for deliveries to be made over the next two months; but few consumers will buy for forward delivery when the warrant market is so flat. No. 1 is sold at 38s. 6d. Cleveland warrants, which last week fluctuated about 37s. 6d. cash, have this week been about 37s. 1d. The return of stock of Cleveland pig iron in the public warrant stores is satisfactory; in fact, it is some years since it was so much in favour of the sellers. Connals on Wednesday night held 199,152 tons, or 702 tons increase this month. No. 4 Cleveland foundry pig iron has dropped to 36s. 6d.; grey forge to 36s.; and white to 35s. 9d., all for early delivery. Cleveland pig iron, and especially the Redcar brand, is finding increasing favour in Japan. This week a very large four-masted sailing vessel, the Prince Robert—a Liverpool-built but Norwegian-owned ship—is taking in at Messrs. Walker, Maynard, and Co.'s wharf a cargo of their Redcar pig iron for Japan.

Mixed numbers of East Coast hematite pig iron are obtainable at 45s. 6d. per ton, but makers generally hold out for more. Rubio ore continues firm at the recent advance, and scarcely any can be procured under 12s. 9d. per ton, delivered at Tees wharves, or 7s. 4½d. f.o.b. Bilbao. Consumers are apprehensive that a tax on iron ore exported will be put on by the Spanish Government, so as to help to provide funds to quell the rebellion in Cuba.

The finished iron and steel industries are generally in an encouraging condition, work is plentiful and prospects good. Some of the bar manufacturers say they have never known the demand to be so brisk, and they have this week advanced their quotations 2s. 6d. per ton. The demand is specially good for the lighter descriptions of iron and steel, such as sheets, rounds, flats, rivets, bolts, wire rods, nails, &c., and the production of these has not for many years been so large as it is at present. Common iron bars are now £5 per ton, less 2½ per cent. f.o.t. Steel ship plates are at £5; steel boiler plates, £6; steel girder plates, £5 5s.; steel ship angles, £4 17s. 6d.; steel engineering angles, £5; iron ship plates, £4 17s. 6d.; iron angles, £4 15s.; all less 2½ per cent. f.o.t. Heavy steel rails are nominally at £4 10s. net at works, but producers have to be content with considerably less where the competition is keen. Cast iron chairs are in brisker request than has been known for some years, as there is now very little competition with steel sleepers, and something better in the way of prices should be realised; at present, £2 17s. 6d. net at works has to be taken.

The directors of Messrs. Head, Wrightson and Co., Teesdale Iron and Engineering Works, Thornaby-on-Tees, report that during the year ended April 30th last their gross profit was £15,467 11s. 1d.; to this they add £249 8s. 6d., and they propose to distribute the total as under:—£5122 1s. 7d. in interest on debentures, £5250 in a 2½ per cent. dividend for the year to the ordinary shareholders, £5166 13s. 4d. in direction and management fees, and a balance of £178 4s. 8d. is to be carried forward to next year. The contracts on hand are stated to be considerable and though prices are low, it is anticipated that a fair profit will be realised. In order to execute contracts within the stipulated time for delivery, the directors have, as already reported in these columns, rented the Eaglescliffe Foundry, near Stockton—a foundry which was established and worked by Messrs. H. Smith and F. W. Stoker, but has been idle for some years.

On Saturday last Messrs. Furness, Withy, and Co. opened a new graving dock at their shipyard at Middleton, near Hartlepool. The dock has been rendered necessary on account of the great extension of their business and the rapid growth of their fleet. It possesses every facility for the quick docking and undocking of vessels of the larger type, and being a tidal dock, it can be entered direct from the harbour without the vessel having to pass through locks of any kind. A large engine repairing shop, about 400ft. in length, has been built on the west side of the dock, together with copper and brass finishing shops. A "Goliath" crane, nearly 80ft. high, and capable of lifting up to 80 tons, has been erected. In connection with this yard a large new frame turning furnace and plant has been erected—one of the largest in the country—and with this and other new appliances Messrs. Furness, Withy, and Co. will be able to build similar steamers to the latest Cunarders. They have now some very large steamers in course of construction—one of about 6000 tons, for Messrs. Thomas Wilson, Sons, and Co., Hull. Within the last eighteen months the firm have reconstructed the whole of their works, and that without stopping in the least the building of vessels, for their last year's record was the largest in the company's records. The firm have put down a powerful electric installation to drive the whole of their machinery, and it is claimed that the Middleton shipyard is the only one in the country where the whole of the motive power is generated by electricity, and distributed from a central station over the entire works.

The death is recorded of Major Matthew Gray, the eldest son of Sir William Gray, the eminent shipbuilder, and also head of the Central Marine Engineering Works at West Hartlepool. Mr. M. Gray was connected with the shipyard, and was also proprietor of the West Hartlepool Iron and Steel Works; he was forty-one years old. Mr. John Atkinson, who has for many years been connected with the Seaton-Delaval Coal Company, died on the 19th inst.

The coal trade is dull, and is more so than usual this week, because in the Newcastle district the most of the collieries are idle owing to the races. Prices, however, are maintained, best Northumberland steam being at 8s. 6d. per ton f.o.b., and smalls 3s. 9d., whilst best Durham gas coals are 6s. 3d. to 6s. 6d. f.o.b. Coke can be bought at 13s. 6d. per ton delivered at Middlesbrough furnaces, and sellers are not so firm in their prices, owing to the plentiful supply.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market was fairly active early in the week. On Monday about 60,000 tons of Scotch warrants were reported to have changed hands at from 46s. 1d. to 46s. 4d. cash. It was understood that considerable purchases were being made to cover over sales, but when these were completed, the prices reacted somewhat, and business was done in Scotch warrants down to 45s. 11½d. cash. There was comparatively little doing in Cleveland warrants, which sold between 37s. 1½d. and 37s. 0½d. cash. Hematite warrants were quiet from 46s. 11½d. to 47s., and down to 46s. 10½d. cash.

There is little or no change in the amount of the pig iron output. Ordinary pig iron is being made by thirty-eight furnaces, hematite by thirty-nine, and basic by three; the total of eighty furnaces now in operation in Scotland, comparing with seventy-five at this time last year.

Stocks of pig iron are accumulating, the addition in the Glasgow warrant stores in the past week amounting to 1194 tons, bringing up the total stock to 363,200 tons, compared with 282,220 tons at this time last year. The present cost of making pig iron is so moderate that merchants have little hesitation in purchasing for the store, and makers also appear to be of opinion that storing may ultimately be found to pay.

There is a fair demand for the different qualities of Scotch makers' pig iron. Prices, which had been nominally steady for a number of weeks, have, at length, given way a little, but in the circumstances of the trade the figures are still considered fairly satisfactory. Govan, and Monkland, f.o.b. at Glasgow, No. 1, are quoted 47s. 3d. per ton; No. 3, 45s. 9d.; Carnbroe, No. 1, 47s. 6d.; No. 3., 46s.; Clyde, No. 1, 49s. 6d.; No. 3, 46s. 6d.; Gartsherrie, Calder, and Summerlee, Nos. 1, 50s.; Nos. 3, 47s. 9d.; Coltness, No. 1, 52s. 6d.; No. 3, 48s.; Glengarnock, at Ardrossan, No. 1, 49s. 6d.; No. 3, 45s. 6d.; Eglinton, No. 1, 47s.; No. 3, 45s.; Dalmellington, at Ayr, No. 1, 46s. 6d.; No. 3, 44s. 6d.; Shotts, at Leith, No. 1, 52s.; No. 3, 48s. 6d.

Scotch made hematite pig is in steady demand, and merchants quote it at 50s. per ton free on trucks at the steel works.

The current imports of Cleveland pig iron into Scotland are not quite so good as of late, but there can be no question that the quantity of this iron going into consumption is large. The imports of the past week were 7551 tons, being 707 tons less than in the same week of 1895. Since the beginning of the year the total imports on the East Coast have been 208,460 tons, showing an increase for the year to date of 33,670 tons.

The demand for Scotch pig iron for shipment abroad is backward. The total shipments for the week, coastwise and foreign, reached 5565 tons, against 4359 in the same week of last year. Of the total the United States took 120 tons, Canada 262, South America 200, India 165, Australia 210, France 30, Italy 690, Germany 330, Holland 88, Belgium 25, Spain and Portugal 60, China and Japan 225, other countries 46, the coastwise shipments being 3114, against 2222 in the same week of last year.

The finished iron and steel branches are active, and makers and merchants report a good steady market for these materials, without appreciable change in prices.

Some very good shipbuilding and marine engineering contracts are at present in the market. Locomotive engineers, who were already very busy, working both day and night, have booked a number of fresh orders. Messrs. Dubs and Co., of Glasgow Locomotive Works, have contracted to build forty engines for the Cape, twenty for Natal, and twenty for India, and important locomotive contracts for the River Plate have gone to Newcastle.

There is not much alteration to note in the position of the coal trade. Shipments were good in the past week, reaching 164,637 tons, compared with 145,513 in the same week of 1895. Coals for manufacturing purposes at home are meeting with quite a brisk demand, but prices are still unsatisfactory. Main coal is quoted f.o.b. at Glasgow, 5s. 9d.; splint, 6s. 3d. to 6s. 6d.; ell, 6s. 3d. to 6s. 9d.; and steam, 7s. 6d. per ton.

The Corporation of Glasgow has purchased upwards of 400,000 tons of coals for the gasworks. These include 20,000 tons of first-class and 90,000 tons second-class cannel, and 70,000 tons steam coal. Splint coal was purchased at 6s. 3d. per ton. There is a reduction from last year's rates of 3d. to 6d. in the case of cannels and 1d. to 3d. in splints. The shipments have been good in Ayrshire, but coals are accumulating at the collieries there, and prices are kept down to the lowest point.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

LAST week was a good steam-coal week, and was characterised by large and steady outputs in various quarters, and a local shipment at the Cardiff ports alone of over 300,000 tons. Since then things have quieted down a little, and this week more interest is being taken in the visit of the Prince of Wales on Saturday than in ordinary business at docks and offices. Preparations are being carried out on a great scale to do honour to the event, and show the huge proportions to which Cardiff has arisen. After the furore, and when trade has got back into its old channels, I shall fully expect a good deal of activity, especially as regards best steam, the indication of this being in the large business booked for future delivery, and the firmness with which quotations are given for prompt shipment. Last week there was a fairly good coal trade at Newport. Swansea also indicated a good deal of activity, shipments to Italy being exceptionally good.

Mid-week coal quotations at Cardiff were as follows:—Best steam coal, 10s. 3d. to 10s. 6d.; special seconds, 9s. 9d. to 10s.; seconds, 9s. 3d. to 9s. 6d.; drys, 8s. 9d. to 9s.; best Monmouthshire, 8s. 3d. to 8s. 6d.; seconds, 8s.; best small, 4s. 9d. to 5s.; seconds, 4s. 3d. to 4s. 6d.; drys from 3s. 9d. House coal prices keep up fairly well. Cardiff figures are:—Best, 9s. 6d. to 10s. 3d.; No. 3 Rhondda, 9s. 6d. to 9s. 3d.; brush, 7s. 9d. to 8s.; small, 6s. to 6s. 3d; No. 2 Rhondda, 7s. to 7s. 3d. No. 2 Rhondda, 7s. to 7s. 3d.; through, 6s. to 6s. 3d.; small, 4s. to 4s. 3d. Swansea prices are:—Anthracite, best, 11s. to 11s. 3d.; second quality, 9s. to 10s.; ordinary large, 8s. to 8s. 9d.; small rubbly culm, 4s. to 4s. 6d.; steam coals, large, 9s. to 10s.; seconds, 8s. 3d. to 9s.; bituminous coals, No. 3, 9s. to 10s.; through, 8s. to 8s. 9d.; small, 6s. 3d. to 6s. 6d.; No. 2, 8s. 6d. to 9s. 6d.; through, 6s. 6d. to 6s. 9d.; small, 5s. to 5s. 3d.; patent fuel, 9s. 9d. to 10s. 3d. Cardiff prices are 10s. 3d. to 10s. 6d. Trade is fairly good at both places. Last week Swansea shipped over 8000 tons. Pitwood, Cardiff, 15s. 9d.; trade dull. Coke prices are firmly maintained. Cardiff quotations are:—Furnace, 12s. 9d. to 14s. 6d.; foundry, 15s. 6d. to 16s. 6d.; special foundry, 19s. 6d.

Iron ore market is active, and prices advancing. Cardiff prices: Best Rubio, 12s. to 12s. 3d.; Tafna, 11s. 6d. to 11s. 9d.; Garucha, 11s., c.i.f. Large quantities were received this week by the principal ironmasters. 3180 tons came into Swansea last week.

It is expected that Kenfig Hill Ironworks will start operations on July 1st. Preparations for lighting the furnaces are beginning. This is another indication of an improving iron and steel trade. In various districts the hope is expressed that the improvement will continue to spread, that there may be more activity at Tredegar, and a restart at Treforest, where everything is kept in capital order. Blaenavon and Ebbw Vale works continue busy, and at Cyfarthfa and Dowlais a better bar trade is being done, though amongst the mechanics at the latter works there is still a degree of friction which has resulted in the removal of a number of hands.

The Swansea Exchange report this week concerning the iron trade was very satisfactory. It was to the effect that the outlook in the finished iron and steel trades was better, that the principal works throughout the district were fully employed, and that the prospects of continued prosperity were assured. One good proof of this, I may add, is that the demand for Bessemer and Siemens bars are greater than the make, and in consequence prices have gone up 2s. 6d. per ton. Iron ore, too, is advanced, and quotations are 3d. per ton better. The annual report of the Ebbw Vale Company, given this week, is interesting, as giving an outlook from a thoroughly practical source.

In the matter of steel rails reference is made to the fact, tolerably well known to most business men, that quotations are not very rigidly kept, and are modified by circumstances and conditions. Heavy steel rails were sold in the first half of the year, states the report, from £3 7s. 6d., free on board, and it was impossible to conceive that any profit could be made. In the second half things took a turn for the better. This improvement was shown to a modified extent in the tin bar trade, which was an important factor at Ebbw Vale. The report admits that up to 1892 the company was unable to compete in the manufacture of tin bars, but a vigorous effort was made in cultivating the trade, and a new tin bar mill had been added. Dealing in retrospect, the report admitted that the close of the year indicated a very serious state of things. Many of the tin-plate manufacturers had been obliged to close down, and the Ebbw Vale Company found themselves at the end of the year with several thousand tons of orders on their books, for which they were unable to obtain specifications and give delivery. Within the last few days, however, there had been a marked improvement in the price of tin-bars, which encouraged the directors to hope for better things in the future. Touching upon coal, it had been stated that the selling price was 9s. per ton, but at Newport the figure for some time had been 8s., which meant 6s. at the pits, and yet the Ebbw Vale Company had been able to do better than some of their neighbours in the Rhondda and Aberdare Valley. In concluding, the report cites the Ebbw Vale Company as a sound, solid, and substantial concern, which it was not in 1892, and augured great things from the election of Sir Wm. Barley to the board. The appointment of Sir William having been confirmed, he stated in reply that he had been over the works at Ebbw Vale, and found thatmuch of the plant was out of date, and some of their processes were antiquated, but he was not without hope that the company would pay a good dividend before long.

The works at Dowlais are beginning to suffer from the drought, and unless there is a downfall greater part will be idle. This is annoying at a time when there is a good demand for bars.

Swansea quotations, iron and steel, this week indicate a reduction during the week of 9d. in Scotch pig, 6d. per ton in Cleveland, and 7d. in hematite. This shows that make exceeds demand.

On 'Change, Swansea, this week it was mentioned that there is a considerable strain on the capacity of the Bessemer works, and with the heavy rail orders which are being pressed for shipment, the deliveries of tin bars are delayed. Want of water too is beginning to tell. Quotations this week are:—Glasgow pig, 46s.; Middlesbrough 37s.; hematite, 45s.; Welsh bars, £5 10s. to £5 12s. 6d. Iron plates from £6 to £6 17s. 6d.; steel plates the same. Steel rails, heavy sections, £4 7s. 6d. to £4 10s.; light, £5 10s. to £5 12s. 6d. Bessemer steel, tin-plate bars, £4. Siemens best, £4 2s. 6d. Tin-plates, Bessemer steel cokes, 9s. 3d. to 9s. 6d.; Siemens, 9s. 6d. to 10s.; ternes, 16s. 6d., 17s., 18s. 6d., to 21s.; best charcoal, 13s. to 13s. 9d., according to finish.

Block tin is at £60 15s. to £60 17s. 6d. Copper, Chili bars, £49 10s. to £49 12s. 6d.

The tin-plate trade now justifies the belief expressed some weeks ago in this column, that the "corner was being turned," and if no rush takes place to start idle mills, I shall fully expect a steady improvement. Prices now are beginning to move up, signs of a gratifying improvement are becoming more general, and the very gradual way in which this has been brought about points to a continuance. Sudden and spasmodic movements, though exciting at the time, are generally short-lived. Large orders for black plates are being booked at several of the works at Llanelly, Morriston, and Portardulais, principally for the Continent.

At Briton Ferry a large meeting of tin-plate workers was held last week, and a resolution come to that no further reduction in wages should be conceded.

The shipments of tin-plates last week were 43,570 boxes; received from works, 50,702 boxes; present stock, 148,313 boxes.

The Cardiff tramway scheme has again been under discussion, but the matter is not yet brought to a point. Like the threefold scheme at Swansea it hangs fire.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

IRON producers report an active condition of things all round. Orders on home and on foreign account are plentiful, and quotations have been well maintained.

The Silesian iron business remains in entirely the same position as before, and there is consequently nothing of interest to be reported this week. Makers and manufacturers are all very busy, and will continue so for a considerable time. Prices are moving upwards; especially bars and girders show a rising tendency. From July 1st basis price for bars will be M. 140 p.t. at works. Output of pig iron in Silesia was, for May of present year, 53,783 t., of which 31,175 t. were forge pig, 3505 t. Bessemer, 13,448 t. basic, and 5655 t. foundry pig. Production in May, 1895, was 44,651 t. From January 1st to May 31st of the present year 250,488 t. were produced, against 213,515 t. for the same period the year before. Consumption of pig iron was, for May, 1896, 51,398 t., of which 815 t. foundry pig were exported. During the first five months of present year 254,965 t. were consumed; export amounted to 3437 t., of which Austria received 3002 t., Russia 405 t., and Roumania 30 t.

A comparatively quiet sort of trade is being transacted on the Austro-Hungarian iron market. The pig iron business is fairly active, and so is the malleable iron department, orders for bars and structural iron coming to hand pretty freely. In wire, wire nails, and axles only a moderate demand is experienced, but fairly good prices are on the whole realised. Consumption of coal on the Austrian State Railways was for 1895:—Brown coal, 700·55 t.; pit coal, 487·618 t.; and coke, 3133 t.

On the French iron market a healthy business has been done upon the week. Pig iron is selling briskly at satisfactory prices, and finished iron and steel manufacturers have also booked a considerable amount of orders, and will be able to keep their establishments in full operation for several months ahead. There is consequently no easing of prices; on the contrary, advances have, in several instances, been ventured, and with success, too. The French Northern Railway has tried, by reducing the tariffs for coke and coal from the North to the East Departments, to limit the imports of English, Belgian, and German coal. The following figures show this attempt to have been fairly successful:—

	1895. t.		1894. t.		Difference. t.
Coal from the North and Pas de Calais district	8,651,180	..	7,976,805	..	+ 674,375
Belgian coal	1,942,145	..	2,017,785	..	− 75,640
English coal	148,520	..	194,815	..	− 46,295
German coal	123,355	..	150,055	..	− 26,700
Totals	10,865,200	..	10,339,460	..	+ 525,740

General satisfaction is expressed with regard to the situation of the Belgian iron industry, and prospects are decidedly favourable. The Belgian State Railway Administration have submitted to the Chamber of Deputies a request to grant an extra sum of 36,712,290f. for the extension of railway lines, building of railway stations, and for heavy purchases in rolling material—24 locomotives and 1744 load wagons. As the Chamber is sure to consent, the activity in the engineering industries will be a very good one for several months to come.

The Rhenish-Westphalian iron market shows much briskness, while prices are generally rising; in all departments increasing employment is reported, home and foreign orders being numerous. There had been some little trace of a decrease in the demand for iron ore last week, but this week a brisk business is again transacted, and quotations are extremely firm, spathose iron ore fetching M. 9 to 9·60 p.t.; roasted ditto, M. 12 to 13 p.t.; calcined iron ore, M. 12 to 14 p.t., net at mines. Here and there orders for the first two quarters of 1897 have already been secured at advanced rates. Minette of Luxemburg and Lorraine is also well inquired for, and quotations seem inclined to rise; at date M. 240 and 260 p.t. is paid for common sorts, while the 40 per cent. grade stands on M. 320 p.t. at mines. The pig iron market does not present any perceptible change since last week, the activity at the blast furnaces being as good as can be. Both prices and demand exhibit an inclination to rise, and stocks are very small now. For spiegeleisen, 10 to 12 per cent. grade, M. 59 p.t. is quoted; forge pig, No. 1, M. 53 to 55 p.t.; No. 3, M. 42 p.t.; hematite, M. 65 p.t.; foundry pig, No. 1, M. 65 p.t; No. 3, M. 57 p.t.; basic, M. 54 p.t. Iron for making steel, M. 53 to 54 p.t. at works. Luxemburg forge pig is offered at 56f. p.t., free Luxemburg.

In all branches of the malleable iron industry the business done is most satisfactory. Some fairly good export orders have been coming in, which, added to the continually increasing demand on home account, promise good employment for the remaining part of the year. Bars continue very briskly called for, and are exceedingly firm in quotation; the South German Rolling Mill Convention raised basic prices for bars on M. 121 p.t., free Neunkirchen. Hoops are in lively request, and so are plates, which have been fetching better prices, an allowance of M. 5 p.t. having been agreed upon last week. The sheet mills are at present rather less active than during the previous month, but this does not affect the general tone, makers being just as confident as before, and expect a lasting improvement in demand to take place in a few weeks. The majority of the machine factories and construction shops are vigorously engaged, and report their prices to be in better proportion to those of the raw materials.

This week's list quotations per ton at works are as under:—Good merchant bars, M. 120 to M. 122; angles, M 130; hoops, M. 125; billets in basic and Bessemer, M. 85 to M. 86; heavy plates, for boiler-making purposes, M. 165 to M. 170; tank plates, M. 135 to M. 140; steel plates, M. 145 to M. 150; tank ditto, M. 120 to M. 125; sheets, M. 155 to M. 160; iron wire rods, common quality, M. 130; drawn wire in iron or steel, M. 120 to M. 138; wire rails, M. 127 to M. 130; rivet iron, M. 140 to M. 142; rivets, good merchant quality, M. 185 to M. 190; complete sets of wheels and axles, M. 280 to M. 290; axles, M. 220; steel tires, M. 200; steel rails, M. 118; steel sleepers, M. 110; fish-plates, M. 120 to M. 130; light section rails, M. 100.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, June 18th.

THE commercial situation is on the eve of an improvement, which will probably bring with it stronger prices for immediate deliveries of iron and steel products and general merchandise. The industries are not crowded. Prices are weak. The strongest possible inducements held out to consumers to anticipate fall requirements fail to bring out orders for more than current requirements. Pig iron production is declining, and stocks are slowly increasing. Billets are kept at combination prices, and coke and ore at their early spring figures. Various associations and combinations unite manufacturing interests in the maintenance of quotations a notch or two above what unrestricted competition would fix. The out look is encouraging. Iron reports from a dozen interior centres indicate an unsettled condition. The Amalgamated Association desire an advance in wages, which manufacturers are not inclined to grant. Bar iron makers have not effected a working association. The nail makers see breakers ahead in an accumulation of stock. The plate and structural material manufacturers count on a busy half-year, because of the large amount of construction and bridge work determined upon. If the announcements of the railroad and engineering journals are to be taken as true, there will be a very great increase during the next twelve months in the amount of general work involving plates and shapes. Boatbuilding on the Lakes is promising. Small bridge work for street crossings and small streams is quite a feature. Girder rails on tramways are now wanted for many lines. With the promulgation of a political platform this week at St. Louis, the business interests well know what is to be policy of the next Administration, and it it probable that much delayed work will then be taken in hand.

THE INSTITUTION OF CIVIL ENGINEERS.—Mr. J. H. T. Tudsbery, M. Inst. C.E., has been appointed secretary of the Institution. Mr. James Forrest who has so many years directed its affairs having now retired to enjoy a well-merited repose.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

*** When inventions have been "comunicated" the name and address of the communicating party are printed in italics.

10th June, 1896.

12,744. Aerial Machines, F. W. Lanchester, London.
12,745. Horseshoes, S. Gillmah, London.
12,746. Two-pin Plug for Electric Lamps, W. J. Head, London.
12,747. Wheels for Tires of Bicycles, C. A. Rollason, London.
12,748. Breaking Balls of Tea Leaves, N. W. H. Sharpe, London.
12,749. Protecting Cover for Cyclists, R. Stead, London.
12,750. Hair-pin, A. C. Gibson, London.
12,751. Bottles for Preventing Fraud, E. M. Llewellyn, London.
12,752. Lamps, S. Galpin, London.
12,753. Rotary Strainers for Paper Pulp, H. Hobday, London.
12,754. Cycles, J. Brooks, Birmingham.
12,755. Electrical Insulation, The Telegraph Manufacturing Co., Ld., Helsby.
12,756. Brakes, D. H. Croll, Watford.
12,757. Driving Pulleys, T. C. Dennison, F. H. E. Shipton, and L. S. Carr, London.
12 758. Motive Power Engine, &c., H. M. L Crouan, London.
12,759. Facing Points for Permanent Way, H. Burnham, London.
12,760. Reservoir Attachment for Pens, M. A. Alves, London.
12,761. Reed Instruments, J. D. Brunton and H. Smith, London.
12,762. Attaching Labels to Bottles, F. B. Pye, London.
12,763. Air Guns, O. Will, London.
12,764. Drying Tea, W. A. Gibbs and G. W. Sutton, London.
12,765. Dissolving Drying Phosphates, J. Milne, London.
12,766 Brushes with Curved Backs, C. E. Flemming, London.
12,767. Casting Armour-plates, &c., H. V. Holden, London.
12,768. Pneumatic Tires for Cycles, J. C. Grant, London.
12,769. Felloes for Cycle Wheels, J. C. Grant, London.
12,770. Chains, M. A. Wier, London.
12,771. Producer and Water Gas, C. Whitfield, London.
12,772. Means for Producing Designs, T. Sardnal, London.
12,773. Petroleum Burners. H. Schneider, London.
12,774. Sprinklers, R. W. Newton, London.
12,775. Automatic Fire-extinguisher, R. W. Newton, London.
12,776. Rotary Explosion Motor, W. Hildebrand, London.
12,777. Attaching Air Pumps to Cycles, A. Stevens, London.
12,778. Vehicles and Boats, W. Ullrich and F. Biesecke, London.
12,779. Planting Trees and Posts, I. Panamá, London.
12 780. Pressing the Legs of Trousers, E. S. Doré, London.
12,781. Casting Stoppers, J. Hickling and T. Slater, London.
12,782. Carbonising Iron, A. Wilson and F. Stubbs, London.
12,783. Cover for Pneumatic Tires, E. S. Cook, London.
12,784. Pneumatic Tires, W. P. Thompson.—(*A. Fraipont, Belgium*.)
12,785. Reaping and Harvesting Machine, J. C. Moore, London.
12,786. Aerial Machines, H. S. Booth, Manchester.
12,787. Metallic and other Articles, T. P. Taylor, Birmingham.
12,788. Generating and Storing Acetylene, R. R. Gibbs, Liverpool.
12,789. Mouldings, J. Skegg, Manchester.
12.790. Driving Apparatus for Cycles, J. Higginbottom, Liverpool.
12,791. Cycle Tires, T. H. O'Brien and W. H. Sisson, Manchester.
12,792. Saucepan Brushes, C. Phillipsbourne, London.
12,793. Attachment for Drinking Vessels, C. C. Hull, London.
12,794. Propelling Cycles, G. S. Edwards, London.
12,795. Engines, E. J. Clubbe, A. W. Southey, and the Electric Motive Power Co., Ld., London.
12,796. Hammers, &c., M. Millar, C. Mossman, and S. Williams, London.
12,797. Velocipedes, A. Reyrol, London.
12,798. Lifts, I. Cizek and L. Maizner, London.
12,799. Stair Treads, F. Sage, London.
12,800. Driving Bands or Chains, W. G. Birkinshaw, London.
12,801. Gloves and Articles of Dress, P. E. L. Pedrizet, London.
12.802. Fasteners for Gloves, &c., P. E. L. Pendrizet, London.
12,803. Protective Advertising Covers, L. Echenard, London.
12,804. Cycle Variable Speed Gear, J. J. Truchot, London.
12,805. Oil Engines, G. J. Altham, London.
12,806. Sheave Mountings for Aerial Ropeways, J. P. Roe and The Ropeways Syndicate, Limited, London.
12,807. Nut-locks, C. C. Newton, London.
12,808. Brakes for Cycles, C. F. Rowe, London.
12,809. Gloves, E. Beck, London.

11th June, 1896.

12,810. Pneumatic Bearing for Cycles, W. S. Shreeve, Warwick.
12,811. Single Trigger Guns, F. Beesley, London.
12,812. Plaister for Dressing Wounds, T. D. Vint, Hastings.
12,813. Cog-wheels and Chain of Bicycles, &c., A. Hamilton, Belfast.
12,814. Burner for Incandescent Gas Lighting, J. Wilson, Birmingham.
12,815. Castors for Furniture, &c., H. S. Stewart, London.
12,816. Brakes for Bicycles, &c., J. R. Stoney, Dewsbury.
12,817. Steering Ships, T. A. Kennedy, Liverpool.
12,818. Machinery Granulating Oil-cake, J. Evans, Liverpool.
12,819. Chains for Cycles, E. D. Hopcroft, Kidderminster.
12,820. Motion for Working the Scrapers of Fuel Economisers, J. Pimbley, sen., and J. Pimbley, jun., Moses Gate, near Bolton.
12,821. Appliance for Attachment to Coats, R. E. Gribble, Bristol.
12,822. Rotary Engines, J. G. Whittles, S. H. Ogden, and S. Douglas, Manchester.
12,823. Protecting Pad for Backs of Picture Frames, J. Stewart, Glasgow.
12,824. Carriage Windows, E. H. Warden and G. P. Underhill, Birmingham.
15,825. Making Earthenware Jars, W. Ralston, Glasgow.
15,826. Coupling for Hose Pipes, J. Stuart, Glasgow.
12,827. Furnaces for Heating Floors, F. W. Knowles, Halifax.
12,828. Wood-sawing Machinery, G. Pickles, Halifax.
12,829. Castor Pegs for Metallic Bedsteads, &c., G. Dawes, Birmingham.
12,830. Removing Seeds from Raisins, G. Dawes, Birmingham.
12,831. Apparatus for Motor Carriages, W. G. Potter, London.
12,832. Illuminating Lamps of Cycles, L. Stokvis, London.
12,833. Clothing, Barbage, Friendship and Co., Ld., Plymouth.
12,834. Riding Saddles, A. C. Russell, Walsall.
12,835. Stretching Woven Fabrics, T. O. Arnfield, Manchester.
12,836. Method of Securing Letters, G. O. F. Hoffmann, Manchester.
12,837. Pneumatic Saddles for Cycles, W. S. Sharpe, London.
12,838. Elastic Tire, R Ashcroft and E. A. Sturgess, Birmingham.
12,839. Propelling Steam Ships, W. Evans, Swansea.
12,840. Manufacture of Artificial Fuel, H. Hellewell, Manchester.
12,841. The Moss Wirette, J. Moss, Birmingham.
12,842. Fabric Fastener, A. D. Macpherson and H. Hudson, London.
12,843. Puncture Proof Band, C. C. Hewett, London.
12,844. Water-proof Case or Shield, G. B. Smith, London.
12,845. Attaching Pneumatic Tires, J. P. Field, London.
12 846. Cigarette Case and Matchbox, G. Lieberman, London.
12,847. Cork Band Curvilinear, C. S. Urry, C. A. and L. W. Bangley, London.
12,848. Waste or Slop Water Closets, A. Hocking, London.
12,849. Driving Gear for Cycles, A. Davy and T. Wallace, Birmingham.
12,850. Raising and Dressing Turnips, T. Robson, London.
12,851. Transmitting Power, H. W. Handcock and A. H. Dykes, London.
12,852. Autocar Motors, R A. Marsh, London.
12,853. A New Letter Envelope, E. Rinzi, London.
12,854. Bicycle Tires, J. H. Loch, London.
12,855. Generating Vapour, T. Hawkins and A. Wellby, London.
12,856. Railway and Other Points, T. Glaister, London.
12,857. Road Locomotives, R. Ord, London.
12,858. Appliance for Turning Over Leaves of Music, A. Ruddock, London.
12,859. Electric Transformers, L. B. Miller, London.
12,860. A New Suspender for Stockings, F. Beckitt, London.
12,861. A New or Improved Purse, D. E. Beak, London.
12,862. A New Mudguard for Cycles, J. Bartlett, London.
12,863. Steering Bars for Cycles, C. F. Johnson and R. West, London.
12,864. Damping Postage Stamps, &c., A. Hewens, London.
12,865. Pneumatic Tires, &c., J. F. R. Wood, London.
12,866. Wheel Axles, R. Mielchen and G. Otto, London.
12,867. Valve Gear for Steam Engines, D. H. Williams, London.
12,868. Smoke Consumers, E. T. Thomas and A. Melhado, London.
12,869. Musical Top, R. B. Waters, London.
12,870. Production of a Polished Surface, P. J. Meissner, London.
12,871. Clip Attachment for Cycles, E. G. Tuteur, London.
12,872. Boots and Shoes, P. Vigano, London.
12,873. Labels, &c., K. Bainbridge, Newcastle-on-Tyne.
12,874. Incandescence Gas Burners, L. Denayrouze, London.
12,875. Centrifugal Governors, &c., J. Milner, London.
12,876. Fastening for Straps, &c., W. L. Preece, London.
12,877. Register Stoves or Grates, J. E. Russell, London.
12,878. Making Cases, R. Dalton and H. Mardon, London.
12,879. Wagons, The Bristol Wagon and Carriage Works Company, J. McDonald, and W. S. Hek, London.
12,880. Pneumatic Tires for Cycle Wheels, J. M. Boyer, London.
12,881. Score Recorder for Golfers, W. G. Forbes, London.
12,882. Velocipedes, F. G. Pickering, London.
12,883. Pneumatic Tires for Cycles, H. C. Sanders, London.
12,884. Lamp Globes, I. Reich, London.
12,885. Log for Recording Speed, F. W. Marriott, London.
12,886. Preventing Re-filling of Bottles, T. M. Dillingham, London.
12,887. Nets, J. Wilson, London.
12,888. Pneumatic Tires for Bicycles, E. A. Reeves, London.
12,889. Kilns for Burning Cement, W. S. Akerman, London.
12,890. Pens, O. Reich, London.
12,891. Can Opening Machines, R. W. Barker.—(*W. N. Anderson, United States*.)
12,892. Production of Pictures, T. R. Shillito.—(*B. Rosenbaum, Austria.*)
12,893. Velocipedes and other Vehicles, D. Cook, Surrey.
12,894. Apparatus to Form a Sieve, L. Tucker, Bucks.
12,895. Elevators, H. R. Smith, Chicago.
12,896. Bicycles, P. T. Gorst, Liverpool.
12,897. Finishing Waterproof Fabrics, M. Frankenstein, Manchester.
12,898. Lamps, A. M. Wade, Birmingham.
12,899. Appliances for Aligning Shafting, W. Alexander, Liverpool.
12,900. Manufacture of Acetylene Gas, S. Earl, London.
12,901. Propulsion of Tram-cars, &c., H. Lane, London.
12,902. Glove Material, J. Kershaw and Dent Allcroft and Co., London.
12,903. Rods, J. Bull, London.
12,904. Process for Smoking Salmon, C. Waldemann, London.
12,905. Hardening Plates, A. Wilson and F. Stubbs, London.
12,906. Taking Photographs, J. B. Medland and W. H. Wood, London.
12,907. Sieves of Machines for Flour, R. Lund, London.
12,908. Apparatus for Drying Materials, W. Crawford, London.
12,909. Bridges, &c., A. Lees and E. C. Jenkins, London.
12,910. Steam Boiling Apparatus, C. Kellner, London.
12,911. Runner Nipples for Pipes, E W. Beach, London.
12,912. Ball Bearing, P. F. Turner and E. Klahn, London.
12,913. Sash Fasteners, F. B. Townsend and H. R. Wheeler, London.
12,914. Pianoforte Actions, F. Newman and C. Parkinson, London.
12,915. Tobacco Pipes, W. H. Wheatley.—(*C. Lancon, France.*)
12,916. Dough Kneading Machine, J. Giering, London.
12,917. Tops, E. Gregory, London.
12,918. Delivering Supplies of Soap, J. C. C. Read, London.
12,919. Supports for Carrying Paper, J. C. C. Read, London.
12,920. Drawing Corks from Bottles, J. C. C. Read, London.
12.921. Attaching Tires to Wheels, C. F. A. H. Bagot, London.
12,922. Cotton Matters, A. G. Green and A. Wahl, London.
12,923. Shading Glass, B. A. Knappett and J. F. Charlesworth, London.
12,924. Gas Burners, A. J. Boult.—(*A. Wunderlich*, ———.)
12,925. Blocks for Paving Purposes, J. Russell, London.
12,926. Detachable Tires, W. Cross and W. M. Angus, London.
12,927. Stall for Bicycle Stables, E. S. Piper, London.

12th June, 1896.

12,928. Mechanism for Operating Counters, A. R. Fairer, London.
12,929. Pneumatic Tires, A. T. J. Cutmore and C. S. Furlong, London.
12.930. Covers, J. Bray, London.
12,931. Hubs, S. Cooper, Oldham.
12,932. An Adjustable Scarf, &c., J. C. Cook, Kent.
12,933. Treatment of Ores, C. Sharland.—(*L. R. Scammell, Australia.*)
12,934. Treatment of Ores, C. Sharland.—(*L. R. Scammell, Australia.*)
12,935. Treatment of Ores, C. Sharland.—(*L. R. Scammell, Australia.*)
12,936. Driving Belt for Bicycles, A. W. Murray, Dublin.
12,937. Examination Scale Indicator, G. Truslove, Birmingham.
12,938. Manhole Frames and Covers, F. C. Lynde, Manchester.
12,939. Pressure Intensifiers, O. Robinson, J. Whitelegg, R. F. C. Tonge, and J. Butterworth, Manchester.
12,940. Toys, J. Walker and W. Keach, Birmingham.
12,941. Wheel Tires for Cycles, S. Hancock, Nottingham.
12,942. Treating Acetylene, T. Thorp and T. G. Marsh, Manchester.
12,943. Gas Generating Apparatus, W. Rowbotham, Birmingham.
12,944. Tubular Kitchen Range Boilers, C. Boddy, Manchester.
12,945. Cocks, A. E. Mathewson, Sheffield.
12,946. Cycle Frame, H. Cooper, Bristol.
12,947. Manufacture of Hosiery, &c., S. Smith, Leicester.
12,948. Cycles, R. R. Newlove and H. W. Hill, Nottingham.
12,949. Buckles, J. Bidgood, Gateshead.
12,950. Ball Bearings for Tires, J. Wadham, Dewsbury.
12,951. Oilless Wick Safety Burner, R. P. Beattie, London.
12.952. Scissors Sharpener, H. Mellars and J. D. Owen. Abergavenny.
12,953. Soap or Cleansing Agent, H. W. Wilson, Manchester.
12,954. Spoke Cleaner, C. G. Mancha-Bennett, London.
12,955. Vehicle Wheels, F. S. D. Scott. London.
12,956. Anti-pneumatic Tire, A. Young, Edinburgh.
12,957. Pneumatic Tires for Cycles, J. W. Boyce, Cheltenham.
12,958. Elasticity of Compressed Rubber, S. S. Hazeland, Penzance.
12,959. Arc Lamps, F. W. Branson, Leeds.
12,960. Rag Pulling Machines, L. Glover and C. Wilby, Leeds.
12,961. Cleaning Bearings in Machines, B. Ryan, Brighton.
12,962. Stalk Fibres, K. T. Sutherland and G. Esdaile, Chorlton-upon-Medlock.
12,963. Construction of Cycles, &c., J. Murrie, Glasgow.
12,964. Rat Traps, W. Thompson and F. Buckland, Surrey.
12,965. Taking the Bridles of Trawl Nets, J. Norfolk, London.
12,966. Tiles, &c., E. Charlesworth and E. Parkin, London.
12,967. Cigars, Cigarettes, &c., C. and J. W. Hughes, Birmingham.
12,968. Safety Lamp Burner, W. S. Buckmaster, London.
12,969. Hay Tedders, J. and R. Stenner, London.
12,970. Fitting Handles to Tea-pots, H. J. T. Greaves, London.
12,971. Kettles, Saucepans, &c., H. J. T. Greaves, London.
12,972. Wheel Nave, G. Marie, London.
12,973. Spring Saddles for Cycles, E. P. Allam, London.
12,974. Pneumatic Tires, B. L. Mosely, Hastings.
12,975. Strengthening Pneumatic Tires, M. R. Ward, London.
12,976. Saddle for Cycles, R. P. Heilgers and P. C. Smith, London.
12,977. Apparatus for Tracing Drawings, E. T. Ward, London.
12,978. Nasal Respirators, D. Holloway, London.
12,979. Welding Furnaces, E. Blass, London.
12,980. Knitting Machines, &c., W. Start, Nottingham.
12,981. Prevention of Horses Running Away, R. Beel, London.
12,982. Scoring in Billiards, &c., W. Smetham, London.
12,983. Plate for Secondary Batteries, R. N. Lucas, Woking, Surrey.
12,984. Spanners or Wrenches, W. H. Tildesley, Birmingham.
12,985. Pneumatic Tires for Cycles, S. Bunting, Birmingham.
12,986. Tires, E. B. Ricketts and R. M. Cunningham, London.
12,987. Motor Cars, E. B. Ricketts and R. M. Cunningham, London.
12,988. Paper Cuff Protectors, &c., F. C. Watts, London.
12,989. Oil Lamps, F. J. Duggan and C. Isaac, London.
12,990. Device for use in Bottle Stoppers, F. J. Reinisch, London.
12,991. Fire Bricks, G. Kynoch and Co., E. Jones, and W. East, London.
12,992. Brakes for Cycles, W. Gilbert, London.
12,993. Attaching Door Handles to Spindles, N. Dawson, London.
12,994. Pneumatic Tires, J. Collbran, London.
12,995. Cycles, E. H. O. R. Ropner, Jun., London.
12,996. Vending Machines, E. Shaw, London.
12,997. Cycles, W. F. Williams, London.
12,998. Shirts, J. E. Jack, London.
12,999. Reservoir Attachment for Pens, M. A. Alves, London.
13,000. Process of Printing, R. A. Bolam, London.
13,001. Combined Back Rest for Cycles, J. Casey, London.
13,002. Stopping Run-away Horses, A. Howell, London.
13,003. Pneumatic Tires, J. C. Grant, London.
13,004. Discharge Valve, E. B. Caird and T. J. Rayner, London.
13,005. Multitubular Boilers, J. Brunlees and J. Walker, London.
13,006. Collecting Dust, W. P. Thompson.—(*Hofer and Küntzel, Switzerland.*)
13,007. Brakes for Cycles, F. J. Longton, Liverpool.
13,008. Covering for Steam Pipes, E. Jones, Manchester.
13,009. Apparatus for Sowing Maize, K. Puskas, Liverpool.
13,010. Manufacture of Anchors, E. Shore, Liverpool.
13,011. Cycles, H. C. Smith, London.
13,012. Incandescent Gas Lamps, R. Atchison, London.
13,013. Cycle Brakes, R T. Ford, London.
13,014. Diving Apparatus, J. and G. Day, London.
13,015. Stockings, H Ford, London.
13,016. Saddles for Cycles, W. H. M. Grimshaw, London.
13,017. Lock Furniture, A. Porter, London.
13,018. Tires for Vehicle Wheels, C. H. L. Poppe, London.
13,019. Changing Photographic Plates, J. W. Jeyes and A. L. Adams, London.
13,020. Washing and Drying Butter, T. Bradford, London.
13,021. Material for Surgical Bandages, E. Hirsch, London.
13,022. Screw Nail, J. B. Cummins, London.
13,023. Casings for Electric Conductors, H. Reason, London.
13,024. Tires of Cycles, J. J. Kempster, London.
13,025. Supporting the Backs of Cyclists, E. G. Fellows, London.
13,026. Separating Butter Milk, J. B. Alliott and A. S. Barham, London.
13,027. Toys or Games, H. Eschweger.—(*F. von Holzhausen, Germany.*)
13,028. Filler to Charge Reservoir Pens, W. T. Shaw, London.
13,029. Mucilage Bottles, W. P. Turner, London.
13,030. Toy and Game Devices, W. W. Flye, London.
13,031. Sharpening Scissors, &c., N. J. St. Hilairé, London.
13,032. Extinguishing Fires, R. A. Lewis, London.
13,033. Locks for Bicycles, C. Fussmann, Germany.

13th June, 1896.

13,034. Extracting Gold from Ores, J. B. Torres, London.
13,035. Velocipedes, W. Starley, Coventry.
13,036. Trouser Clip, W. D. Sheppard and A. J. Knowlman, Exeter.
13,037. Ball Bearings for Bicycles, G. J. Beedham, Sheffield.
13,038. Wood Working Machinery, J. Bradbury, Manchester.
13,039. Vehicle Lamps, C. Dunn and A. V. Taylor, Birmingham.
13,040. Adjustable Vignetter, A. Salmon, London.
13,041. Hose Connections for Water Taps, J. H. Clarke.—(*J. Jay. Australia.*)
13,042. Knitting Machine Mechanism, A. G. Brookes.—(*G. D. Mayo, United States.*)
13,043. Steam Engines, T. P. Rennoldson, Southampton.
13,044. Puncture Proof Pneumatic Tires, E. Oades, Berks.
13,045. Bacon Slicing Machine, H. Bennett, Darlington.
13,046. Cleats for Electric Wires, F. B. Evans, London.
13,047. Measuring Silks, Cloths, &c., R. E. James, Swansea.
13,048. Electric Lamp and Oil Can, J. Rhodes and J. Henderson, Wakefield.
13,049. Eye Fastener for Curtains, K. E. Neville, Dublin.
13,050. Pneumatic Boot Appliances, S. W. Fildes and C. Harrap, Manchester.
13,051. Lamp for Railway Drays, J. J. Smith, Wolverhampton.
13,052. Paper for Catching Flies, J. W. Dougal, Glasgow.
13,053. Handle Bars of Cycles, T. Shore, jun., Manchester.
13,054 Lock-up Liquor Frames, W. D. Lloyd, Birmingham.
13,055. Pneumatic Tires, A. Latimer, R. W. Edlin, and G. W. Hands, Birmingham.
13,056. Improved Rotary Motor, J. McCarthy, London.
13,057. Cycle Driving Gear, W. H. Baraclough, Birmingham.
13,058. Wallets or Pouches, A. Timpe and P. W. Deacon, Manchester.
13,059. Fast Warp-pile Fabrics, O. Drey, Manchester.
13,060. Burners for Incandescent Gas Lamps, A. MacDonald and A. Paterson, Glasgow.
13,061. Washing, &c., Potatoes, J. Robinson, Manchester.
13,062. Tires of Wheels for Cycles, M. A. Walton, London.
13,063. Cleaning Varnish Brushes, A. R. Pollard, Worthing.
13,064. Cycle Stands, M. Aspinall, Wigan.
13,065. Matches, A. A. Brown, Glasgow.
13,066. Mop, J. Mason and Sons and R. Stafford, London.
13,067. Securing Strings to Boxes, A. Truelove, Sheffield.
13,068. Nail Cutting Machines, J. Boothman, Manchester.
13,069. Miners' Lamps, T. Mawson and J. Peel, London.
13,070. Scissors with India-rubber Handles, A. J. Seabourne and A. M. Lee, London.
13,071. A New Toy, R. C. Leathem.—(*A. G. Murray, United States.*)
13,072. Files for Papers, P. W. Peckham, Glasgow.
13,073. Apparatus for Working Punkahs, F. Shirtliff, London.
13,074. Electrical Resistances, A. J. Marquand and D. Lowden, London.
13,075. Raising Window Blinds, W. Ford and G. Paterson, London.
13,076. Driving Gear for Cycles, J. E. Preston, London.
13,077. Manufacture of Bricks, &c., H. Wood, London.
13,078. Screw-cutting Machine, W. P. Thompson.—(*G. Siewerdt and Co., Switzerland.*)
13,079. Dry Batteries, W. P. Thompson.—(*C. C. Lesenberg, Germany.*)
13,080. Electric Meters, A. Lotz, Manchester.
13,081. Cycle Handle-bar Adjustment, H. Smith, London.
13,082. Bottle Stoppers, M. Smith and J. E. Freeman, Liverpool.
13,083. Collapsible Boxes and Lids, H. Taylor, Manchester.
13,084. Bicycles, A. Denton, Liverpool.
13,085. Velocipedes, W. D. Adnitt, London.
13,086. Forcing Hair, J. Wallace and J. Huddleston, London.
13,087. Handles for Velocipedes, J. H. and L. F. Papps, London.
13,088. Carts, S. Robson, London.
13,089. Gear Chains, L. Milne, London.
13,090. A New or Improved Cuff Link, H. Brazil, London.
13,091. Testing Postage Stamps, L. U. Gill and C. F. D. Hall, London.
13,092. Cycle Saddle, H. W. Dover and P. Phipps, London.
13,093. Improved Manufacture of Dyes, H. R. Vidal, London.
13,094. Machines for Haymaking, A. C. Bamlett, London.
13,095. Frictional Gearing, B. Blackburn, London.
13,096. Treating Waste Substances, T. H. Cobley, London.
13,097. Treadle Driving Gear, O. G. Bolitho, London.
13,098. Producing Animated Photographs, P. Gautier, London.
13,099. Surgical Mattresses, A. M. Heath, London.
13,100. Railway Signals, W. H. J. Lance, Middlesex.
13,101. Motor or Horseless Carriages, E. Roger, London.
13,102. Elastic Tire for Wheels, A. C. Brown, London.
13,103. Manufacture of Tea Chests, J. C. Roberts London.

13,104. Manufacturing Cranks, A. J. Thurman, Birmingham.
13,105. Slate Pencil Sharpener, C. A. Vignoles, London.
13,106. Metal Tubes, W. S. Simpson, London.
13,107. Wheel Tires, F. A. McRae, London.
13,108. Ordnance, D. B. Morison, London.
13,109. Manufacture of Wire, D. B. Morison, London.
13,110. Pie Dishes, F. H. Fogden, London.
13,111. Manufacture of Chromium, E. A. G. Street, London.
13,112. Bolting Machines, H. Seck, London.
13,113. Sprocket Wheels, A. T. Mason, London.
13,114. Dust Cap for Cycle Bearings, J. C. Wilson, Coventry.
13,115. Acetylene Generators, C. P. Choquette and A. M. Morin, London.
13,116. Polishing Devices, H. H. Lake.—(*G. H. P. Flagg, United States.*)
13,117. Velocipedes, E. Davies and H. M. H. Goodfellow, London.

15th June, 1896.

13,118. Producing Dye-stuffs, A. Bang.—(*G. A. Dahl, Germany.*)
13,119. Shuttle Tongues used in Hand or Power Looms, W. N. Brown, W. Caithness, jun., and T. Watson, Belfast.
13,120. Cycles, F. Wynne, London.
13,121. Lamps for Cycles, J. G. A. Kitchen, Manchester.
13,122. Treating Umbilical Hernia, F. W. A. Stott, Manchester.
13,123. Water Gauge Fittings for High-pressure Boilers, H. B. and J. S. Watson, Newcastle-on-Tyne.
13,124. Cycle Lamps, R. Whitehouse and D. H. Gill, Birmingham.
13,125. Supporting Cycle Saddle Frames, G. Salter, Birmingham.
13,126. Box for Aerated Water Bottles, W. Longden, Manchester.
13,127. Weighing Machines, T. Crossley, Blackburn.
13,128. Candle Holder, C. Maggs, Swansea.
13,129. Cycle Speed Indicating Apparatus, J. B. King, Stonehouse, Devon.
13,130. Cycle Driving Mechanism, W. D. Scott-Moncrieff, London.
13,131. Cyclists' Mechanical Pacemaker, S. F. Smith, London.
13,132. Cleansing and Reducing Yeast, S. H. Wright, Monmouth.
13,133. Syphonic and other Traps, G. Chisholm, jun., Glasgow.
13,134. Cleansing Receptacles having Bulbous Parts, E. Sergent, E. E. Lambert, and R. L. Hay, Newcastle-on-Tyne.
13,135. Folding Heads of Wagonettes, J. G. Harrison, Birmingham.
13,136. Cycle and Vehicle Lamps, W. E. Simpson, Birmingham.
13,137. Making Cycle Tubes, W. Ames and W. Stokes, Birmingham.
13,138. Chimney Cowl, T. A. Dove and T. Jamieson, Glasgow.
13,139. Graduated Measured Paper for Inter-rolling Ribbons or Laces on Rolls, E. L. Enoch, Swansea.
13,140. Cycle and Motor-car Wheels, B. J. Perryman, Birmingham.
13,141. Cooling Liquids, F. Stretch, E. J. Kennedy, and J. Watson, Manchester.
13,142. Winding and Doubling Frames, F. A. Holt, Manchester.
13,143. Basket Cover, P. E. Robilliard, La Piette, Guernsey.
13,144. Producing Motive Power, R. W. Pike, London.
13,145. Construction of Ammeters, T. J. Baker, Birmingham.
13,146. Device for Retaining Hats in Shape, J. W. Dawson, Bradford.
13,147. Making Acetylene Gas, J. E. Atkinson and J. M. Labouchere, Liverpool.
13,148. Preventing Tires Puncturing, G. C. Vernon-Inkpen and J. Hewett, Southsea.
13,149. Retaining Ladies' Dress in Position, F. W. and W. N. Harland, London.
13,150. Securing Toe-pieces to Shoes, B. Watkins, Birmingham.
13,151. Duplicating Phonographic Records, H. Rheinlander, London.
13,152. Explosives, M. I. E. Morris, London.
13,153. Cycle and Motor Carriages, W. J. Giblin, Glasgow.
13,154. Quadruple Centre Punch, W. Cuttell, Derby.
13,155. Hand Power Brickmaking Machine, J. Dormer, Alton.
13,156. Puncture Tire, D. A. Rischgitz, London.
13,157. Pneumatic Tires for Cycles, J. W. Smallman, Nuneaton.
13,158. Rotary Motor for Carriages, J. Maxfield, London.
13,159. Protecting Pneumatic Tires, E. Wells, London.
13,160. Camera Shutters, J. W. Jeyes and A. L. Adams, London.
13,161. Handle Attachment for Cycles, J. Davis, London.
13,162. Price and Weight Indicator, F. Williams, London.
13,163. Underlaying Enamel, C. C. Schirm and A. Silbermann, London.
13,164. Candle Clip for Candlesticks, D. Evans, London.
13,165. Window Sashes and Frames, &c., G. Ridout, London.
13,166. Hearth Rugs, C. S. Lestir, London.
13,167. Device for Brooms and Brushes, J. T. Halsey, London.
13,168. Portable Cycle Stand, F. L. Lee, London.
13,169. Treatment of Sulphide Ores, B. Mohr, London.
13,170. Pneumatic Tires for Vehicles, T. Ballinger, London.
13,171. Advertising on Wheels, Swan and Edgar, Ld., and W. Morford, London.
13,172. Brakes for Cycles and Vehicles, R. Lanham, London.
13,173. Locks and Latches, W. Perry, London.
13,174. Medicinal Confectionery, &c., O. Marcsch, London.
13,175. Steam Traps, W. Geipel, London.
13,176. Reflecting Telemeter for Vessels, A. Belleni, London.
13,177. Driving Mechanism for Cycles, R. B. Waters, London.
13,178. Cycles or Velocipedes, C. R. Binney, London.
13,179. Lubricating Cylinders, E. J. Clubbe, A. W. Southey, and the Electric Motive Power Company, Ld., London.
13,180. Vans for Conveying Fire-escapes, E. H Bayley, London.
13,181. Facilitating Use of Glass Paper, R. Milsom, London.
13,182. Supporting Drills, J. McCulloch and J. Shaw, London.
13,183. Disinfecting Chambers, A. B. Reck, London.
13,184. Pneumatic Tires for Cycles, W. E. Kieffer, London.
13,185. Tube and Pipe Cleaner, A. Jackson, London.
13,186. Refrigerating Apparatus, &c., W. Oliver London.
13,187. Weather-proof Gypsum Stone, P. Kleber, London.
13,188. Chain Gearing for Cycles, F. Purbrick, London.
13,189. Wheels, J. Evinof, London.
13,190. Cooking Utensils, A. G. Berchtold, London.
13,191. Tires, C. H. Gray, London.
13,192. Tires, C. H. Gray, London.
13,193. Violin Bows, P. C. Nelson, London.
13,194. Securing Tubes to Mains, &c., F. Albrecht, London.
13,195. Switches for Electric Lamps, W. J. Davy, London.
13,196. White Felt Hat Bodies, E. W. Hart, Luton.
13,197. Centrifugal Machines, W. P. Thompson.—(*H. Lanz, Germany.*)
13,198. Producing Gloss on Fabrics, E. Heberlein, London.
13,199. Window Frames and Sash Pulleys, E. Cox, Manchester.
13,200. Charging Accumulators, A. G. Strömberg, Liverpool.
13,201. Tires for Road Vehicles, F. W. R. Scott, Liverpool.
13,202. Driving Gear for Cycles, T. E. Nightingale, Liverpool.

16th June, 1896.

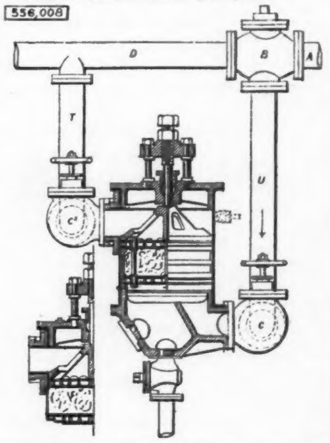
13,203. Pneumatic Tires, W. Meadows and J. Cooper, London.
13,204. Fittings for Incandescent Gas Lamps, F. S. Cripps, Surrey.
13,205. Scissors or Shears Sharpeners, J. Stewart, Fareham.
13,206. Food for Infants, &c., F. C. M. Powell, Manchester.
13,207. Attaching Pneumatic Tires to Rims, H. Garratt, Coventry.
13,208. Keeping Bicycles Upright, J. L. Kulp, Brighton.
13,209. Manufacture of Woven Fabrics, T. Ford, Glasgow.
13,210. Driving Gear for Cycles, T. I. Gray, Newcastle-on-Tyne.
13,211. Cutting Rolled Tobacco, W. H. Hamilton and G. J. Allan, Newcastle-on-Tyne.
13,212. Brake for Cycles, S. Jackson and C. T. Roberts, Keighley.
13,213. Driving Chain, &c., for Cycles, G. W. Laybourn, Birmingham.
13,214. Band Brakes for Bicycles, W. Skerry, Newcastle-on-Tyne.
13,215. Drain Joints, C. Foad and C. Gordon, London.
13,216. Propulsion, &c., of Rubber-tired Vehicles, F. E. Walker, London.
13,217. Hackling Machines, H. M. Girdwood, Manchester.
13,218. Fittings for Incandescent Gas Lamps, F. S. Cripps, Surrey.
13,219. Giving Signals on Railways to the Guard, &c., J. and E. Holding and J. Kilgarriffe, Brinscall, near Chorley.
13,220. Crutches, J. Liddle.—(*D. J. Kennelly, United States.*)
13,221. Speed Pulleys, W. M. McIntyre, Manchester.
13,222. Grinding and Polishing Knives, C. F. Ern, Glasgow.
13,223. Candles, F. Bougère, Manchester.
13,224. Teaching Mechanical Construction, T. Birnbaum, London.
13,225. Ventilators, J. West and J. T. Woodhouse, Sheffield.
13,226. Soles and Heels of Boots, G. Barnston, Dartmouth.
13,227. Mattresses, L. Johnston, Handsworth.
13,228. Clips for Securing Inflators, C. T. B. Sangster, Birmingham.
13,229. Spring Clip Attachment, H. T. Davis, Sheffield.
13,230. Drawing Presses, P. F. Holmgren, London.
13,231. Water Gauges, J. S. and J. Jennens, Birmingham.
13,232. Pneumatic Wheel Tires, E. L. Levetus, Birmingham.
13,233. Writing Ink, J. F. Williams, Liverpool.
13,234. Pedal Driving Mechanism, W. H. Dodd, Birmingham.
13,235. Stokers for Firing Boilers, Z. J. Parkes, Workington.
13,236. Tires, J. J. Kempster, London.
13,237. Type-setting Apparatus, G. Barker.—(*L. K. Johnson and A. A. Low, United States.*)
13,238. Waterproofing Solutions, K. A. Frosell, London.
13,239. Cricket Stumps, J. Rowley, London.
13,240. Gas Stoves, A. J. Boult.—(*A. Wunderlich, Belgium.*)
13,241. Speed Gear for Motor Cars, J. R. Rickard, London.
13,242. Artificial Whalebone, W. Hunkemöller, London.
13,243. Inflating Pneumatic Tires, H. South, London.
13,244. Ferric Oxides, A. Crossley and H. A. Allport, London.
13,245. Car Couplings, L. E. Redden, London.
13,246. Hat Beating and Cleansing Machines, C. E. Winterros, London.
13,247. Driving Gear for Cycles, A. B. Genese, London.
13,248. Driving Gear for Cycles, H. M. Genese, London.
13,249. Saddle Pillars for Cycles, H. M. Genese, London.
13,250. Telephonic Apparatus, C. Adams-Randall, London.
13,251. Liquid Measure and Bottle Stopper, H. D. Payne, London.
13,252. Rotary Engines, W. E. Prall, jun., London.
13,253. Sewing Needles, F. W. Golby.—(*J. Zimmermann, Germany.*)
13,254. Boots, F. W. Golby.—(*P. Schlesinger, Germany.*)
13,255. Mantles for Gas Lights, W. L. Voelker, London.
13,256. Mantles for Gas Lights, W. L. Voelker, London.
13,257. Driving Gear for Cycles, A. H. Edwards, London.
13,258. Tires, E. A. Grove, London.
13,259. Coating Surfaces, R. Wallwork and A. C. Wells, London.
13,260. Pneumatic Fire Alarms, A. Goldstein, London.
13,261. Pocket Filters, S. W. Silver and W. Fletcher, London.
13,262. Material for Brewing Beer, B. W. Valentin, London.
13,263. Holders of Electric Lamps, W. L. Preece, London.
13,264. Regulating Electric Motors, The British Thomson-Houston Company.—(*A. H. Armstrong, United States.*)
13,265. Pneumatic Wheel Tires, A. H. Vesey, London.
13,266. Brakes, M. B. Parrington, London.
13,267. Electric Switches, W. R. Daggett and W. H. Heinz, London.
13,268. Mechanism for Waxing Thread, R. Haddan.—(*The Goodyear Shoe Machinery Company, United States.*)
13.269. Production, &c., of Explosives, L. Kelbetz, London.
13,270. Manufacture of Explosives. L. Kelbetz, London.
13,271. Electric Switches, J. B. Verity, London.
13,272. Packing Fish, J. Clarke and J. T. Harvey, London.
13,273. Apparatus for the Manufacture of Inlaid Fabrics, A. S. Oetzmann and S. J. Narracott, London.
13,274. Devices for Opening Envelopes, F. E. Munn, London.
13,275. Lap Boards, S. M. Rivers, London.
13,276. Velocipede Wheels, G. J. Stevens and J. Hix, London.
13,277. Boot Treeing Machines, T. and T. H. Salmon, London.
13,278. Cycle Gear Cases, A. Hess and G. Wuth, London.
13,279. Centrifugal Dryers, R. A. Lister and G. E. Snoxell, London.
13,280. Brushes, C. A. Watkins, London.
13,281. Albumen Tannin, W. L. Wise.—(*Knoll and Co., Germany.*)
13,282. Heating Pipes, H. C. Platts and T. Lowther, London.
13,283. Storing and Transporting Cycles, A. MacGregor, London.
13,284. Photographic Cameras, A. J. Boult.—(*T. H. Blair*, ——.)
13,285. Handles for Cycles, G. H. W. Davis, Birmingham.
13,286. Brake for Cycles, A. L. Strange, London.
13,287. Fishing-rods, H. P. Mundey, London.
13,288. Bicycles and other Vehicles, G. E. Brown, London.
13,289. Tips for Boots and Shoes, J. E. Foort, London.
13,290. Advertising Car, M. Johnson, London.
13,291. Eye Shades, W. G. Honey, London.
13,292. Leaf Holder for Books, &c., W. Wilmore, London.
13,293. Keeping Liquors under Carbonic Acid, A. Friedeberg, London.
13,294. Machines for "Knotting" Nets, M. Woschyllo, London.
13,295. Electrically-controlled Railway Signals, W. P. Thompson.—(*F. McBrien, J. Wayland, and J. H. Fleming, United States.*)
13,296. Burners for Incandescent Gas Light, W. P. Thompson.—(*Niehusen and Zerning, Germany.*)
13,297. Electric Furnaces, R. Pignotti, F. Lori, S. Regnoli, M. Pandaleoni, and M. Besso, London.
13,298. Hernia Truss, H. Loewy, Liverpool.
13,299. Apparatus for Blowing Bottles, D. Laffan, Liverpool.
13,300. Automatic Fog Signalling, A. Jays, W. W. Warren, and R. H. Buckby, London.
13,301. Elevators for Grain, &c., W. R. Turton, Liverpool.
13,302. Apparatus for Tilting Barrels, F. C. Sharman, London.
13,303. Bicycles, W. Evans and G. G. Sharp, London.
13,304. Crank for Velocipedes, G. Clark, London.
13,305. Type-writers, E. von Hülsen, Germany.

SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

556,008. Feed-water Filter, *A. Harris, Middlesborough, England.—Filed May* 16*th*, 1893.

556,008

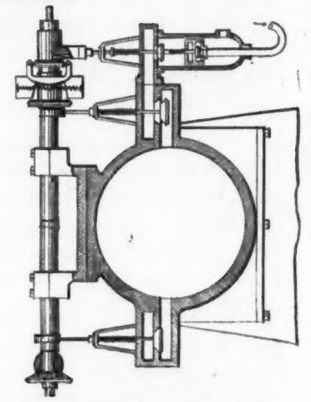


Claim.—(1) In combination with a pipe A D adapted to deliver water from the pump to the boiler, a branch U T from said pipe, a filter in said branch, and an automatic valve B placed in the water supply pipe between the pump and boiler, and weighted to the required resistance, whereby, when the resistance in the filter equals or exceeds the pressure to which the valve is adjusted, the filter is thrown out of action, the current reversed, and the water allowed to proceed direct to the boiler. (2) In combination with a filter for filtering feed-water, of the inlet pipe A, the valve B connected thereto, pipe U between said valve and the filter, pipe D also communicating with valve B, pipe T connected to the filter and also in communication with pipe D, and valves c c^1 and c^2 located as shown and described, whereby when the resistance becomes too heavy the filter is thrown out of action.

556,086. Gas Engine, *H. G. Carnell, Dayton, Ohio. Filed June* 22*nd*, 1895.

Claim.—(1) In a gas engine, the combination, with the gas inlet valve opening into an air-mixing chamber and an inlet valve for the mixture of gas and air opening outwardly, of a check valve opening inwardly, located between the inlet valves and the ignition chamber, with a cone-shaped cam operating upon said inlet valves to open the same, and a governor to shift said cam to vary the valve opening, substantially as shown and described. (2) In a gas engine, the combination, with the gas inlet valve opening into an air-mixing chamber and an inlet valve for the mixture of gas and air opening outwardly, said valves being provided with a common valve stem, of a check valve opening inwardly located between the inlet valves and the ignition chamber, with a cone-shaped cam operating upon said inlet valves to open the same, and a governor to shift said cam to vary the valve openings, substantially as shown and described. (3) In a gas engine, the combination, with the gas inlet valve opening into an air-mixing chamber and an inlet valve for the mixture of gas and air opening outwardly, of a check valve opening inwardly located between the inlet valves and ignition chamber, with a cam for opening said check valve, and a cone-shaped cam for opening said inlet valves, said cams being arranged to hold open said check valve until the inlet valves have been released, with a governor to shift said cone-shaped cam to vary the inlet valve opening, substantially as shown and described.

556,086



556,193. Sheet Metal Rolling Mill, *J. Matthews, Wyandotte, Mich.—Filed May* 20*th*, 1895.

Claim.—(1) In a rolling mill of the character described, the combination with the rear set of rolls, the curved plate and movable roll in rear thereof, of the pivoted guide plate having a roller at its inner end, and a downwardly-depending curved portion and the coiled spring, substantially as described. (2) In a rolling mill, the combination with the three-high and four-high sets, the rolls, platforms and boxes, the guide plates and pivoted guides, of the reversing set of rolls, the curved plate, and movable roll in rear thereof, the pivoted guide plate having a roller at its inner end and a downwardly-depending curved portion and the coiled spring, substantially as described.
